Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.
+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.
+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.
+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

THE
Electrical Engineer.

VOL. XI. JANUARY 7, 1891. No. 140.

HE INVENTORS OF THE ELECTRIC MOTOR.—I.

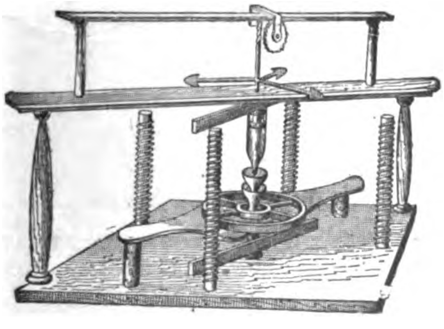
WITH SPECIAL REFERENCE TO THE WORK OF THOMAS DAVENPORT.

BY

Franklin Leonard Pope

> To rightly appreciate a discoverer we should not look at his ork from our time; we should not judge of his work in the full-ess of the light of present knowledge, but in the dim twilight hich alone illuminated him to then unknown—but now well-nown—facts and laws.—ALFRED M. MAYER.

HE electric motor, which but a few brief years ago, was regarded as but little better than a philosopher's plaything, has, with almost startling suddenness, assumed its position as one of the potent factors of modern industrial development. The story of the birth of this great invention has hitherto been given to the world only in part, d even such fragments of its early annals as were once own are now well-nigh forgotten; they linger only in t fading written records, and in the memories of an lier generation, of which the scattered survivors are idly passing from the stage. I have sought, therefore, ile trustworthy evidence is yet accessible, not only from testimony of the few witnesses yet living, but from



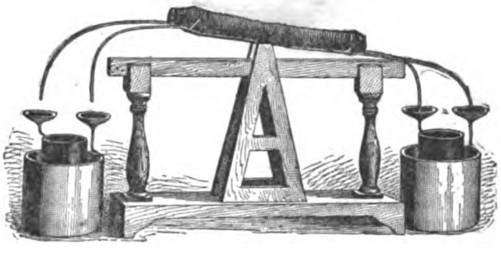
STURGEON'S APPARATUS FOR ELECTRO-MAGNETIC ROTATION.

[*By permission of Charles Scribner's Sons.*]

e time-worn and crumbling pages of contemporaneous nuscripts, to rescue from impending oblivion the true ory of the invention of the electric motor.

It is eminently desirable that we enter upon the field of esearch with a definite conception of what is meant when e speak of the electric motor in the sense of a concrete ganization, in other words as an invention. What, then, t us inquire, is the essence, the fundamental principle, which finds its necessary embodiment in each and every one of the thousands of electric motors which are doing such an important and increasing share of the world's work to-day? The question happily, is not a difficult one to answer. If an expert, skilled in the law of patents, were asked to formulate in legal phraseology a definition which should concisely sum up the new and useful invention embodied in the machine which we know as the electric motor, it might be couched in language something like the following:

The method of producing mechanical power by the application of electro-magnetism, which consists in combining with a suitable source of electricity, two systems of electro-magnets; one system mounted upon a shaft rotating continuously in one direction; the other fixed in relation thereto, and a commutator actuated by the rotation of said shaft, acting to instantly reverse the polarity of one of said systems, when by reason of their mutual attraction, the revolution of the shaft has brought the poles of the moving magnetic system into coincidence with the poles of the fixed sytem.



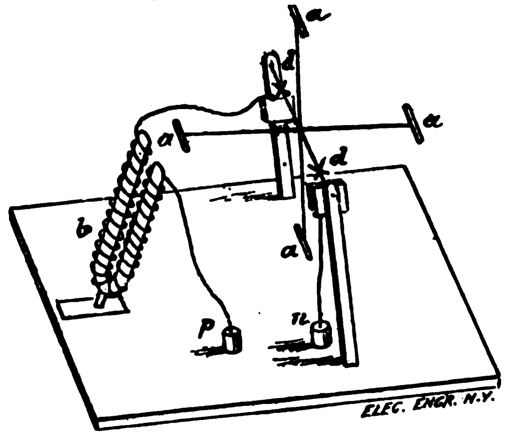
HENRY'S APPARATUS FOR PRODUCING MOTION BY ELECTRO-MAGNETISM.

[*By permission of Charles Scribner's Sons.*]

The above definition, formulated in the semblance of a patent claim, will at once be recognized as embracing the essential characteristics of the practical electric motor as we find it at work in the world to-day. On the other hand, it will be observed that the definition excludes certain special organizations, among which may be mentioned the rotary motor having a field induced by the permanent magnetism of steel; the rotary motor in which the intermittent attraction of electro-magnets is exerted upon a succession of non-polarized soft iron armatures arranged upon the periphery of a wheel, and the reciprocating motor in which masses of soft iron are dragged back and forth by the alternately intermittent attraction of electro-magnets or of solenoids. While it may be admitted that these and some other less well-known devices are not without a certain utility in minor and special applications of electric power, nevertheless, in a broad sense, it may be stated without qualification, that the machine of which a definition has just been given, has no less surely proven its right to be regarded as the accepted type of the modern electric motor than has the double-acting cylinder, piston and crank to be regarded as the accepted type of the modern steam engine.

As in the æolipile of Hero of Alexandria we had an example of rotary mechanical motion by the energy of steam before the advent of the double-acting cylinder and crank, so likewise did we have rotary motion by electro-magnetism before the combination of the reversible and the non-reversible electro-magnets in the magnetic engine. But it was not until the unerring inspiration of the master mind of Watt had grasped the true combination, that the world was put in possession of the steam-engine, that mighty agent which was destined to work its industrial regeneration. It has been my endeavor in the present investigation, to determine to whom should be accorded the distinction of being rightfully regarded as the Watt of the electric motor.

Having gained a clear conception of that for which we are to seek, we may proceed to make a critical examination of the history, written and unwritten, of the childhood of the electric motor.



EDMONDSON'S APPARATUS FOR ELECTRO-MAGNETIC ROTATION.
[*From Silliman's Amer. Jour. Science.*]

Faraday, in 1821, demonstrated for the first time the possibility of producing continuous rotary motion by electro-magnetism—not by the electro-magnet, for this instrumentality had yet to be invented—but by the movement of a magnetized needle in a field of force.[1]

Barlow, in 1826, produced his rotating spur-wheel; founded upon the principle of the movement of conductors traversed by electric currents in the field of a permanent magnet.[2] These experiments were repeated with variations by many others. In 1825, Sturgeon[3] discovered the electro-magnet. In his hands, however, it was but a feeble instrumentality; a few turns of wire arranged in a single layer upon a bar of soft iron.[4]

In 1831, Henry's celebrated paper appeared, containing an account of his improvements in the electro-magnet and his experiments therewith.[5] The results which he described literally threw the scientific world of both hemispheres into a paroxysm of amazement; it marked perhaps the most brilliant epoch in the whole history of electro-magnetism. By winding the soft iron of the magnet with many superposed turns of silk-insulated copper wire, this experimenter succeeded in sustaining, solely by the force of magnetic attraction, a mass of iron weighing more than a ton. The accounts of Henry's discoveries, given to the world in a scientific journal of established reputation, were soon in possession of the eminent physicists of the European capitals, and ere long many busy brains were at work, each in an endeavor to add something, however little, to the masterly researches of the American philosopher.

In the same year, 1831, Henry published another paper commencing with these words:

> I have lately succeeded in producing motion in a little machine by a power which I believe has never before been applied in mechanics—by magnetic attraction and repulsion.
>
> Not much importance however is attached to the invention, since the article, in its present state, can only be considered a philosophical toy; although in the progress of discovery and invention it is not impossible that the same principle, or some modification of it on a more extended scale, may hereafter be applied to some useful purpose.[6]

The piece of apparatus referred to by Henry in this communication has been carefully preserved, and now forms one of the most valued treasures of the cabinet of the College of New Jersey, at Princeton. We give an illustration of it, made from a photograph, from which its construction may be readily understood. A straight horizontal electro-magnet, wound with three insulated copper wires, is pivoted at its centre, so as to be capable of a limited vertical reciprocating motion. Just beneath and parallel to this, a permanently magnetized steel bar is fixed in a horizontal position. The ends of the respective wires of the electro-magnet being properly connected, are arranged to alternately dip into mercury cups affixed to the poles of two opposing voltaic cells, and thereby to reverse the direction of the current through the helix at end of each stroke. The contrivance illustrated the principle upon which Henry thought an electro-magnetic machine might be worked out, but having satisfied his scientific curiosity with this demonstration, he, like Faraday,[7] was quite willing

SHOP IN WHICH DAVENPORT AND SMALLEY CONSTRUCTED THEIR FIRST ELECTRIC MOTOR; NOW OCCUPIED AS A DWELLING.
[*From a recent photograph by F. L. Pope.*]

[1] *Quarterly Jour. Science.* xii, 74. TYNDALL: *Faraday as a Discoverer*, p. 12.

[2] BARLOW: *Essay on Magnetic Attractions, etc.* (2d Ed.) London, 1823, part iii., p. 280.

[3] WILLIAM STURGEON, a celebrated English electrician, born at Whittington, Lancashire, in 1783; was apprenticed in his youth to a shoemaker, but disliking the occupation enlisted in the militia at the age of 19, and two years afterwards in the Royal Artillery. While in this corps he devoted his leisure to scientific investigation and made himself familiar with the leading principles of electricity and magnetism so far as they had then become known to the world. His scientific papers are numerous and of great value, but were sometimes characterized by an amusing exuberance of diction. When writing of his own discovery, the electro-magnet, he was always at his best, as the following extract will bear witness:—

"The superlative intensity of electro-magnets, and the facility and promptitude with which their energies can be brought into play, are qualifications admirably adapted for their introduction into a variety of arrangements in which powerful magnets so essentially operate, and perform a distinguished part in the production of electro magnetic rotations; whilst the versatilities of polarity of which they are susceptible are eminently calculated to give a pleasing diversity in the exhibition of that highly interesting class of phenomena, and lead to the production of others, inimitable by any other means."—*Annals of Electricity*, etc., x., 223.

He was for many years professor of experimental philosophy in the East India Company's military academy at Addiscomb, and in the latter part of his life lecturer on science at the Royal Victoria Gallery, Manchester. Died at Manchester, in December, 1850.

[4] *Trans. of Soc. of Arts*, etc., vol. xliii, pp. 38–52.

[5] Silliman's *Am. Jour. Sci.* xix, 400.

[6] Silliman's *Am. Jour. Sci.* xx, 201.

I never myself attempted to reduce these principles to practice, or to apply any of my discoveries to processes in the arts. My whole attention, exclusive of my duties to the college, was devoted to original scientific investigations, and I left to others, what I considered in a scientific view of subordinate importance, the application of my discoveries to useful purposes in the arts. * * * The only reward I ever expected was the consciousness of advancing science, the pleasure of discovering new truths, and the scientific reputation to which these labors would entitle me.—HENRY: Deposition in Telegraph Case, Morse *v.* O'Reilly.

[7] I have rather however, been desirous of discovering new facts and new relations dependent upon magneto-induction, than of exalting the force of those already obtained; being assured that the latter would find their full development hereafter.—FARADAY: *Experimental Researches.* § 159.

to leave the practical development of the idea in the hands of those who might feel disposed to pursue it.

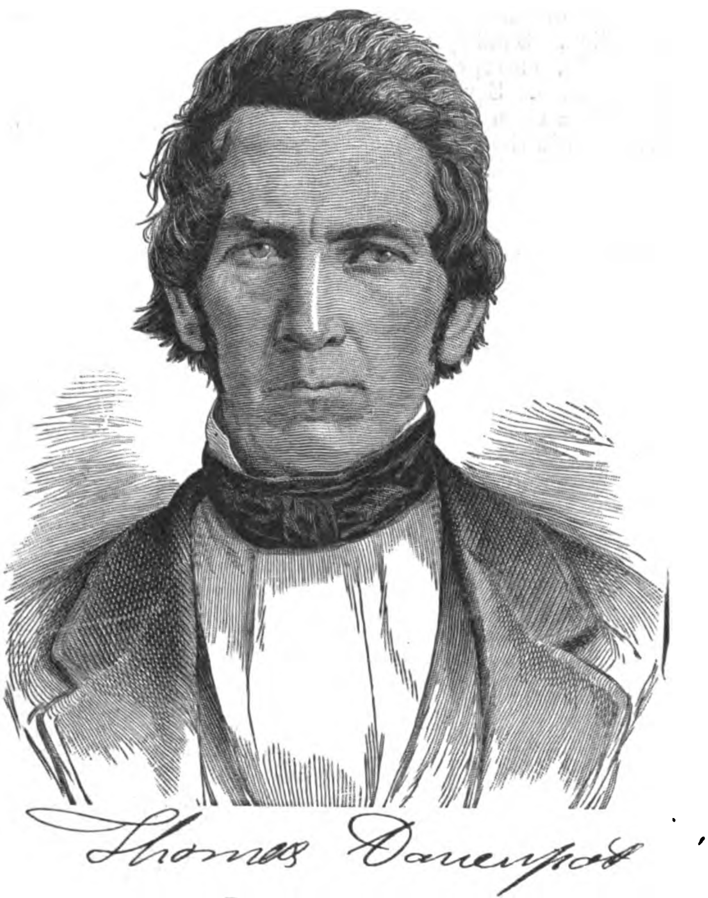
The first published description of an apparatus designed to produce a continuous rotary motion by the agency of an electromagnet is due to T. Edmondson, Jr., of Baltimore, and appeared in 1834.[8]

A fac-simile is given of the illustration accompanying Edmondson's account as published. The apparatus will be seen to consist of a number of neutral soft-iron armatures, mounted upon radial arms affixed to a horizontal shaft. These are successively brought within the sphere of attraction of a stationary electro-magnet, while a commutator is provided by which the magnetizing current is interrupted long enough to permit each armature in turn to pass out of the magnetic field. This appears to be the earliest instance on record of the use of the modern commutator; an elastic contact-spring or brush, pressing against metallic segments fixed upon a revolving shaft.

In 1836, Sturgeon, the inventor of the electro-magnet, published a description of a rotary electro-magnetic engine accompanied by an illustrative drawing, in which he stated that the machine described had been constructed and put in operation as early as the fall of 1832, and had been exhibited before a large audience in London in the spring of 1833.[9]

Sturgeon's apparatus, though usually referred to as the earliest example of an electro-magnetic rotative engine, is in fact little else than a re-arrangement of Ritchie's "revolving magnet," which was described in a paper read by him before the Royal Society, March 21, 1833, and published with an illustrative plate in *Philosophical Transactions*, of that year. The device consisted of a straight electro-magnet, mounted so as to revolve freely upon an upright axis, its poles at each half revolution passing close to the poles of two upright permanent bar-magnets. A mercurial commutator reversed the polarity of the electro-magnet twice in each revolution, as it came opposite the poles of the bar-magnets. Dr. Charles G. Page, then of Salem, Mass., improved this apparatus by the substitution of a metallic commutator, and in this form it became one of the stock pieces of electro-magnetic apparatus in the schools and colleges of America.[10]

The engraving on page 1 is a copy of the illustration given by Sturgeon, from which it will be seen that his machine consisted of two permanently magnetized steel bars turning horizontally upon a vertical axis. The poles of these magnets, as they revolve, are successively attracted by the poles of four upright electro-magnets formed of straight rods of soft iron wound with helices of wire. The details of the commutator are omitted in Sturgeon's drawing, but he explains that the reversal of the polarity of the electro-magnets is effected by permitting the ends of the conducting wires to trail in the segmentally divided vessel of mercury which is seen in the centre of the figure. There is in Sturgeon's description no suggestion of the possibility of substituting electro-magnets for the permanent magnets employed by him.[11]



Thomas Davenport

THOMAS DAVENPORT.

[*From a daguerreotype made in Salisbury, Vt., about* 1850.]

Not long after the publication of the paper of Henry which has been referred to, an attempt was made by parties interested in the Penfield Iron Works at Crown Point, N. Y., to employ magnetism for separating the constituents of pulverized iron ore. A machine was devised, containing a wooden cylinder, the surface of which was armed with a great number of teeth or points of magnetized steel. These were made to revolve continuously through a mass of pulverized ore. The particles of iron were separated from the refuse by adhering to the magnetized teeth, from which they were afterwards brushed off by suitable appliances. In order to charge these magnetic teeth there had been procured, at the suggestion of Professor Amos Eaton, of Troy, from Professor Henry, one of his electro-magnets made of a 1-inch rod, and weighing about 3 pounds. The actuating current for the magnet was supplied by two zinc and copper cells, the plates of which were arranged concentrically upon a plan devised by Dr. Robert Hare. The performances of this electro-magnet, which when excited was capable of sustaining an iron anvil weighing over 100 pounds, were occasionally exhibited for the astonishment of the simple rustics of that somewhat remote region, to whom at that day, the philosophy of electro-magnetism was a thing yet undreamed of. Thus the fame of the Crown Point "galvanic magnet" gradually spread abroad throughout all the surrounding districts.

At the period of which I write, there had grown up in an outlying portion of the township of Brandon, near the foot of the western slope of the Green mountains of Vermont, a scattered village, consisting for the most part of the homes of laborers and other employés of a recently erected blast furnace, which had been christened Forestdale. Among the mechanics whom the temporary prosperity of this new settlement had drawn from other places was Thomas Davenport, a man who had for some years lived and pursued his occupation of blacksmith in the village of Brandon, some two or three miles away. Davenport was at this time about 30 years of age; of somewhat slender physique, but of more than ordinary intelligence and acquirements, considering his educational advantages, which had been limited to those afforded during his minority, by an attendance of six weeks per year upon a common district school in a remote mountain town. He had, however, succeeded in getting possession of some fragmentary portions of a scientific book, which he was wont to pore over while laboring at the bellows of his forge, and by this means had learned at least enough to excite his desire to learn more. Shortly after his removal to Forestdale, Davenport formed the acquaintance of another artisan living there named Orange A. Smalley. Smalley was ten years younger than Davenport, bright, enterprising, and with a natural taste for scientific pursuits. Several years before, while at school at Rochester, a town a few miles distant, he had attended a lecture given in the school-house by some itinerant philosopher of that day, which had served to awaken his curiosity and interest, and so it came about that he and Davenport soon became constant and congenial companions during their brief intervals of relaxation from daily toil. Smalley at this time owned a workshop, and had accumulated a few hard-earned dollars in the diligent pursuit of his trade of blacksmithing and wagon-making. In the course of their intimacy these young men conceived the ambitious plan of increasing their scanty incomes by traveling from place to place during the winter, and delivering experimental scientific lectures. While this scheme was under consideration, and the two were endeavoring to hit upon some new feature which might add to the attractions, and consequently to the profits of their projected entertainment, Davenport chanced to hear a wonderful tale of the performances of the "galvanic magnet" at the Penfield Iron Works. His curiosity was especially aroused by the alleged suspension, by mysterious power, of a blacksmith's anvil, and he accordingly made a journey to Crown Point, 20 miles distant, to witness this extraordinary phenomenon. In this he was disappointed, owing to the inopportune absence of the proprietors. He did, however, succeed in learning that the apparatus had been procured in Albany. With the indomitable perseverance which was ever one of his most marked characteristics, Davenport forthwith set out for that city, determined to purchase a "galvanic magnet," presumably with the intention of utilizing it as one of the star attractions of the projected series of lectures. In due time he arrived in Albany, but inasmuch as he had but the most hazy idea of what the thing was that he wished to purchase, and still less of the locality where he might expect to find it, it is perhaps not to be wondered at that his researches were not crowned with success. It is worth while to quote his own naïve story of his adventures on this quest for the electro-magnet :—

[11] Some other early devices for producing mechanical motion by the action of electro-magnets, but which had no direct bearing upon the ultimate solution of the problem of the motor, nevertheless deserve mention as a part of the general state of the art. Descriptive memoirs of these may be consulted, as follows:

DAL NEGRO, SALVATORE.—*Nuova macchina elettro-magnetica, immaginati dall' Ab. Salv. Dal Negro.* (Annali delle Scienze del Regno Lombardo-Veneto, 10 Marzo, 1834. tom. iv, p. 67.) Padova, 1834.

BOTTO, GIUSEPPE DOMENICO.—*Notizia sopra l' applicazione dell' Elettromagnetismo alla mecannica.* Torino, 1834.

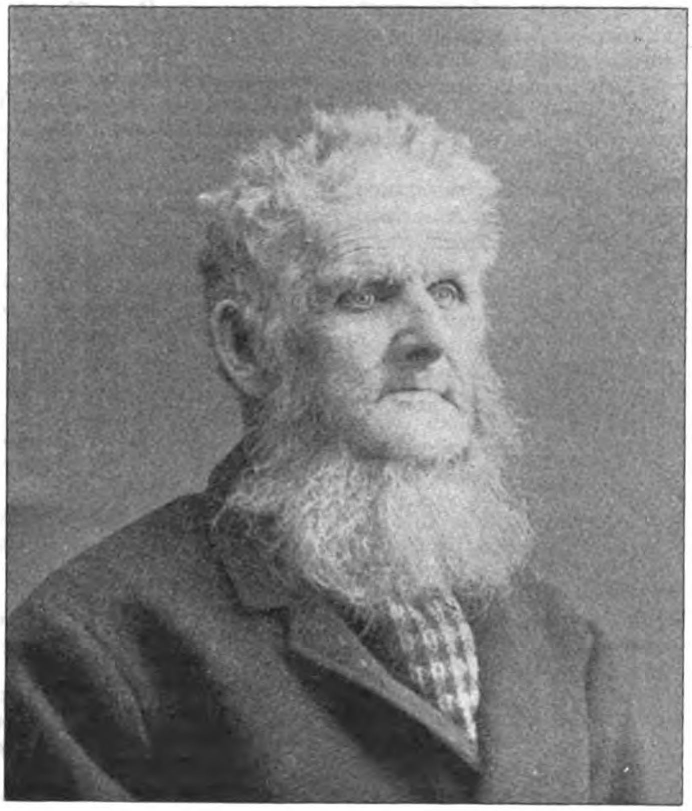
SCHULTHESS, RUDOLPH.—*Ueber Elektromagnetismus, etc.* (Lecture delivered to the Philosophical Society, at Zurich, Feb. 18, 1833), Zurich, 1835. A translation of the two papers last referred to may be found in *Taylor's Scientific Memoirs*, vol. i, part iv, p. 532 et seq.

> As I had been informed that the apparatus was a galvanic battery and possessed powerful magnetic properties, I inquired of my landlord where I should be likely to find a "magnetic battery." He replied that they "made such tubes at the tin-shops for blasting rocks," and directed me there. The tinman sent me to a jeweler's shop where he was sure "they used something of the kind in the manufacture of watches." The jeweler remarked that they had no occasion for such heavy instruments about watches, but advised me to "go to the Eagle furnace where they could cast from any pattern." At this latter place I declined calling and returned home. In December, 1833, I again went to Crown Point with the intention of purchasing some iron, and with high hopes of seeing an anvil suspended between the heavens and the earth by magnetic power. This long-looked-for mystery was finally shown me on my arrival at the Penfield Iron Works; an electro-magnet weighing about three pounds, to which was attached two sets of cups consisting of copper or zinc cylinders to be used in earthen quart mugs. The poles of the magnet were placed upon the face of a common blacksmith's anvil, and as soon as the cups were immersed in the solution of sulphuric acid and water contained in the earthen mugs, the magnet adhered sufficiently to lift the anvil until the battery-cups were removed from the solution. This had to be done by raising the cups out of the mugs, as the conductors were permanently connected together by soldering the battery conductors to those of the magnet. Here was to me one of the wonders of nature and Providence; a new kind of magnetic power! I inquired whether, if the battery cups remained in the solution, and one or both of the conducting wires should be cut in two, on connecting the conductors with the fingers or otherwise, so as to barely bring them in contact, the power would not be suddenly renewed, and as suddenly destroyed by separating them? The reply was that the power of the magnet would be destroyed, for it appeared that they had broken one of the wires which connected the cups with the magnet, and supposing the instrument spoiled, packed it up and sent it to Albany for Professor Henry to repair; whence it had but just returned. I requested the privilege of cutting one of the conductors, and connecting it together for the purpose of ascertaining this fact, but was refused. I demanded the price, and purchased the magnet for the sum of $18, instead of iron which I much needed for my shop. * * * * As soon as I became the possessor of the magnet, I immersed the cups in the solution and then severed one of the conductors, so as to break the circuit of galvanism. Of course I found the magetism wholly destroyed, but on connecting the wires together with my fingers, the magnet became again fully charged. However rapidly the connection and separation of the conductors were made, I found the charging and discharging of the magnet to correspond, and I observed that the magnet produced a hundred-fold more power than was required to make and break the connection.
>
> Like a flash of lightning the thought occurred to me, that here was an available power which was within the reach of man. If three pounds of iron and copper wire would suspend in the air 150 pounds, what would 300 pounds suspend? "In a few years," I said to some gentlemen present, "steamboats will be propelled by this power." A bystander replied, "You mean, sir, magnetic boats." "Truly so," I remarked, "and ere long this mysterious and invisible power will supersede steam; for, shall the mighty agent which suspends this ponderous mass of iron between heaven and earth, serve no other purpose than to excite our wonder and admiration? No! The human mind will not rest with so great a prospect before it, of furnishing a valuable substitute for the murderous power of steam; I venture to predict that the time is not far off, when there will be no more need of legislation and committees of inspection on steam boilers; no more aching hearts and desolate homes in consequence of the awful spectacle of human beings hurled into eternity, but the red lightning of heaven will be soon tamed and will become our servant."

Immediately upon the return of Davenport from Crown Point with the coveted apparatus in his possession, with the co-operation of Smalley experiments were commenced, with the object of producing a machine to be continuously moved by electro-magnetism. Davenport, like Fulton, Morse, Bell and many others of those to whom the world is indebted for its great inventions, appears to have been a man possessing in no unusual degree either mechanical ingenuity, or skill in handicraft. He seems rather to have been a man of broad conceptions and of prophetic foresight; one who could perceive what needed to be done, and who could select the men and the instrumentalities to do it. Above all, he was endowed with a more than common share of that indomitable perseverence and inflexible determination in pursuit of a cherished ideal, which cannot be permanently cast down nor turned aside by any obstacle, however great; which in truth can scarcely be conquered by death itself. Smalley, his associate, was a young man of acute perceptions and keen intelligence; not in any sense a trained craftsman, but rather a typical New England backwoods mechanic, "handy with tools" either in wood and in iron; with a brain fertile in expedients and contrivances to overcome unexpected difficulties. During the greater part of the year 1834, these two worked together in the building still standing at Forestdale, which at that time was occupied by Smalley as a shop. Early in the summer of that year, they succeeded for the first time in obtaining rotary motion by electro-magnetism. A permanently magnetized bar was supported at its centre of gravity like a magnetic needle. By placing the pole of an electro-magnet in proximity to the imaginary circle described by the horizontal swing of the bar, and then breaking the circuit by hand at properly timed intervals, it was found that the bar could be kept in continuous rotation. This proved to be the key to the solution of the problem of the electric motor.

After much further experimentation, Davenport and Smalley finally succeeded in completing an organized apparatus which was capable of maintaining continuous rotation by automatic means. Unfortunately, no drawing of this machine has been preserved, but the following brief description of it, written by Davenport in 1851, will serve to sufficiently explain the essential features of its construction :—

> In July, 1834, I succeeded in moving a wheel about seven inches in diameter at the rate of thirty revolutions per minute. It had four electro-magnets, two of which were upon the wheel, and two were stationary and placed near the periphery of the revolving wheel. The north poles of the revolving magnets attracted the south poles of the stationary ones with sufficient force to move the wheel upon which the magnets revolved, until the poles of both the stationary and revolving magnets became parallel with each other. At this point, the conducting wires from the battery changed their position by the motion of the shaft; the polarity of the stationary magnets was reversed, and being now north poles, repelled the poles of the revolving magnets that they before attracted, thus producing a constant revolution of the wheel.



Orange A Smalley

ORANGE A. SMALLEY.

[From a recent photograph by F. A. Grimes, of Brandon, Vt.]

The electro-magnets used in this machine were copied, with Chinese fidelity, from the Henry magnet purchased at Crown Point, which had been dissected, and the courses and direction of the convolutions of wire in its helices carefully observed. It almost immediately occurred to the experimenters that the speed and power of the machine would be greatly increased by placing a greater number of magnets upon the revolving shaft. Being unable at the time to procure the necessary copper wire for making any more electro-magnets, they tried the effect of substituting permanent magnets, at the same time increasing the number upon the shaft from 2 to 12. The result exceeded their most sanguine expectations; the wheel now revolved at such a rate that the mechanism of the commutator,—which consisted of bent wires dipping into mercury cups, moved by a cam affixed to the shaft—was utterly unable to keep pace with it.

The machine here referred to unquestionably constitutes a complete embodiment of the principles of the modern electric motor, as we have defined them in a preceding paragraph. The description of Davenport agrees in every essential particular with that recently given to the writer, from his own recollection, by Mr. Smalley, who is still living, and although almost an octogenarian, is in full enjoyment of his memory and faculties. He may be seen standing in the photographic view of his old-time shop, which forms one of our illustrations. It may be of interest to state that he did not hesitate to make a journey of several miles on one of the coldest of winter days, in order that the readers of THE ELECTRICAL ENGINEER might be favored by the presentation of the accompanying admirable and characteristic portrait.

The successful outcome of their first attempt at the construction of an electro-magnetic engine, filled the hearts of the experimenters with pardonable elation. They flattered themselves that at least they would no longer be compelled to endure the sarcastic and derisive comments of the neighbors, few of whom could be persuaded that the scheme upon which they were at work could be anything else than the "perpetual motion," which in those less enlightened days was the *ignis-fatuus* of many an ambitious rural mechanic. They met, however, with scant encouragement. The village pastor, when the mysteriously moving machine was shown to him, and the enthusiastic hopes of its constructors were poured into his ear, made the characteristic observation that "if this wonderful power was good for anything it would have been in use long before this." Nevertheless, regardless alike of ridicule, disparagement and poverty—for both were dependent upon their daily toil for the most ordinary necessities of life—Davenport and Smalley prosecuted their experiments with unwearied diligence. From some of the more intelligent of their townsmen, they received now and then a word of encouragement, and it was largely in the hope of being able to satisfy these friends that their ideas were not wholly chimerical, they determined to take the machine to Middlebury, a town 16 miles north, which boasted of an embryo college, and submit it to the inspection of those more familiar than themselves with scientific pursuits, who were presumably qualified to form a competent judgment of its merits.

ST. PAUL'S ELECTRIC RAILWAY SMOKESTACK.

The smokestack of Mr. Tom Lowry's electric railway power house is just 200 feet high, and has an inside diameter at the base of fifteen feet. It took 875,000 brick and 35,000 fire brick to build it. It weighs 19,500 tons and cost $10,000. The flue, which is eleven feet in diameter for one hundred feet from the base upward, is built of fire brick. The casing of fire brick stands like a cylinder within a cylinder, and from the outside wall. The immense furnaces which are to generate steam in boilers which are to operate engines with 7,000 h. p. capacity, would heat the smokestack up for a distance of nearly 100 feet high to such an extent that it would crack unless there was a fire brick casing inside, and this fire brick casing must have room for expansion. The exterior of the stack is octagonal in shape, faced with beautiful white pressed brick, and decorated with cornice work and figures in colored brick.

BOSTON, MASS.—The West End Railway Co. proposes to increase its capital stock by $4,500,000. Its business is growing rapidly.

A SIMPLE TEMPERATURE CORRECTION FOR COPPER WIRE.

BY

Carl Hering.

CORRECTING the resistance of copper wire for temperature involves a formula which, though not complicated, is, nevertheless, too much so to be used in many every-day calculations in which such corrections ought to be made. The writer, therefore, thinks that the very simple method described below may be of use to electrical engineers, as it reduces the temperature corrections to the simplest kind of a calculation.

Although the conductivity of the copper, and the exact diameter of the wire, are subject to variations which may in many cases be greater than the variation due to temperature, yet, in general, it is always best to make corrections as far as practicable. In many cases, as in dynamo work, the temperature correction may be of sufficient importance to necessitate its being made.

Taking as a basis, the Matthiessen standard of resistance of copper proposed by the Committee of the American Institute of Electrical Engineers, namely, 9.612 legal ohms for a wire of pure soft copper, one foot long and one mil in diameter, at 0° C. (=32° F.) and called a "mil-foot" or "circular mil-foot" standard, the writer has calculated the accompanying table. In this table the temperatures have been calculated at which this mil-foot constant has regularly increasing values, the increase being one per cent. between each two successive values. It is therefore in onc sense the reverse of the usual temperature correction tables, which may perhaps be more rational for very exact work, but which are not as rational for facilitating the computing of sufficiently accurate values for all practical purposes.

In the accompanying table the temperatures are given at which the mil-foot constant has values beginning with 10.00 and increasing by regular steps of one per cent. each, that is, steps of 0.1 ohm. To compute the resistance of a wire of any length or size for any temperature, one has merely to use the mil-foot constant given in the table which corresponds to that temperature, or to the temperature nearest to it.

TABLE OF TEMPERATURE CORRECTIONS FOR COPPER WIRE.

Resistance per mil-foot, in legal ohms.	Temperature in Fahrenheit Degrees,	Temperature in Centigrade Degrees.
10.00	50.47	10.26
10.10	55.15	12.86
10.20	59.79	15.44
10.30	64.40	18.00
10.40	68.97	20.54
10.50	73.51	23.06
10.60	78.01	25.56
10.70	82.47	28.04
10.80	86.90	30.50
10.90	91.31	32.95
11.00	95.69	35.38
11.10	100.04	37.80
11.20	104.36	40.20
11.30	108.64	42.58
11.40	112.90	44.95
11.50	117.14	47.30

The constant 9.612 being for 0° C. is of little use for direct calculation, as wires in practice are always at a higher temperature; furthermore, it necessitates multiplying by four figures, besides involving the temperature correction. The mil-foot values in the table, on the other hand, require no further temperature correction, and furthermore involve a multiplication by only two figures, one of which is always unity; for values above 96° F. there are three figures, but two of them are unity. The whole calculation is, therefore, exceedingly simple. The formula for the resistance of a copper wire at any given temperature is, therefore,

$$R = \frac{L}{d^2} K, \quad \text{or} \quad R = \frac{L}{n} K,$$

in which R is the resistance in legal olms at that temperature; L, the length in feet; d, the diameter in mils (thousandths of an inch); n $(=d^2)$, the number of circular mils; and K, the mil-foot constant at that temperature, taken from the table.

Another use of the table is as follows: If the resistance has been calculated with the constant 10.00, which is sufficiently accurate for many cases, and if it is afterwards required to know what the increased resistance is at a higher temperature, say, for instance, 78° F., the table shows that the constant is 10.60, or 6 per cent. higher; it is therefore necessary merely to add 6 per cent. of the resistance to its original value, in order to obtain the true resistance at 78° F. To do this, multiply by .06 and add the result to the original, or what amounts to the same thing, multiply the original by 1.06 (not 10.60), which gives the result directly.

Another use is, when the resistance of a wire, say, at 78° F., is known, and it is required to compute the resistance at, say, 100° F. The constants in the two cases are 10.60 and 11.10; the difference is .5, which is about 5 per cent. It is therefore necessary merely to add 5 per cent. of the original value at 78° F. to obtain that at 100°. The same value is obtained by multiplying the original by 1.05. This correction is, however, not strictly accurate, but it is a very close approximation and is sufficient for almost any case.

Another advantage of the table over the usual formula is, that it shows at a glance how much any given temperature will increase the resistance of a wire.

For intermediate values of the temperature it will be sufficiently accurate to assume a proportionate difference; that is, if the temperature is halfway, for instance, between the two values given, the mil-foot constant will be halfway between the two corresponding values. But as the temperature values differ by only about 4.5° F., such a correction will seldom be necessary in engineering practice.

The table was calculated accurately from Matthiessen's formula and the values given are therefore quite correct, assuming the formula to be correct.

The formula used is the same as is recommended by the committee above mentioned, namely:

$$R_t = R_0 \left(1 + .00387\, t + .00000597\, t^2\right).$$

This formula was solved for t, but as this gives a very complicated expression, it was reduced so as to bring it to the most practical form for calculations; it then becomes

$$t = \sqrt{(R_t - 3.5836)\ 17427.} - 324.12;$$

where t is in Centigrade degrees; R_t is the resistance in legal ohms at the given temperature; the value of R_0 which enters into the constants is 9.612 legal ohms.

THE MAYER ELECTRIC MOTOR.

THE accompanying engravings illustrate a novel type of motor which was designed and has recently been patented by Mr. Max Mayer, of this city. The aim of the designer was to produce a cheap, slow speed motor of high efficiency and the very best of mechanical workmanship. This is accomplished by the extreme simplicity of the machine and by the use of laminated iron for the whole of the magnetic circuit.

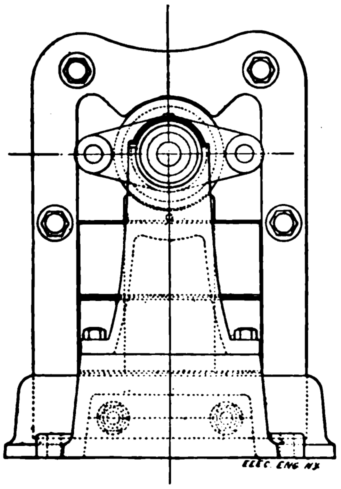


FIG. 1.—THE MAYER MOTOR.

As will be seen in Figs. 1, 2 and 3, the motor is of the single magnet two-pole iron clad type in which the whole of the magnetic circuit is stamped out of one sheet of Swedish iron, the sheets being bolted together to form the magnet frame. Both the plates and bolts are thoroughly insulated from each other to prevent the generation of Foucault currents. The field coils which are two in number are separately wound on brass spools and the height of each is slightly less than the distance between the pole pieces, thus allowing them to be slipped over the core. The whole is secured by means of two pins at alternate corners. By this method of construction there are no joints in the magnetic circuit, and consequently no leakage is due to that cause. The absence of all joints adds greatly to the mechanical stability of the machines.

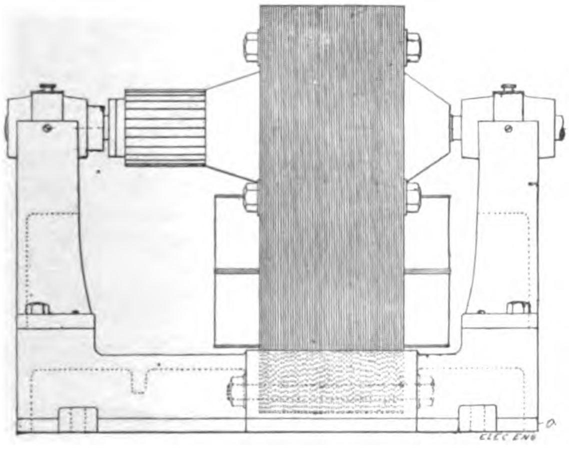

FIG. 3.—THE MAYER MOTOR.

The $\frac{1}{8}$ h. p. motor, shown in Fig. 2, has a modified Siemens armature running in bronze journals and is bolted to a wooden base by means of angle pieces, as shown. The motors from $\frac{1}{2}$ h. p. up have the plates bolted to an iron base having iron standards and self-oiling bearings, thus giving sufficient strength for the larger sizes of motors. The automatic motors are plain shunt wound and there is but a slight variation in speed between full load and no load, this being due to the great strength of field and the low resistance of the armature. There is no sparking with varying loads, the magnetism of the field greatly overpowering that of the armature, even when the machine is working at full load. The mechanical details have been carefully worked out and special care has been taken to make every part as strong and substantial as possible. The shaft is ample in size and is made of the best quality of machinery steel. The bearings are phosphor bronze and are long in proportion to their diameter. The commutator is made of Tobin bronze insulated with mica throughout and thoroughly backed. The rocker arm, brush holders, etc., are very substantial and are all adjustable.

The starting switch has a slate top, thus making the same incombustible. The machine has undergone a thorough test both as a dynamo and as a motor, and has proved to be very efficient and smooth running. There is no external magnetism whatever perceptible, which adds greatly to the efficiency of the machine, it being evident that only those lines of force are effective in the generation of currents which are cut by the armature. The well known danger of magnetizing watches is also prevented.

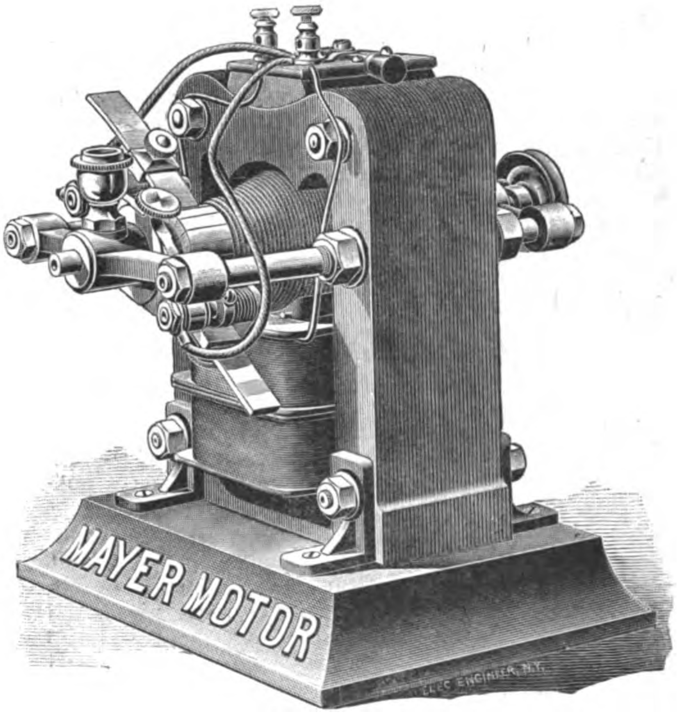

FIG. 2.—THE MAYER MOTOR.

A MUNICIPAL PLANT FOR WHEELING, W. VA.

At the last meeting of the City Council Committee on Lights and the Board of Gas Trustees, to consider the estimates on the 400-light plant for the city, Secretary Franzheim read a number of estimates from various companies. The Westinghouse Company estimated the plant to cost $101,250, and the annual running expenses at $16,000. The Fort Wayne Company put the price of the plant at $75,000, and the running expenses at $10,000. The Western Electric Company figured the plant at $61,000, and the National Electric Company, at from $65,000 to $70,000. The Thomson-Houston Company had made an error in its estimate, including only 200 lights. Mr. John Young, of Chicago, representing the Western Electric Company, stated that his $61,000 estimate provided for duplicate engines and an extra dynamo, making a complete plant.

The committee instructed Secretary Franzheim to report to Council in accordance with the facts, and to name the probable cost of the plant at from $60,000 to $80,000.

The local Wheeling Electrical Company is to have its bid in at the same time.

NEW EXPERIMENTS IN MAGNETISM.

BY

A. E. Dolbear

It has long been known that a common sewing needle will float if carefully placed upon a surface of water; also, that if the needle be magnetized it will assume a position in the magnetic meridian. Iron and steel filings will also float and they can be sprinkled upon the liquid surface nearly as well as upon a solid. If the pole of a magnet be brought near to the floating particles they will respond to the solicitations of the magnetic field in a very free and easy manner.

Let a strong U-magnet have its poles brought near to the iron filings and they will at once arrange themselves in the well-known forms, the lines being plainly seen. The induction, of course, causes adjacent particles to assume opposite polarities and consequently touch each other when free to move. If, now, the field magnet be removed the filings will retain their arrangement and if it be in a vessel large enough to permit the rotation of the whole body it will swing into the magnetic meridian if it did not happen to be in it at first, thus showing that the *arrangement* constitutes the magnet and that as a whole it possesses a magnetic field upon which the earth's field can act.

Now bring gently near the floating magnet one pole of a bar magnet. If this be presented to one of the poles of the particles it will be attracted towards it, and the whole body will rotate more or less, but this must be done slowly else the arrangement of filings will be broken up. The opposite pole will, of course, under similar conditions, exhibit repulsive action and the whole will swing about.

If, now, the magnetic pole be brought near to the middle of the arranged filings, some of the groups will be more or less disintegrated from the rest and will rotate upon a vertical axis and quite turn round. The opposite pole presented will cause them to rotate back again. Great numbers of these can be seen to turn thus whenever a pole is thus presented.

This phenomenon is evidently precisely the same in character as that illustrated at length by Ewing in his late investigations into the constitution of magnets, wherein he used small magnetic needles mounted upon pivots. The above experiments can be tried in a saucer of water, but the whole is capable of being projected with the vertical attached to a lantern and the movements of all sorts seen upon a screen with ease and very little painstaking.

THE BERGMANN CEILING BLOCK AND PENDANT LAMP SWITCH.

Among the novelties now being brought out by the Bergmann Electric and Gas Fixture Co. are the ceiling block and pendant lamp switch, illustrated in the accompanying engravings, Figs. 1 and 2. In designing the ceiling block, the object had in view was to obtain a form which should be easy of inspection and should, at the same time, readily admit of the renewal of the fuses in case of a burn-out. To accomplish this, the block is made in two pieces, of porcelain, the base piece being screwed to the ceiling, and upon this is mounted the cover block. To both these blocks are secured a pair of contacts and between these are slid in two small clips. These consist of pieces of vulcanized fibre, which carry at each side brass pieces which make contact with the corresponding pieces in the block and cover. The insulating piece is grooved diagonally and within the groove is laid the fuse wire, which connects with the two brass pieces at the end. There is thus formed a complete circuit from the top to the bottom block through the fuse wire. Should a burn-out occur, all that is necessary is to slide out the fuse clips and insert fresh ones, which can be done without disturbing the cover in the least.

Much difficulty has been experienced in manipulating pendant lamps, and as they are suspended freely the use of both hands is as a rule necessary. To avoid this, the lamp switch shown in the accompanying engraving has been designed. The switch employed is the well-known Bergmann "Universal," and the flexible wires, after passing through, are made to do the double duty of carrying the current and operating the switch; for this purpose they are led through the switch arm and hang from the end of the arm with the lamp at the end. To turn on the switch, therefore, it is only necessary to pull down the lamp, the construction being such that, as soon as released, a spring carries the lever arm back to its original position; a similar pulling down operates the switch to extinguish the lamp, so that the same motion serves to light or extinguish the lamp at will. The switch is neatly encased in a brass cover and mounted on a porcelain base.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—VIII.

(*Copyright, The Electrical Engineer.*)

BY

Herbert Laws Webb

ACCESSORIES.

ANOTHER very useful accessory on a testing table is illustrated in Fig. 28. It consists simply of a brass plate carrying a number of binding posts and serves for connecting the various instruments to earth. Connection with earth is required in several tests and the brass earth plate makes a very neat job of the connections, which, if made by simply twisting the wires together, would present anything but a sightly appearance, to say nothing of the risk of poor contacts. The end terminal of the plate is connected to a good earth by means of a substantial lead, and when it is necessary to put any of the keys or instruments to earth, the only operation requisite is to run a wire to one of the spare binding-posts of the plate.

An improvement I would suggest on this plate is that it be made in two parts, one part carrying the terminal to which the earth wire is connected and the other the remaining terminals for the instrument connections. The two sections of the plate could be connected or disconnected by the insertion or removal of a plug. It is sometimes necessary, as when testing two wires looped at the distant end for conductor resistance, to remove the earth connection, and the simplest method of doing this is by taking out a plug. If the wire is taken off the binding post it is apt to be overlooked afterwards and cause trouble, but the absence of a plug from its proper place is more noticeable.

PRACTICAL TESTING.

The reader has now been introduced to the various instruments used for cable testing, and next in order are a few definite directions touching on the manner of using them so as to obtain useful results. What may be called the theory of the different tests, and the action that goes on during their application, have already been explained and illustrated diagrammatically in Figs. 1, 2, 3, 4, 5, 6 and 7. The diagrams that follow show the actual connections of the instruments for making the different tests, and a comparison of the two sets of diagrams should give a very clear idea of the subject of practical testing.

In the earlier diagrams, some of the keys and connections were omitted in order that the path of the current and its action might be made as clear and intelligible as possible, and the appearance of each pair will therefore differ materially; but nevertheless no difficulty should be found in understanding the relations between them, and it has been my endeavor throughout to make explanations and descriptions, even at the risk of prolixity, so detailed and full that even those who have never seen a set of testing instruments (if such there be), might be able to derive a clear idea of how the work is done and what goes on during each test.

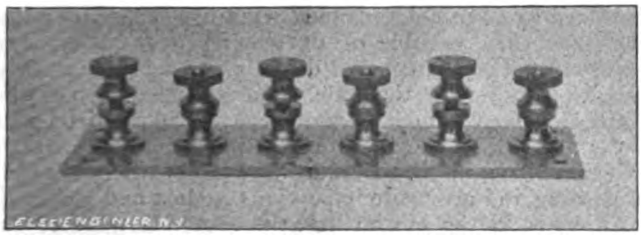

FIG. 28.—BINDING POSTS FOR EARTH CONNECTION.

THE GALVANOMETER CONSTANT.

Before testing a wire for insulation it is necessary to take the constant of the galvanometer in order to obtain a value with which to compare the deflection given by the wire or cable. The connections for taking the galvanometer constant are shown in Fig. 29.

A high resistance of 100,000 ohms, or one megohm, is placed in circuit with the battery and galvanometer, which is shunted with the $\frac{1}{999}$ th or $\frac{1}{99}$ th shunt, and the deflection obtained by a steady application of the current is the constant of the galvanometer. The battery power should be the same as that used for testing the cable, or if the galvanometer is so sensitive that, with the full battery, too large a deflection is obtained, half the number of cells may be used and the resulting deflection doubled. A better plan, however, is either to use a very high resistance or to shunt the galvanometer with a low resistance so that the full number of cells will give a readable deflection.

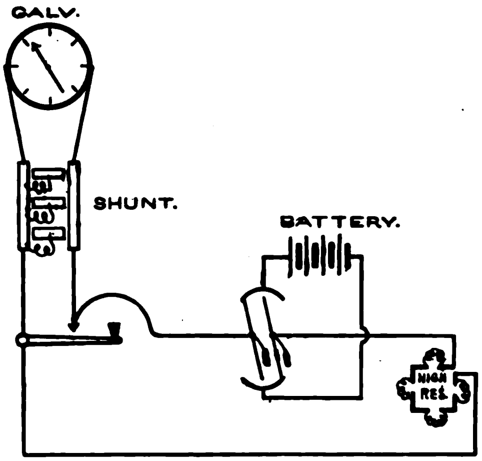

FIG. 29.—CONNECTIONS FOR TAKING GALVANOMETER CONSTANT.

Tracing the connections in the diagram we see that one side of the battery key is connected to one terminal of the short circuit key, the other side of the battery key going to earth. The opposite side of the short circuit key is connected to the high resistance, which is also connected to earth from the other side. The wires from the shunt are taken one to each terminal of the short circuit key. When the current is turned on the circuit is established through the lever of the short circuit key and the high resistance. On depressing the lever of the short circuit key the galvanometer is thrown in circuit and the deflection is obtained. By tapping the short circuit key a few times the needle will be moved gradually along the scale instead of swinging far beyond the mark and oscillating for some time; with a little practice the short circuit key may be so manipulated that very little time is lost in bringing the needle to rest, either at the figure of the deflection or back to zero before turning off the current. The deflection should be the same with both poles of the battery; if there is any appreciable difference the suspension is probably slightly twisted or the battery is inconstant, probably owing to bad insulation.

Assuming that the constant is taken with a battery of 100 cells, a high resistance of 100,000 ohms and a shunt in the galvanometer circuit of $\frac{1}{999}$ th, and a deflection on the scale of 300 divisions is obtained, this result should be written down as follows:

Galvanometer Constant: 100 cells, 100,000 ohms, S $\frac{1}{999}$, def. 300=30,000.

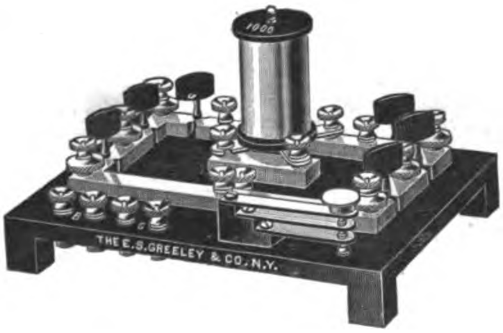
The last figure, thirty-thousand, is the deflection that 100 cells would give through one megohm with no shunt in the galvanometer; or, in other words, 100 cells would give a deflection of one division on the scale through a resistance of 30,000 megohms.

To obtain the grand constant the deflection observed is multiplied by the power of the shunt used and by the resistance in circuit. In the case imagined the multiplying power of the shunt is 1,000 and the resistance $\frac{1}{10}$th of a megohm; consequently the grand constant is $300 \times 1000 \times \frac{1}{10} = 30,000$.

In noting down the galvanometer constant on a test sheet it is best to give all the details of number of cells, shunt and resistance employed, and the deflection obtained, in the form given above. If necessity should arise at any subsequent date for examining the report no doubt can then arise as to whether the same battery was employed throughout the test, or whether the constant was correctly calculated; and if all the data is properly noted down the test can be worked out again should there be any doubt as to the results; whereas if these details are omitted there is no check on the correctness of the working or the reliability of the test.

THE FREY ELECTRICAL BALANCE OR REVERSIBLE BRIDGE.

This instrument, designed by Mr. Charles P. Frey, chief electrician of the E. S. Greeley Electrical Laboratory, is specially adapted for rapidly measuring both high and low resistances, with unusual precision. It is intended to be used in connection with an adjustable resistance box or a B. A. pattern standard coil, and takes the place of the bridge coils which form part of the rheostat of the conventional pattern. The peculiar feature of the instrument is that its bridge coils can be tested by reversing or interchanging them, an operation which can be speedily performed. Should any inequality exist it can be quickly corrected. Both bridge coils are shunt wound upon one spool and can be removed to give place to others of higher or lower resistance. A wire bridge with subdivided half-meter scale can also be attached. This apparatus is being placed on the market by The E. S. Greeley & Company, New York, proprietors of the Greeley Laboratory.



The Frey Electrical Balance.

MR. FERRANTI ON HIGH PRESSURE INSULATION.

In a communication to the London *Electrical Review*, Mr. S. Z. de Ferranti writes as follows:

To begin with, I may say that the amount of "wild talk" about 10,000 volts is quite unwarranted, especially as the people who speak about it have, practically, no knowledge on the subject. 10,000 volts, although it can be worked, and machinery and cables made to stand it, is not a thing which at the present moment is as easily dealt with as some people may imagine. Moreover, I may say that a cable which has to be used for a daily supply of 10,000 volts must be able to stand a very prolonged test of 25,000 volts at least, with a considerable h. p. at the back of it.

Now, as regards the statement as to the abandonment of the Fowler-Waring cable by the London Electric Supply Corporation, Limited, I may say that this is quite incorrect. The only trouble that there has been with the Fowler-Waring cables has been in what they have been called, not in the cables themselves. They were, and are, first-class cables for the purpose for which we are using them, viz., the supply of current at 2,500 volts. If the cables were required for a higher pressure they would have to be more heavily insulated, and this no doubt can easily be understood.

I may also add that our permanent distributing work is being done with insulators other than India-rubber, and that I do not propose to use India-rubber where I wish to have a lasting permanency.

THE NEW BAXTER ELECTRIC RAILWAY MOTOR.

Among the names of those who early entered the field as designers and builders of electric motors, none is perhaps better known than that of Wm. Baxter, Jr., of Baltimore, whose arc motors have long held an enviable position among the successful machines of to-day. More recently, however, Mr. Baxter has devoted much of his attention to the designing of constant potential motors and more particularly to electric railway motors.

Recognizing the acknowledged disadvantages now encountered with high speed motors employed in that service, Mr. Baxter has accordingly started out at once with the idea of reducing the speed of the armature, so as to avoid all intermediate gear. A reduction of speed of armature, other things being equal, necessitates a corresponding increase in torque, and to effect this the multipolar motor has been adopted by Mr. Baxter; but the problem of arranging such a machine under the car, with sufficient clearance between the ground and motor, was by no means a simple one; but it has been successfully solved with the additional important advantage of a reduction in weight of the motor mechanism.

In order to demonstrate the thoroughly practical character of the new motor, a large number of invited guests, including the Mayor and many of the prominent citizens of Baltimore, as well as others from New York, Boston and Washington, assembled at the works of the Baxter Electric Motor Co., at Baltimore, on Dec. 27, where the car was put through a most severe series of tests. The track, situated on the grounds of the company, was about one-eighth of a mile in length and included four sharp curves and a grade of three per cent. With every available space on the car occupied by the visitors, no difficulty whatever was experienced in starting and stopping on curves and grades, the smoothness of starting under these conditions being especially noteworthy.

The manner in which these results have been accomplished will be understood from the description of the motor and gear arrangements which are illustrated in the accompanying engravings.

Mr. Baxter has adopted a machine having eight poles energized by four field magnet windings. Two of these machines, each capable of developing over 20 h.p., are employed. They are geared directly to each axle at both ends, thus relieving the axle from all unequal twisting strain. The steel pinions on the armature and cast-iron gears on the axles are encased in dust and waterproof cast-iron casings and run in oil. Besides this, the bearings are self-lubricating and are made impervious to dust and grit.

As shown in the engravings, the motor is flexibly suspended in every direction and its free end is attached to a suspension frame which rests on the springs that support the central portion of the car body. This suspension frame moves with the car body and thus has all its elasticity of motion. By this method of suspension the danger of breaking the circuit connections to the motor is avoided, as the points to which they are attached move together with the car body and thus always preserve their relative positions.

Another important feature of the mechanical construction consists in the position of the brushes; the motor being an eight-pole machine, the brushes are placed at an angle of 45 degrees and directly on the top of the machine, Thus, by removing the trap door in the floor of the car both brushes can be readily got at. The brush holders, which are very substantially constructed, hold the carbon brushes firmly and free from vibration, and permit of the ready removal of the brushes.

The armature employed has a diameter of 18 inches and the field magnets are, by an ingenious design, so shaped that, notwithstanding the employment of eight poles, the extreme height of the motor does not exceed 19 inches. As a result, the car body does not require to be raised above the ordinary height and the machinery is still over 5 inches above the level of the track.

The speed of the armature is equivalent to 42 turns per minute per car mile, so that at a speed of 7 miles per hour the armature revolves at only 294 revolutions. To obtain this speed the pinions on the armature shaft are 4½ inches in diameter and mesh with 18 inch gears on the axle, the car wheels being 30 inches in diameter.

The torque at the periphery of the armature is 175 lbs. with 15 amperes, 350 lbs. with 22½ amperes, and 530 lbs. with 30 amperes, the torque at the pitch line of the gears being evidently four times the torque on the armature.

The economy in weight effected by the construction adopted will be appreciated by the following table of weights:

Weight of 4 field magnets	340 lbs.
" " armature	205 "
" " commutator and shaft	150 "
	695 lbs.

If we add to this 200 lbs. for the weight of the frame we have approximately 900 lbs. as the entire weight of the motor proper. The weight complete of the power mechanism for each motor, including gears, shaft, casings, etc., does not exceed 1,500 lbs., thus showing excellent economy in weight.

With 900 lbs. weight of motor proper, therefore, and having with 30 amperes a torque of 530 lbs., at the periphery of the armature 18 inches in diameter and running at 300 revolutions per minute, we obtain the following -power.

$$\frac{4\frac{2}{3} \times 300 \times 530}{33,000} = 22.4 \text{ h. p.}$$

This gives, therefore a weight of 900 + 22.4, or 40.4 lbs. per horse-power of motor. If, instead of 300 revolutions, the motor were run at 1,000 it would then actually develop no less than 77 h. p., equivalent to a weight of 11.7 lbs. per horse-power.

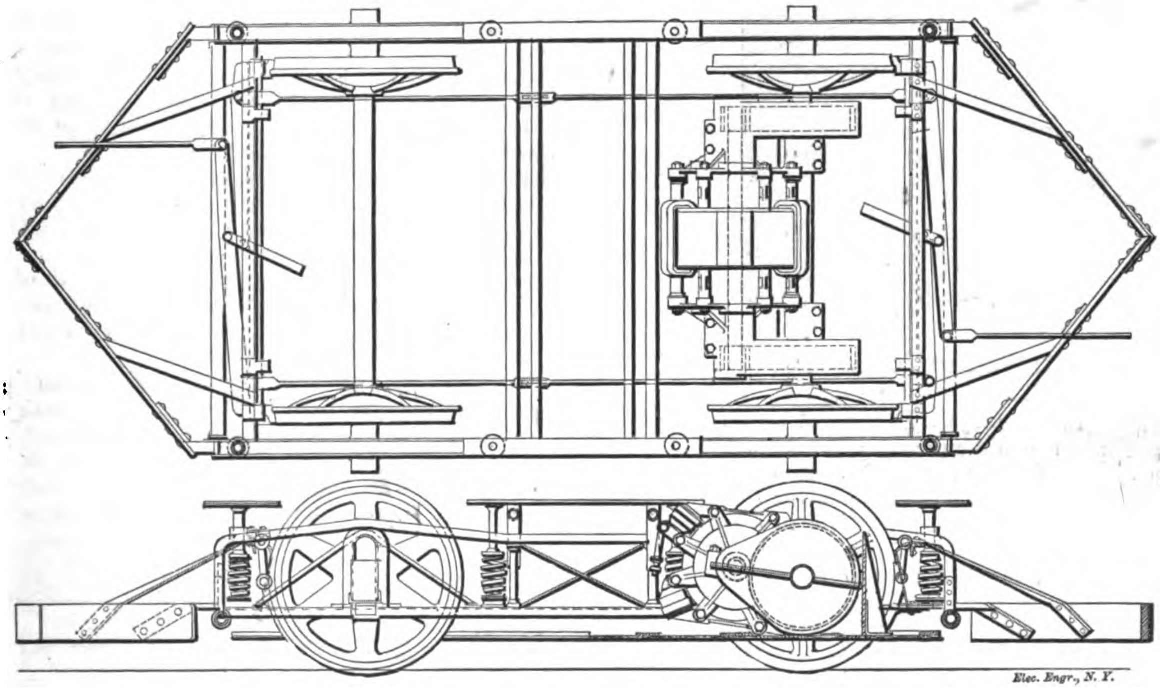
We come now to the electrical details which have been very carefully worked out. The exposed position of a street car motor makes the question of insulation one of paramount importance and to effect this in the most complete manner, Mr. Baxter has so designed the machine that the armature core as well as the commutator hub are entirely insulated from the shaft. The armature coils, in addition, are insulated from the core with mica.

The motor is series wound and each of the four field magnets is subjected to an induction of 5,000 ampere turns. The iron cores weigh each 67 lbs. and are built up of laminated soft iron; they are wound with 203 turns of No. 9 wire, weighing 18 lbs. The total resistance of the fields which are all in series is therefore 1.4 ohm.

The armature is 18 inches in diameter and 9 inches face. It is wound in 136 sections connected to a like number of commutator bars. Each section consists of 12 turns of No. 11 wire, and the total resistance of the armature is 1.03 ohm. As stated above, the brushes are placed at an angle of 45 degrees.

The car is governed entirely by the manipulation of a single crank lever under the control of the driver, the car going ahead, or reversing, in the same direction as the movement of the crank lever, and the speed being exactly in proportion to the distance through which the crank is turned. The regulation is effected by means of a rheostat which is completely fireproof and of the most simple construction. The resistances are constructed so as to possess considerable self-induction as a protection for the armature against lightning. To this end the lightning srrester is connected to the trolley wire, and the rheostat placed between the armature and the lightning arrester. The high counter E. M. F. of self-induction of the rheostat therefore forces the lightning charge to take the path to ground through the arrester, in preference to the armature, thus leaving the latter unharmed.

These constitute the salient features of the Baxter railway motor, which has been constructed under the superin-



FIGS. 1 AND 2.—BAXTER ELECTRIC RAILWAY SLOW SPEED MOTOR.

tendence of Mr. David E. Evans, superintendent of the Baxter Electric Motor Company, and which seems to possess all the qualities which will insure success in actual practice, as was abundantly demonstrated in the recent test.

THE BERGMANN AUTOMATIC SWITCH.

In wiring buildings it is rarely the case that switches, which must be conveniently located, can be inserted directly in the line leading from the main or branch to the lamps. In the majority of cases, therefore, considerable lengths of conductors are practically wasted in making a detour from branch to switch and from the switch to the lamps; and where the latter are at a considerable distance from the switch the loss in conductors may reach a considerable item.

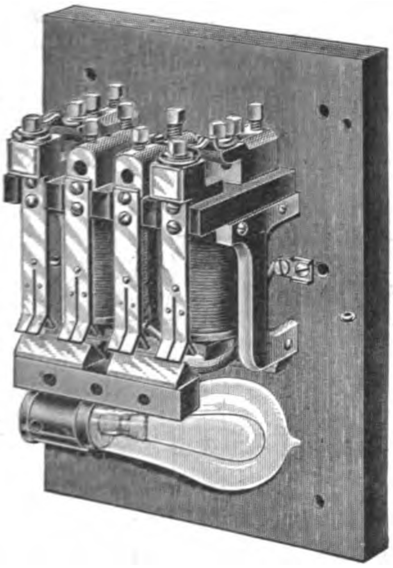


Fig. 1.—Bergmann Automatic Switch.

An arrangement, therefore, in which the switch can be placed close to the lamps and directly in the line of the conductors and operated by small wires from a distance will be acknowledged to be a valuable addition in the wiring equipment of a building and this has been successfully accomplished in the new automatic switch just brought out by the Bergmann Electric & Gas Fixture Co., of this city, which is illustrated in the accompanying engraving, Fig. 1.

As will be seen, the switch consists of a pair of electro-magnets, an incandescent lamp for a resistance, and the switch proper.

Two push buttons are necessary to operate it, one to close the circuit for lighting, and the other to extinguish the lamps by opening the circuit.

The operation of the switch will be readily understood by referring to the accompanying diagram, Fig. 2. As will be seen, the mains, M^1, M^2, are connected to one set of contacts and the contacts between them are joined to the branches B^1 and B^2 in which the incandescent lamps are included. The push buttons, which are mounted in a small box conveniently placed, are connected by fine wires, P^1, being connected to the main M^1, and P^2 with the branch B^2, the one being negative, the other positive. The third wire to the push button is joined between the lamp L and the switch magnet SM, as shown.

It will now be readily seen that when the button P^1 is pressed the circuit is closed through the electro-magnet SM, which attracts the armature A and closes the contacts through the clips *c*. As soon as the button is released, the circuit is established between the switch magnet and the lamp L in series, so that the current passing through lamp and magnet is immediately cut down to one-tenth of an ampere and remains at that while the switch is closed.

When it is desired to cut out the lights, the push button P^2 is pressed, which short circuits the switch magnet SM and allows the armature A to be retracted by the spring, thus opening the switch.

As the current used to operate the switch is about one-tenth of one ampere, a very thin wire will carry the current to the push buttons. In a house installation every circuit may now be controlled with a few neat push buttons in the hall-way where unsightly hand-switches would not be tolerated.

It is evident that any number of push buttons may be attached to the same switch so that any circuit may be controlled from any point desired. Thus, in ordinary house lighting every floor can be controlled from each floor; for instance, if three floors were to be controlled it would only be necessary to run three thin wires from top to bottom connecting respectively with switch No. 1, 2, and 3. With three push buttons on each floor, every switch can be operated from any floor.

The switch can be utilized for a great variety of purposes, for many of which it would be impossible, or too costly, to apply the ordinary hand-switch, such as running electric elevators; here the operator merely handles a small lever or controls his car with two push buttons.

It also enables motors for any purpose to be controlled from any desired point.

In buildings where the current is generated locally, each floor or circuit can be operated from the dynamo room with push buttons and thin wires connected to the switch. The main or lighting circuit would consist in this case of one pair of mains running the entire length of the circuit with a switch at each branch, thus saving the cost of running separate wires from the dynamo room to each circuit, as is now the general practice.

For store or office lighting the switch can be operated by a clock so as to connect the lights at a certain hour and also to disconnect them at any desired time. For electric heating, in conjunction with a thermometer or thermostat the switch constitutes an absolute temperate regulator. By connecting the switch to a burglar alarm system the lights all through a building can be thrown on the moment a door or window is opened. Many other applications of the switch which is made in all sizes will suggest themselves to our readers, and its appearance marks a distinct advance in electric wiring appliances.

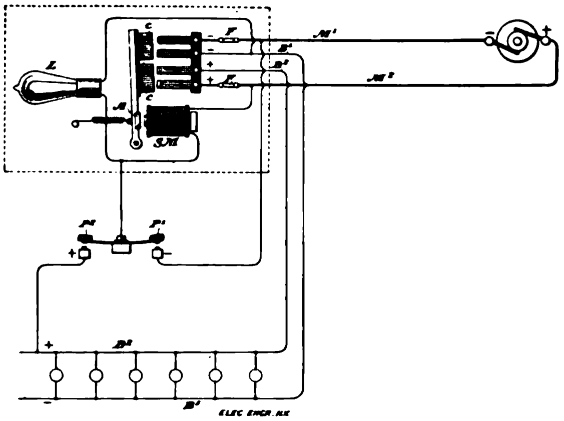

Fig. 2.—The Bergmann Automatic Switch.

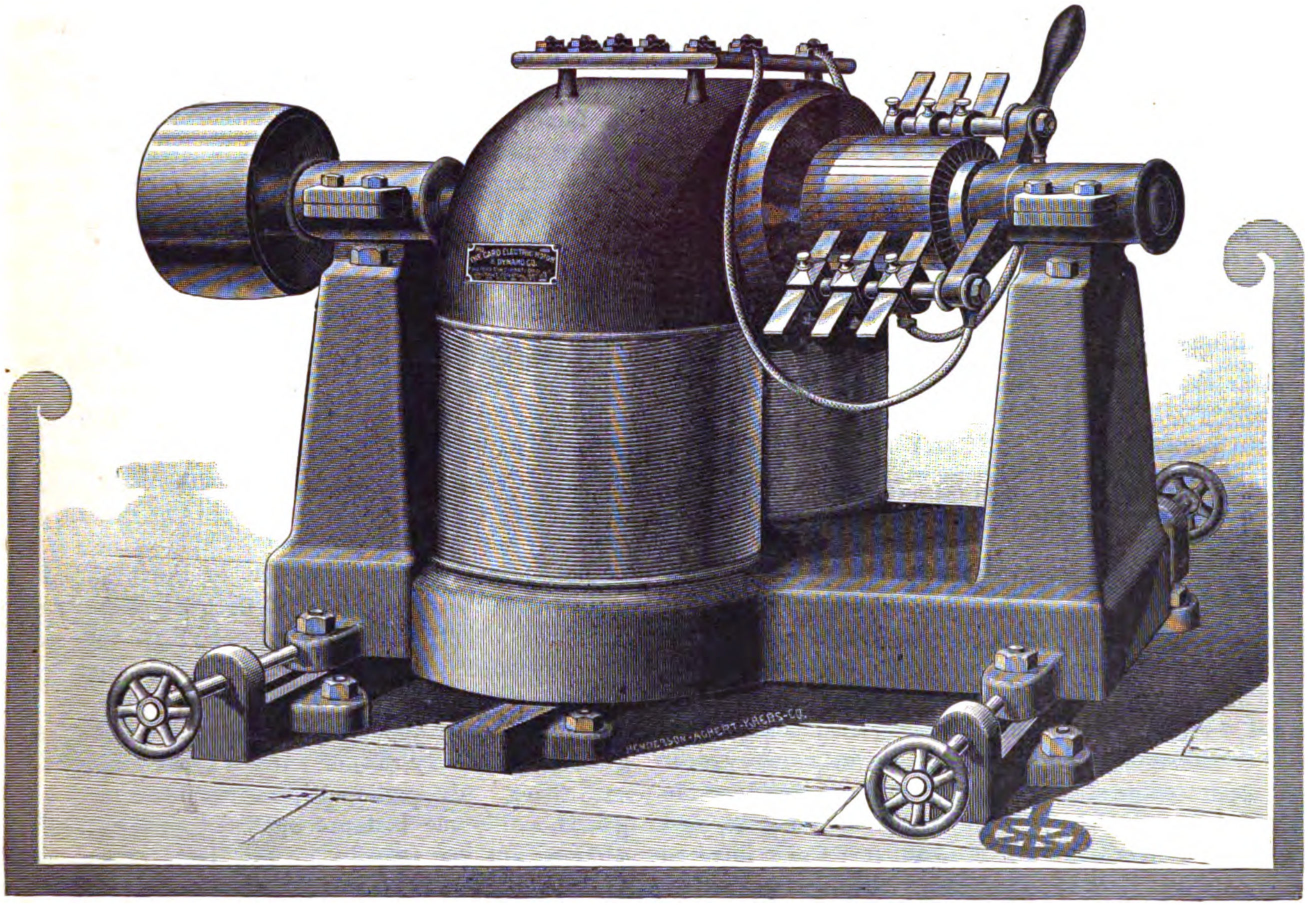
ELECTRICITY IN SINGAPORE.

A reader of The Electrical Engineer at Singapore, Strait's Settlements, India, writes us of the paper: "It is an old friend and finds a generous welcome. Electric lighting has found its way into Singapore and illuminates the Government house. I see no reason why American plants should not find a ready market on the Asiatic coast."

THE NEW CARD ELECTRIC MOTOR AND DYNAMO.

Among the machines recently brought out and designed both as a motor and dynamo is that of the Card Electric Motor and Dynamo Co., of Cincinnati, O., and which is illustrated in the accompanying engraving.

This type of machine has been adopted by the company for all their motors above 8 h. p., and incandescent dynamos from 100 to 400 lights. The motor, as shown, is very simple and compact, occupying very little space in proportion to the power produced. The fields and pole-pieces are of one solid wrought iron forging. These fields are set into a cast-iron base, which, with the end bearings, form one solid casting. The bearings are self-oiling, and have an interchangeable phosphor bronze sleeve, thus making the motor a very durable, economical and efficient machine.



HENDERSON-ACHERT-KREBS-CO.

The New "Card" Motor and Dynamo.

SELENIUM CELLS USED FOR COMMERCIAL PURPOSES.

Mr. Shelford Bidwell, at the end of an interesting paper read at the Physical Society, showed a selenium cell controlling a relay which served several purposes. For instance, there was an arrangement of a selenium cell which turned on a little lamp on the approach of darkness, and turned it out when daylight reappeared. Another arrangement of the cell served the purpose of giving notice if a burglar showed a light anywhere in its neighborhood. To avoid this result, a scientific burglar will, perhaps, be provided in future with a yellow glass in his "dark lantern." The cell could also be used to give notice if a railway signal lamp or ship's side lights should be extinguished. The arrangement has also useful applications as a fire alarm.

AN ILLUSTRATION OF EWING'S THEORY OF MAGNETISM.

BY PROF. S. P. THOMPSON, D.SC.

A number of small "charm" compasses were placed together on a glass plate of an ordinary vertical attachment to a lantern. A large magnet at a distance served to neutralize the earth's field, and a coil enabled a magnetizing force to be applied in the plane of the needles. By this apparatus all the various phenomena exhibited by Ewing's model were beautifully shown on a screen. In the course of his experiments Dr. Thompson had found that when small magnets, placed at moderate distances apart, were used it was much more necessary to neutralize the earth's field, in order that they might set themselves according to their mutual attractions, than when larger magnets were employed. A weak field directed the small openly spaced magnets, whereas with larger ones their mutual actions were much more powerful. This fact may, he thought, throw some light on the molecular groupings in magnetite (loadstone). This substance exists in two forms, one crystalline and the other of a heterogeneous structure. The former variety exhibits no magnetic retentiveness, whilst the latter is decidedly magnetic. As far as he was aware, no sufficient explanation had been given of the non-retentiveness of the crystalline variety. A difference in the molecular distances or grouping might account for the peculiarity. Mr. Boys said it was rather curious that Prof. Rucker had just devised a somewhat similar illustration of Ewing's theory, and he exhibited it at the meeting. It consists of little magnets made of long U-shaped pieces of watch-spring, pivoted by glass caps on needle-points; the needle-points are fixed in little discs of lead stuck on a sheet of glass, which forms the base of a glass box. An open helix surrounding the box serves to apply magnetic force.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* The Electrical Engineer. *Communications for the attention of the editors should be addressed,* Editor of The Electrical Engineer, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

Vol. XI. NEW YORK, JANUARY 7, 1891. No. 140

The subjugation of electricity to the mechanical necessities of man will mark the last era in human civilization.—John C. Calhoun.

FIFTY YEARS OF INDUSTRIAL ELECTRICITY.

THE fact that the year which has just closed was the jubilee or semi-centenary year of the electric motor, considered in its industrial aspect, appears to have entirely escaped the attention of our chroniclers. The history of the early attempts in this country to evolve motive power from electro-magnetism has hitherto been involved in no little obscurity. Beyond the tradition—which we find occasionally referred to—that a newspaper was printed in the city of New York in 1840, upon a press driven by electro-magnetism, and some meagre and unsatisfactory accounts of the experiments made by Page, under the patronage of the government some ten years later, the American annals of electric power up to within a few years are little better than a blank.

It seems peculiarly appropriate, at the beginning of the second half-century of the industrial career of electro-magnetism as a motive power, that the history of its infancy and childhood should be revised and rewritten by a competent and unprejudiced pen. At an earlier date indeed it would scarcely have been possible to justly weigh and apportion the merit of the work of the pioneers and to rightly comprehend its actual relation to the perfected state of the art as it exists to-day. We feel therefore a peculiar satisfaction in announcing that this work has been undertaken by Mr. Pope, in the series of papers of which the first instalment is given in the present issue of The Electrical Engineer, and when we state that he has had access to numerous family letters, papers and other contemporaneous manuscripts never before published ; that he has personally visited, sketch-book and camera in hand, the scenes of the labors of the early experimenters ; that he has conversed with surviving eye-witnesses, and ransacked the files of the publications and pamphlets of half a century ago, and moreover that he brings to the work the experience of a trained expert in patent law, and the skill of a practical writer, we think we may promise our readers a series of papers the immediate interest of which will only be equaled by their permanent historical value. The researches of Mr. Pope appear to establish beyond peradventure, the fact that the typical motor of to-day is in all its essentials a machine of independent American origin, and we feel well assured that the hitherto undiscovered evidence which he presents in support of this claim, cannot but prove of unexampled interest to electricians on both sides of the Atlantic. Mr. Pope's work supplies, in the most satisfactory manner, what has hitherto been regarded as the one missing chapter in the annals of electro-magnetism, and we congratulate our readers and ourselves upon the good fortune and success which has attended him in his interesting researches.

SLOW SPEED STREET CAR MOTORS.

The tendency to the reduction in speed of motors used in street railway service is becoming more and more marked as time passes, and as the benefits which the application of such machines confer upon the operation of the street car become recognized. From the early methods of the belt and sprocket wheel and chain the system changed gradually to that of spur gearing, which is now generally employed, but which on account of the high speed had required two pairs of gears to effect the proper reduction at the car wheel. Recently, also, no little ingenuity has been expended in devising methods of gearing by which the motor might be kept in continuous operation and its motion gradually applied to the car axle in starting, thus avoiding the heavy rush of current usually experienced at such times. Although multipolar machines have been suggested, and in one instance applied to railway work, the arrangement we describe in this issue and due to Mr. William Baxter, Jr., is worthy of notice as it is the first instance of the application of a machine having as many as eight poles. The design of such a machine to fit under a car without necessitating the raising of the platform above its usual height and still leaving a clearance sufficient to avoid all contact with possible obstruction along the track, will be conceded to be a problem of no small difficulty, but the results which have been accomplished, as exhibited in the recent trials which we had the pleasure of attending, leave no doubt in our minds that the arrangement adopted is a perfectly practical and successful one. The gearing of the motor shaft directly to the axle of the car, doing away as it does with the use of an intermediate pair of gears, necessarily avoids considerable friction and loss of power. It is obvious that by the employment of an armature of large diameter subjected to the induction of a multipolar field, the large torque exerted effects a rapid starting of the car and the counter E. M. F. quickly generated by but a small motion of the armature tends to cut down almost entirely the sudden rush of current which is observed when two-pole machines are employed in such service. The mechanical arrangements embodied by Mr. Baxter in his new design are also worthy of attention as removing some of the difficulties which have been experienced in the past in railway work.

ELECTRIC LIGHTING IN LONDON.

After a long period of apathy and inaction, not due to any lack of ambition on their part, but to the restrictions placed upon them, the local electric lighting interests of London are genuinely aroused, and, in spite of the temporary financial depression, one hears of an immense amount of new work being done there. The actual status of electric lighting in the British metropolis is well brought out in the figures of Mr. Bailey, given before the English Society of Arts, and effectively summarized by our London correspondent. It will be seen that Mr. Bailey, who is in a position to know, figures out a total of no fewer than 264,000 incandescent lamps of 32 watts each, in London. The present rate of increase is given as 4,000 per week, so that the total may be doubled within another year. It was also stated in the subsequent discussion that the total for London was twice as large as for New York. This is a mistake. Although no recent statistics have been taken here, the figures for both cities are pretty nearly the same, favoring New York, and there is, moreover, an additional 10,000 h. p. of arc lighting in New York. Besides, the comparison even then is not a correct one, as London is a city at least three times as large as New York. However, be that as it may, our London friends cannot be congratulated too warmly on the magnificent showing they make. It has been reached across greater obstacles than we have had to contend with in America, and though they do not yet run stations as well as we do they certainly put more money and pains into their construction work. The results attested to by Mr. Bailey are most gratifying to all who are working for the ultimate supremacy of the electric light in the field of artificial illumination.

Storage Battery Analysis.

The work of Gladstone and Tribe on the chemical actions taking place in the operation of the storage battery, has, with but few additions, such as those of Frankland, been the chief source of our information and has helped to a considerable extent in eliminating some of the early difficulties. At the meeting of the London Institution of Electrical Engineers, at Edinburgh, early in the past year, Prof. Ayrton and his associates embodied in an admirable paper the results of a series of tests which are now supplemented by another paper of which we give an abstract. The two papers taken together have given us the results of what is unquestionably the most extended series of tests thus far undertaken in storage battery work, and the conclusions derived from them throw much light on disputed points. The variations in the composition of the active material on the positive plate, as charge and discharge proceed, both as to its general character and the differences existing in various parts of the same plate, prove that much can still be done to obtain higher efficiency and uniformity in storage battery electrodes.

A Floating Magnet.

Floating magnets, consisting of steel pieces mounted upon cork, constitute one of the oldest forms of classroom experimental apparatus, but a decided novelty, in more senses than one, is the floating magnet devised by Prof. Dolbear, which he describes in another column. The experiment serves not only to demonstrate the presence and directive action of the earth's magnetism, but gives also an ocular demonstration of the magnetic lines of force. In addition to this, it demonstrates the property of magnetic retentivity and the molecular structure of a magnet, as brought out in Ewing's recent theory. It would, indeed, seem difficult to devise a single arrangement embodying more of the principles and phenomena of magnetic action than this simple and beautiful experiment. Its ready adaptability to demonstration before large audiences, also, is not the least among its merits.

The Deadly Christmas Tree.

During the past week the papers have teemed with accounts of accidents and deaths from Christmas tree fires, and as this cannot be endured in a civilized community, a movement has been started, we are glad to say, to suppress the deadly thing. It is proposed to establish a Board of Christmas Tree Control, one of whose duties it will be to see that none but incandescent lamps are used on the trees hereafter, and who will prepare rules and regulations for their enjoyment. It has been objected in one or two quarters that during 11½ months of the year, the Board will have nothing to do, but while this criticism is laughed at by the city authorities, as puerile, it is seriously suggested that the inspectors of the Board can employ their leisure and greatly lessen the loss of life and injury to limb of the citizens by being also given jurisdiction over orange and banana peels if thrown on the sidewalks. One of the papers that has been very outspoken in its opposition to the electrical execution law, has hastened to improve the occasion and the prevailing sentiment by proposing that condemned murderers shall be given candle-lighted Christmas trees to play with. The suggestion is not without its merit, as the criminals would thus pass to their doom while in the pleasant state of exhilaration that arises from participation in innocent pleasures.

Automatic Electric Light Switches.

It was long ago told of Mr. Edison that in starting out to produce successful commercial incandescent lighting he set himself the problem of creating a system which should in every way be able to replace gas. But one of the devices which has been employed in gas lighting seems thus far to have been neglected in electric lighting. We refer to the very convenient automatic burners which are operated by push buttons placed in any convenient position. It is obvious that an automatic switch similarly operated from a distance to effect the turning on and extinction of lamps must find a large number of applications, and the device for this purpose which we describe in another column will therefore be read with considerable interest. It is true that the switch generally employed to control any light may be placed in any convenient position, but the loss in wire entailed in the detour usually necessary, makes a device by which this inconvenience is obviated, one of considerable value and convenience.

ROWLAND AND DUNCAN'S SYSTEM OF STORAGE BATTERY DISTRIBUTION.

Of the various methods for effecting the distribution of current with economy in conductors that involving the employment of storage batteries, though presenting not a few advantages, has not received the attention which the merits of the system would seem to deserve. It is evident that storage batteries can be located at a distance from a central station and charged in series with a high tension current transmitted over a small conductor, and discharged in parallel at low tension to the surrounding district.

A method of accomplishing this transformation by means of a commutator has recently been designed by Prof. Henry A. Rowland and Dr. Louis Duncan, of Johns Hopkins University, Baltimore. In this system the commutator and the shifting connections are so arranged that neither the charging nor the discharging circuit is ever broken at any time, but both are always continuous.

The manner in which this is carried out is illustrated in the accompanying engravings, Fig. 1 showing a diagram of the circuits with the commutator-cylinder developed as a flat surface, and Fig. 2 a view in elevation of the commutator with a diagram of the circuits.

As will be seen, the high tension dynamo D at the central station is connected by wires *a a* with the commutator G at the distributing station. The commutator of the tension-reducer consists of a cylinder of insulating material and carrying metal contact strips on its surface, upon which bear the contact brushes, numbered from 1 to 24.

A B C each represent one of the sets of secondary batteries. The cylinder is rotated rapidly by an electric motor H which receives current from either the high tension or low tension circuit.

The contact-strips on the cylinder are divided into sets, there being two sets of strips for each set of secondary batteries—one set for charging and the other for discharging. The strips marked *c*, *c'* and c^2 are for charging and are connected in series. The strips *d d'* and d^2 are for discharging and are connected in multiple.

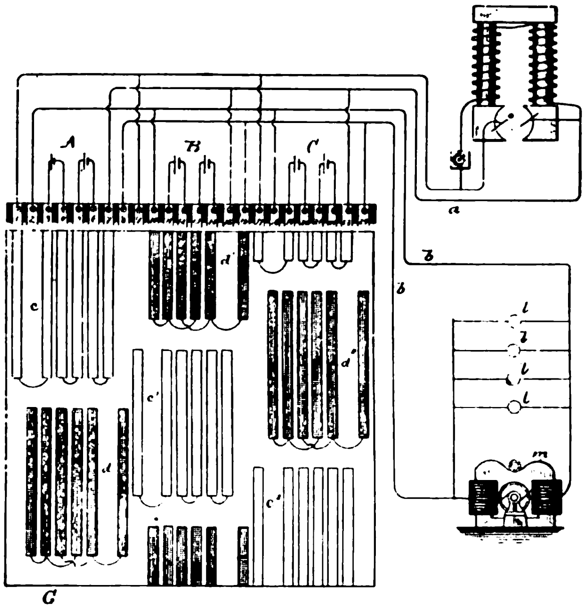

Fig. 1.—Rowland and Duncan's System of Current Distribution.

When the parts are in the position indicated in Fig. 1, it will be seen that the batteries A are connected in series with the charging-circuit by means of the springs bearing on the strips *c*. The batteries C are also connected in series with the charging-circuit by means of the springs bearing on strips c^2. The batteries B are, however, connected in multiple arc with the discharging-circuit by means of the springs which bear on the contact-strips *d'*. It will thus be seen that while the batteries receive a current of high-tension from the charging-circuit they discharge a current of low tension on the consumption-circuit, in which circuit the incandescent electric lamps *l*, electric motors *m*, etc., are placed. When the commutator cylinder revolves, so that the springs leave the strips c^2, the batteries A will still be charging in series while the batteries B are still discharging in multiple arc. The springs will reach the strips d^2 before they leave *d'*, so that for a moment batteries B and C will both be discharged in multiple arc while batteries A are still charging in series, after which the springs will leave strips *d'* and momentarily C will be alone discharging while A is still charging. It will thus be seen that one or more sets of batteries are always in connection with the charging-circuit and one or more sets always in connection with the discharging-circuit, so that neither of these circuits is ever broken.

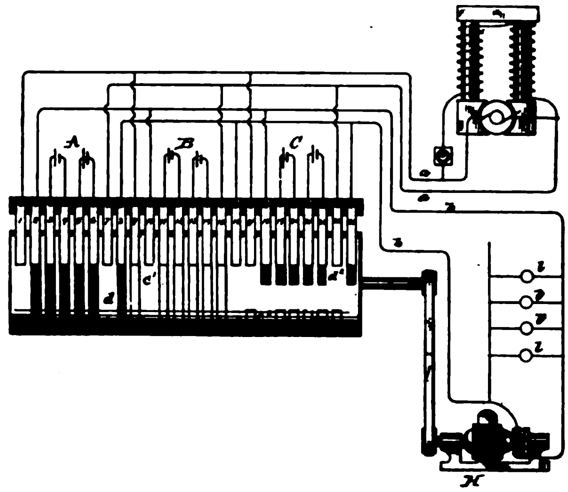

Fig. 2.—Rowland and Duncan's System of Current Distribution.

ON ALTERNATE CURRENT CONDENSERS.[1]

BY JAMES SWINBURNE.

It is, he said, generally assumed that there is no difficulty in making commercial condensers for high pressure alternating currents. The first difficulty is insulation, for the dielectric must be very thin else the volume of the condenser is too great. Some dielectrics 0.2mm. thick can be made to stand up to 8,000 volts when in small pieces, but in complete condensers a much greater margin must be allowed. Another difficulty arises from absorption, and whenever this occurs the apparent capacity is greater than the calculated. Supposing the fibres of paper in a paper condenser to be conductors embedded in insulating hydrocarbon, then every time the condenser is charged the fibres have their ends at different potentials, and a current passes to equalize them, and energy is lost. This current increases the capacity. One condenser made of paper boiled in ozokerite took an abnormally large current, and heated rapidly. At a high temperature it gave off water, and the power so wasted and current taken gradually decreased.

When a thin plate of mica is put between tin foils, it heats excessively, and the fall of potential over the air films separating the mica and foil is great enough to cause disruptive discharge to the surface of the mica. There appears to be a luminous layer of minute sparks under the foils, and there is a strong smell of ozone.

In a dielectric which heats there may be three kinds of conduction, viz., metallic, when an ordinary conductor is embedded in an insulator; disruptive, as probably occurs in the case or mica, and electrolytic, which might occur in glass. In a transparent dielectric the conduction must be either electrolytic or disruptive, otherwise light vibrations would be damped.

---

[1] Abstract of a paper read before the London Physical Society.

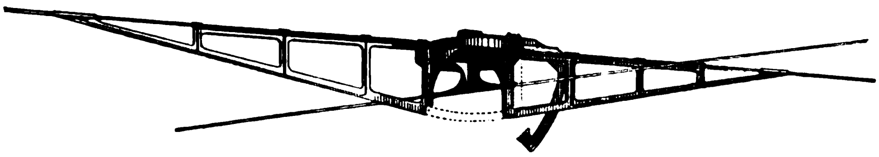
The dielectric loss in a cable may be serious. Calculating from the waste in a condenser made of paper soaked in hot ozokerite, the loss in one of the Deptford mains came out 7,000 watts. Another effect observed at Deptford is a rise of pressure in the mains.

There is, as yet, no authoritative statement as to exactly what happens, and it is generally assumed that the effect depends on the relation of capacity to self-induction, and is a sort of resonator action. This would need a large self-induction, and a small change of speed would stop the effect. The following explanation is suggested. When a condenser is put on a dynamo the condenser current leads relatively to the electromotive force, and therefore strengthens the field magnets and increases the pressure. In order to test this the following experiment was made for the author by Mr. W. F. Bourne. A Gramme alternator was coupled to the low pressure coil of a transformer and a hot-wire voltmeter put across the primary circuit. On putting a condenser on the high pressure circuit the voltmeter wire fused. The possibility of making an alternator excite itself like a series machine, by putting a condenser on it, is pointed out.

THE BAGNALL LIVE TROLLEY CROSSING.

In the erection of overhead trolley wires where the tracks of one company cross the tracks of another, the company first to erect their trolley line will obviously have the right to the most favorable position, that is, the under position. The company last on the ground are required to take the upper position. Their cars are therefore left without current while passing the crossing. The current must be shut off from the motor before reaching the crossing so as to avoid arcing at the crossing gap.

The Bagnall live trolley crossing is designed to avoid this difficulty and maintain continuity of the current to the trolley arm while passing such a crossing. The cut herewith shows a perspective view of the device. To the upper trolley wire is attached a bridge-piece of light lattice casting, at the centre of which is a gap through which the under trolley wire passes. It is attached to, but insulated from, the bridge by means of a disc of insulating material placed in an inverted cup at the centre of the bridge. A curved lever hinged to the upper side of the insulator cup rests by the action of gravity in the position shown in the cut. The passage of a trolley wheel along the wire from right to left will carry the lever along with it and thus bridge over the gap as shown by the dotted ines and thus maintain a continuous connection between he upper trolley wire and the trolley wheel. After the rolley wheel has passed over the gap, the lever is released nd falls by gravity into its former position of rest. The inge and guides of the lever are protected by a hood—not hown in the cut—as a protection against ice.



Bagnall Live Trolley Crossing For Electric Roads.

In fixing this crossing in position it is not necessary to ut either of the trolley wires. It is attached directly to he upper trolley wire by means of clips and solder, and e under trolley wire is attached in the same way to its sulator web. In case of slackening or changing in position the trolley wires, the clips can be unsoldered, and the idge moved along in the direction necessary to secure the readjustment, and then soldered again. This ingenious device is being manufactured by the Emerson Electrical Manufacturing Co., of St. Louis.

THE BERGMANN AMMETER.

It has long been recognized that for the proper operation of electric lights circuits, whether arc or incandescent, an ammeter to measure the strength of the current is indispensable, and in order to obtain a form which, while simple and accurate, shall at the same time be reliable and easily read, the Bergmann Electric & Gas Fixture Co. have recently brought out the instrument illustrated in the accompanying engraving. As will be seen, the instrument consists of a solenoid magnet, the core of which acts directly upon a peculiarly shaped armature. The latter consists of a curved and tapered piece of sheet iron, which is mounted on a brass sector, pivoted so as to swing freely. This arrangement is so constituted that the deflections of the armature are practically proportional to the strength of the current and hence equally spaced over the entire range of the scale. Another remarkable feature, which we have had occasion to notice in a test of the instrument, is its remarkable dead-beat quality. This becomes apparent when we consider the fact that the armature is brought in the closest possible contact with the exciting magnet core. For this reason, therefore, the instrument is admirably adapted for portable use, as well as in ship lighting, which requires an instrument which shall not be seriously disturbed by the movements of the vessel. The ammeter is built in sizes ranging from the smallest to the heaviest capacity.

MUNICIPAL OWNERSHIP OF GAS WORKS IN THE UNITED STATES.[1]

BY PROF. EDWARD W. BEMIS, OF VANDERBILT UNIVERSITY.

Of the nine cities that now own and operate their gas works in this country, one, Hamilton, Ohio, a city of 20,000 inhabitants, has begun too recently to enable results to be given. The other eight, Philadelphia, Wheeling, W. Va., Bellefontaine, O., Henderson, Ky., and four cities in Virginia—Richmond, Danville, Charlottesville and Alexandria—after a fair trial of many years, have recently refused to entertain good offers from private companies to take the works off their hands. There is most dispute about Philadelphia, which began ownership in 1841, and most foolishly placed the entire control of the works till 1885 in the hands of a self-perpetuating body of trustees; who, being free from responsibility to the people, a primary principle of public finance, naturally abused their powers and became a corrupt body. The bad results finally led to the overthrow of the trust in 1885, and the restoration of the works to public control. Since then, the city management has steadily improved, until in 1889 the cost of over three billion feet of gas, 20 candle power, was only 74 cents per 1000 feet, no allowance being made for interest and the taxes which a private company would have to pay. Allowing five per cent. interest and two per cent. taxes on the cost of duplicating the works, very high figures, the cost of gas would be only $1.02. The city buys some water gas of a private company, but could make it nearly as cheaply if allowed by the legislature to raise money for constructing the proper works.

Richmond, Va., with a population of 87,000, manufactures gas at 76 cents a thousand feet. An allowance of six per cent. for interest and two per cent. for taxes, would raise the cost to only $\$1.04\frac{1}{4}$.

Wheeling, W. Va., with a population of 43,000, does the best of all the cities owning their gas works. Its output of 115,000,000 feet at the burner costs but $43\frac{7}{10}$ and is sold for 75 cents. A liberal allowance for interest and taxes would raise the cost to only 70 cents. Wheeling secures her coal for about 17 cents per thousand feet of gas in the burner. Most other cities in the East have to pay about 20 cents more for coal, but by-products are very low in Wheeling.

In none of the other five cities does the population exceed 15,000, and so the cost of gas is higher; for the cost of gas-making rapidly falls, at least up to 100,000,000 feet a year, with increase in consumption. But all of these cities have done very well. The cost of making, even with allowance for interest and taxes, exceeds $1.33 only in the case of Danville, Va., where coal is five dollars a ton, or over 55 cents a thousand feet of gas in the burner.

In most of the cities owning their own works, slightly higher wages are paid for common labor than in private-owned works, which some may consider a good thing; and there is a tendency toward employing members of the dominant political party. But this has rarely gone so far, especially in recent years, as to affect the positions of superintendents and other skilled officers. The superintendent in Richmond since 1886, was assistant-superintendent for the previous 16 years. The superintendent in Danville has had his office for 16 years; in Henderson, since the city took charge in 1882; in Charlottesville since 1855. In Alexandria, the superintendent now in charge has been out of office only two years in eighteen. Yet, in all these places there have been occasional changes of the party in power.

A study of those fairly representative cities proves the contention of Professor James and others, that in the cities exceeding 10,000 inhabitants, the cost of the entire plant is less than six dollars for every thousand feet sold during the year, and from three dollars to five in most cities of over 50,000. The capitalization much in excess of this common in American cities, and sometimes two to four-fold on which dividends are paid, reveals the monopoly profits of private-owned gas works.

MR. BARTON AND THE "CHRONICLE FIRE TABLES."

Mr. S. E. Barton, president of the Electric Mutual Insurance Co., of Boston, has lately, with very good reason, found fault with the "Chronicle Fire Tables" because they included in electrical fire losses of 1889 the loss due to the big fire in Boston. That fire has not yet been proved in any way to be due to electricity, and as the loss there constitutes 70 per cent. of the alleged electrical fire losses. Mr. Barton is simply discharging a public duty in protesting. He has not received much courtesy at the hands of the "Chronicle," but his last letter on the subject, with a copy of which he favors us, shows he is holding his own gallantly. He has our warmest sympathy in his fight, which aims only to remove from electric lighting a stigma it has not been shown to deserve.

THE SOCIAL SIGNIFICANCE OF STREET RAILWAYS.[1]

BY CHARLES H. COOLEY.

At the fourth annual meeting of the American Economic Association at Washington, December 26-30, a paper upon the above subject was read by Charles H. Cooley, of the U. S. Census Transportation Department. "Rapid transit," said the author, "has hitherto been discussed by economists chiefly in connection with other questions, and therefore in a somewhat desultory and one-sided manner. There is need that street railway transportation should be studied apart from those questions with which it is usually connected, and that an attempt should be made to gain a more adequate and scientific conception of its social functions. This subject will be considered under three heads: (1) It will be attempted to formulate a more comprehensive conception of the function of city transportation; (2) The increasing need of the effective performance of this function will be shown; (3) Various factors upon which efficiency depends will be discussed.

We must recognize in the system of urban transportation a definite social organ having for its function a distribution of population about industrial centres. It is an industrial necessity that men shall work in dense aggregates, while humanity requires that they shall not so live.

The conditions of industrial life are such that the number of aggregate workers necessarily increases relatively to the number of scattered workers. There is, too, a conflict between the industrial tendency to aggregation and the needs of humanity. The function of city railways is to reconcile these conflicting requirements of the social organism. When the social function of rapid transit is clearly conceived, the importance of the efficient performance of that function readily appears. The nearer a condition of ideal efficiency is approached the more possible is it to secure to the poorest classes the conditions of healthful and moral living by increasing the extent to which a given industrial population may be spread out. On account of the rapidly increasing aggregation of population, the need for efficient rapid transit must constantly increase. Two of the factors which enter into the efficiency of city transportation may profitably be considered without the necessity of entering into technical discussion. These factors are the speed of the cars, and the cost of riding. It is found that the distance from their work at which it is possible for those to live who ride to and fro on the cars varies directly with the speed of the cars, but the total area which rapid transit makes available for population varies as the square of the speed of the car. The cost of riding is a very important factor of efficiency because every decrease in fares brings suburban residence within reach of larger classes of the poorest people. A phenomenon which, though incidental to the spreading of population, is yet of first importance, is the influence of rapid transit on city rents. In some cases an actual decrease of rent in thickly settled quarters has been observed to follow the opening of a new suburban railway. It was hardly too much to say that the introduction of electric traction would double the speed and halve the expense of street railways. Although barely three years had elapsed since its practicability for this work was generally admitted, the development since that time had not been equalled in any other industrial branch. He believed there was no engineer who did not look forward to an increase in the effectiveness of all the factors of urban transportation. The influence of a reduction in fares was shown by reference to the experience of the New York elevated railroads where a reduction from an average of $6\frac{3}{8}$ to 5 cents led to an increase of 35,000,000 passengers above the normal increase of 9,000,000 yearly. Rapid transit must not be regarded too exclusively as a source of municipal revenue. The function of spreading population is of co-ordinate importance with any of those now performed by the administrative agencies of cities. Should street railways ever be owned or directly controlled by the public, cheapness and efficiency of service should be considered as of more moment than the obtaining of municipal revenue.

THE NEW TELEPHONE EXCHANGE FOR ALBANY, N. Y.

The Hudson River Telephone Company, it is said, will spend about $200,000 for general improvements to its plant. Its new fire-proof building will be erected at the northeast corner of Maiden Lane and Chapel street. The new structure will have a frontage of 85 feet on Maiden Lane and 23 on Chapel street, will be three stories in height and cost $40,000. On the first floor on Maiden Lane will be the messenger service rooms and the linemen's quarters. On the principal floor, on Chapel street, will be the offices of the manager, assistant manager, bookkeeper and cashier On the second floor will be the operating room, the offices of the president, vice-president and the directors; and on the third will be the necessary appliances for the distribution of the wires, the battery room, etc.

NOTES ON THE CHEMISTRY OF SECONDARY CELLS.[1]

BY PROFESSOR W. E. AYRTON, VICE-PRESIDENT; C. G. LAMB, B.SC., AND E. W. SMITH, ASSOCIATES.

In our paper on "The Working Efficiency of Secondary Cells," read at the meeting of this Institution in Edinburgh in July, it was stated that, "In spite of accumulators with pasted plates having been in use now for nine years, the chemical action that takes place during the different stages of the charge and discharge has only been conjectured, and, odd as it seems, no decisive experiment appears to have been made to settle this much-debated question. Various analyses have been made by different chemists of salts of lead acted on in certain ways with sulphuric acid, but apparently not of actual accumulator plates in action. We are therefore now, with the assistance of Mr. Robertson, making a complete investigation of the chemical state of the plugs of both the positive and negative plates at all stages of the charge and discharge of an 1888 E. P. S. type of accumulator in good condition." The present paper contains an account of the results thus obtained.

The cell selected to remove the plugs from had the same size as the cells employed in the investigations described in the previous communication, and was one of the batch of 50 purchased for the Central Institution about the middle of 1888. Since it first came into our possession it had never been overcharged, never been left discharged, nor permitted to send more than the maximum current allowed by the makers for cells of this size—viz., 10 amperes—and consequently, at the beginning of the present investigation in June of this year, this cell was in excellent condition.

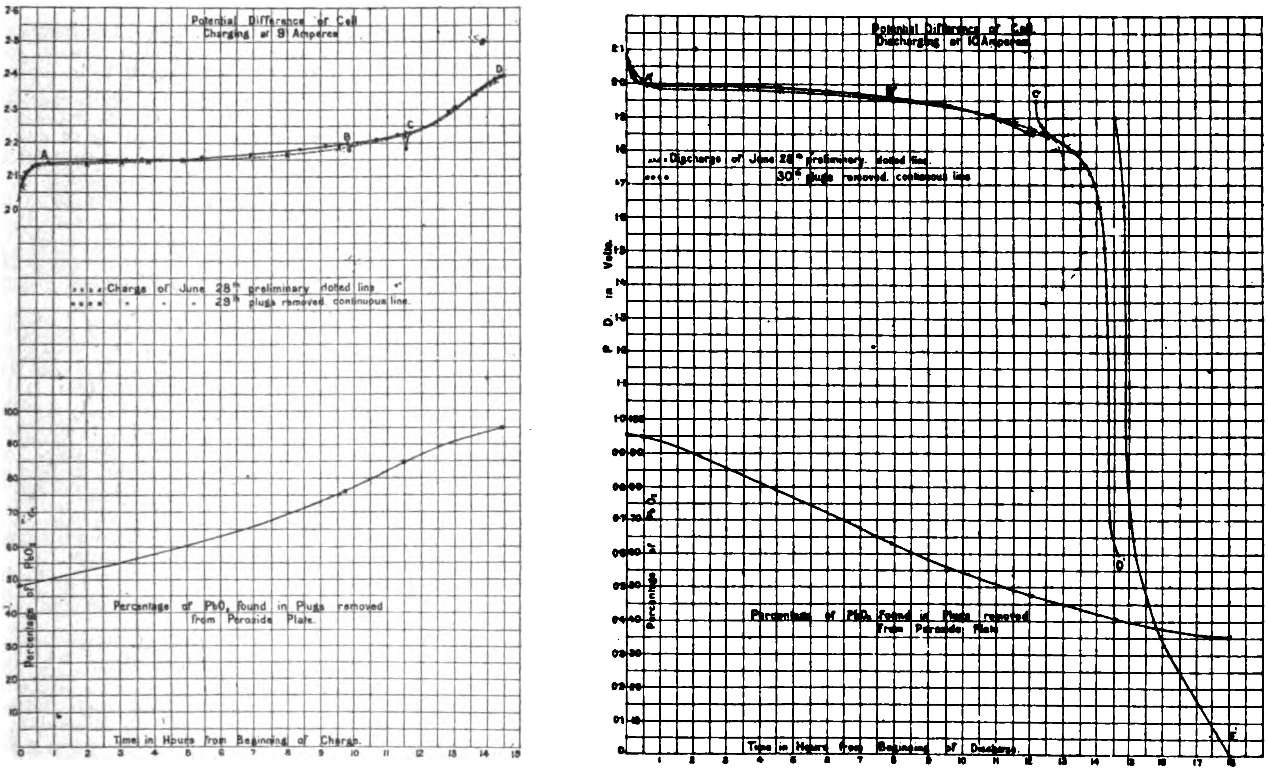
First the cell was several times charged with a current of 9 amperes, and discharged with a current of 10, without stopping day or night, so as to bring it into what we have called its steady "working" state. The dotted curves, Figs. 1 and 2, show the large charge and discharge obtained on June 28th. During the next charge, indicated by the continuous curve, Fig. 1, plugs were removed from both the positive and the negative plates at the points marked *A, B, C* and *D*, when the terminal P. D. of the cell was 2.134, 2.2, 2.284, and 2.4 volts respectively.

After the cell had been charged until the terminal P. D. reached 2.4 volts, it was immediately discharged with a perfectly constant current of 10 amperes, and, as it was anticipated that the removal of the plugs would spoil the cell, it was allowed to discharge far below the normal limit. In previous discharges (the last one of which is shown by the dotted line, Fig. 2), the discharge was stopped when the terminal P. D. fell to 1.85 volts. But in the discharge on June 30th, when the plugs were removed the discharge current was kept at 10 amperes, by using auxiliary cells, until the E. M. F. of the test cell fell to nought, and even reversed. Plugs were removed from both the positive and the negative plates when the terminal P. D. was 2, 1.95, 1.85, 0.6, and nought volts, as indicated by the points *A′, B′, C′, D′*, and *E′*. The recovery of the E. M. F. on breaking the circuit was very marked, especially near the end of the discharge.

The plugs from the top, the middle, and the bottom of each set of plates were at each of the removals of plugs put into six separate bottles, and, to avoid the possibility of error in their subsequent identification, there was noted on the label of each the character of the plates and the position on them from which the plugs were removed, the time, the P. D., and the specific gravity of the liquid in the cell.

Figs. 3 and 4 give an idea of the way in which we found the hardness of the top and the bottom plugs of the positive and the negative plates respectively to vary during a normal charge. The figures are not drawn to scale, as we had no standard of hardness beyond our sensations, hence the figures only profess to be qualitative sketches from which mental pictures can be obtained. Distance measured upways from *O A* indicates roughly the degree of hardness; distance measured downwards the degree of softness.

It will be seen that during the charging the variation in the hardness of the plugs is far greater at the top than at the bottom of the plates, and consistently with this fact Mr. Robertson's analyses show that, on the whole, the rate of chemical action at the top of the plates is greater than at the bottom. The difference in the hardness, however, is far more marked than the difference in the chemical action. For example, while the plugs at the top, on the positive plates are, during the earlier part of the charging, much harder than those at the bottom, no such striking difference is observable in the percentage of lead peroxide contained by these plugs. The cause of this we are examining experimentally at the present time.



FIGS. 1 AND 2.—CHARGE AND DISCHARGE CURVES, STORAGE BATTERY TESTS.

In order to see how far the resistance of the lead grid would tend to make the current-density in the upper part of the liquid less than in the lower, as well as for the purpose of seeing how large a fraction of the whole resistance of the accumulators was due to the lead lugs and to the connections between the successive pairs of lugs, various tests were made from which it appears that the resistance per inch of the lug alone is about 0.000043 ohm: and that the resistance at the contact of two lugs which were tightly screwed together when quite clean, but which have become very dirty from the acid spray falling on them, may be as high as 0.01 ohm, or thirty times the resistance of an inch of the lug itself.

As we have shown in the Edinburgh paper, the mean resistance from positive lug to negative lug of one of these accumulators *complete* is about 0.004 ohm when the contacts between the lugs and the testing wires are made quite clean. Hence it appears that about one-seventh of the whole mean resistance of such an accumulator is caused by the resistance of the lead lugs themselves; and that the resistance of such accumulators as we have been experimenting with can, when joined up in series, be increased by 25 per cent. if the contacts be allowed to become dirty by the acid spray falling on them, even although they remain all tightly screwed up.

---

[1] Abstract of a paper read before the Institution of Electrical Engineers.

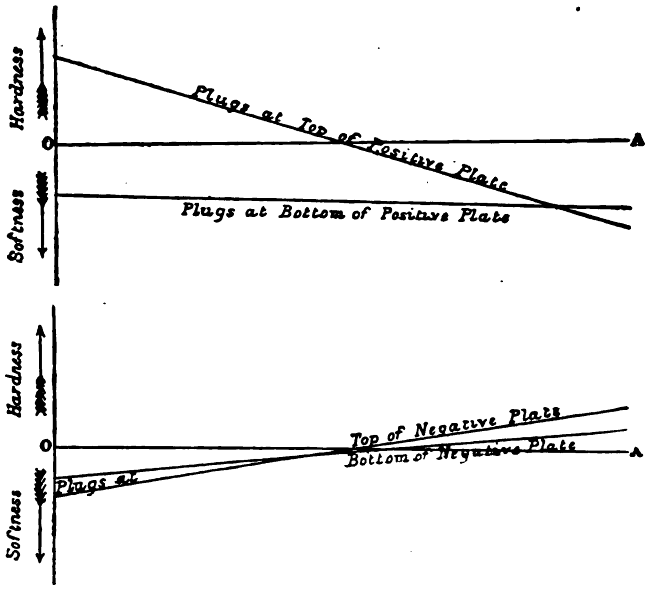
From the mean results of the chemical analysis carried out by Mr. Robertson, we have drawn the curves seen in the lower part of Figs. 1 and 2, and which show the percentage of $Pb\,O_2$ found in the plugs of the positive plate at all stages of the charge and discharge. In the $Pb\,O_2$ curve for charge the first point is obtained from the analysis of the plugs at the end of the normal discharge—that is, when the terminal P. D. had fallen to 1.85 volt, indicated by the point C' in Fig. 2.

The screening influence of lead sulphate is clearly brought out in this curve. Between A and B the surface film and the coatings on the partially reduced granules of $Pb\,O_2$ are got rid of; then between B and C the pure lead sulphate is attacked; and finally, between C and D, with the removal of the last traces we get a very rapid rise in volts P. D.

It was observed that:—

(*a*.) The particles of the peroxide very soon get coated in the discharge with a layer of lead sulphate, which protects the peroxide from further action, as shown by the examination of the dark colored residues which contained peroxide, and which were rendered very hard to dissolve by the coating of sulphate.

(*b*.) The analysis also shows what a large proportion of active material is still remaining at the end of the discharge. This has been remarked on by many experimenters.



FIGS. 3 AND 4.

(*c*.) The loose powdery surface of the positive plate seems to be thoroughly converted into lead sulphate.

(*d*.) When the peroxide in the surface of the plate falls to about 31 per cent. the cell loses its its E. M. F. very rapidly, owing to the inactive layer of sulphate impeding the action of the sulphuric acid on the active material behind it, and also to the formation of peroxide on the negatives. The diffusivity of the acid is decreasing, and it has to penetrate further into the plate to find active material. When the whole of the paste approaches this composition of 31 per cent. peroxide, the cell loses its E. M. F. entirely.

(*e*.) The action seems to take place most rapidly where the current density is greatest; the plate gets hard there from sulphate soonest on discharge, and oxidizes quickest on charge.

If the energy given out by the cell be produced by the conversion of $Pb\,O_2$ in the positive plugs, and of Pb in the negative, into lead sulphate, a constant value of the P. D. at the terminals of the cell when a constant current is passing through it ought to correspond with a constant rate of variation of the percentage of $Pb\,O_2$ in the positive plugs; so that for a constant current

$$\text{the terminal P. D. should} \propto \frac{d\,(Pb\,O_2)}{dt},$$

t representing time. This connection is seen to exist fairly well in the case of the discharge where the slope of the $Pb\,C_2$ curve is roughly constant as long as the P. D. is constant, and acquires a less inclination to the axis of time when the P. D. is rapidly falling. In the case of the charge, the connection between the value of the P. D. and the slope of the $Pb\,O_2$ curve is not so easily seen; but this arises from the fact that towards the end of the charging there is a rapid rise in the resistance of a cell, and therefore in the P. D. required to send a constant current through it; further, the back E. M. F. steadily increases during charging on account of the polarization, which grows larger and larger from the continuous evolution of gas at the surface of the plates.

For the purpose of examining into what took place in an accumulator which was left charged, a small E. P. S. cell was charged until the P. D. was 2.4 volts, and then the positive plates were withdrawn and put into another vessel containing dilute acid of specific gravity 1.2, the negatives being left in the vessel in which they were charged. Both sets of plates were covered up with gutta-percha hoods the edges of which dipped under the liquid, and to the top of each hood was fitted, gas-tight, a vertical graduated glass tube closed at the top. The hoods and the glass tubes were first filled with liquid, and the amount of gas that came off from the two sets of plates was measured from day to day by watching the descent of the liquid in the tubes.

No gas was seen to come off from the positive plates, but in the case of the negatives gas came off very slowly at first, then more rapidly, and finally more slowly again.

The lead of the positive plate was turned into lead sulphate by local action, the 87 c.c. of hydrogen liberated corresponding with about 0.81 gramme of lead turned into sulphate. It is clear, then, that the lead of the negative plate is steadily being turned into some oxide or salt, and probably the loss of energy which we observed in the charged cell left insulated for many days was due to this local action at the negative plate.

CONSTRUCTION AND FORMATION OF E. P. S. PLATES.

The question arises why the E. P. S. accumulators are so constructed that the plugs in the positive plates contain some 48 per cent. more peroxide of lead than is required to be converted into sulphate in the normal discharge. Two explanations suggest themselves. One is that, since the granules of lead peroxide begin, as we find, to be coated with a protecting coating of sulphate early in the discharge, it is impossible, with the present form of plate, for the interior of each granule of lead peroxide to be converted into sulphate, and therefore it is necessary to employ nearly twice as much lead peroxide as is actually needed for the chemical action. Another reason is the fear of the positive plate crumbling to pieces if it be completely formed; and this reason Mr. Capito, who was formerly in the employ of the Electrical Power Storage Co., thinks, on the whole, is the more important.

In the construction of the original Faure accumulators, as well as of the early E. P. S. cells, both the positive and the negative plates were pasted with red lead ($Pb_3\,O_4$), and formed together for a period of some 50 hours. Later on litharge ($Pb\,O$) was used to coat the negative plate, red lead being used only for the positive one, and the plates were formed separately, the negative being much more formed at the works than the positive. Some time ago I was informed by a very competent authority that the following is the modern process of *forming* employed by the Electrical Power Storage Company:—

Positive Plates.—8⅜" by 7⅞" by ¼". Two amperes per plate, or 0.028 ampere per square inch, sent for 18 hours.

Negative Plates.—9" by 9⅝" by 3/16". One and a half to two amperes per plate, *i. e.*, 0.017 to 0.023 ampere per square inch, for 120 hours.

The actual time of forming either set of plates depends greatly on the length of stoppages during the formation. This is especially the case with the negative plates, therefore they endeavor to form the negatives for the 120 hours without any stoppage of the current. On the receipt of a cell from the Electrical Construction Corporation, the purchaser is requested to form it for 40 hours more with the ordinary charging current used in working, which is at the rate of 0.026 ampere per square inch.

The reason, we understand, for the manufacturers only forming the positive plates for 18 hours, and leaving the purchaser to form them for the remaining 40 hours, is that if positive plates be *well formed* and then dried for carriage, the plugs become loose, which is not the case if the positive plates be only slightly formed before drying.

We were interested in learning from Mr. Capito whether, while superintending the manufacture of many thousands of accumulator plates, he had ever tried pasting the positive with lead peroxide ($Pb\,O_2$) in order to avoid the necessity of having to form this salt electrically out of the red lead with which the positive plates are usually pasted. This idea of applying a paste of lead peroxide directly to the positive plate, he told us, he had tried, but that the method turned out a failure, from the impossibility of getting the lead peroxide paste to stick on to the grid even when some red lead was mixed with the lead peroxide. He also mentioned a very interesting fact—that whereas a paste of red lead mixed with dilute sulphuric acid of density 1.1 gives an adherent deposit on formation, on the contrary, a powdery deposit is produced if the density of the liquid used in making the red lead paste be 1.3. We understand the process that has shown itself the best is to use dilute sulphuric acid of density 1.1 for mixing the red lead paste, and dilute acid of 1.2 for mixing the litharge paste for the negative plates.

THE EVOLUTION OF ELECTRIC AND MAGNETIC PHYSICS.[1]

BY A. E. KENNELLY.

THIS address was one of a series treating of the evidences of evolution in the advance of the arts and sciences. It was necessarily and largely of a historical nature, touching in rapid review the various developments in electricity and magnetism as distinct fields and also as subjects that more and more exhibited a tendency to resolve themselves into one effect, under differing manifestations, just as static and dynamic electricity have gradually become identified with each other. The leading conclusions of the address were :

First : In electromagnetic science the great achievement since Faraday's time has been the determination of the fact that all electricity flows or tends to flow in closed curvos or circuits so that we have the electrostatic circuit, the galvanic circuit and the magnetic circuit, each resembling as it were an endless chain or a bundle of endless chains ; and the laws which control these three different types of circuit show wonderful analogies.

Second : The due appreciation of the influence of the ether and its importance in all electromagnetic phenomena. While originally the electrical activity seemed to be confined to the battery or conducting wires of a galvanic circuit, it is now believed that the other surrounding these conductors plays fully as active a part in the process of conduction, so that the mind sees free space no longer void but filled with an active and responsive substance, the ether. Once more in the evolution of thought, the tide of belief has turned, and we hold with Torricelli, under somewhat altered premises, that "Nature abhors a vacuum." The properties of the ether almost threaten to surpass in interest and importance the properties of the matter it environs and pervades.

Third : The evidence in favor of the proposition that light is a vibratory disturbance in the ether of an electromagnetic nature, in such as almost to amount to demonstration. When this shall be generally accepted, the whole domain of optics and radiant energy will be enrolled as one department and property of electromagnetic physics.

Difficult as it is to clearly apprehend the course of evolution in the near past, where events press upon us in narrow bounding throng, and the workers at the great loom of history yet stand by the mesh their hands have helped to weave, how still more difficult it is to guess the future. The prospect that opens is however a brilliant one. We may well believe that in science the same evolutionary process which has united electricity and magnetism, and welded both with radiation, will continue to magnify, simplify, and unify. Contrary to the course of evolution in the organic world, "from the homogeneous to the heterogeneous, the simple to the complex," the development of science is from the heterogeneous to the homogeneous, from the complex to the simple, and just as the evolutionary course of religious belief has been from polytheism to monotheism, so with every fresh acquisition, science becomes greater, and grander, and more succinct.

In arts electricity is destined even apart from future discoveries to take into its own hands the distribution of power. The telegraph has conquered time, and the electric motor is born to triumph over space ; but whether we watch the vibration of the telegraphic recorder that spells its message across the sea, or watch the electric car, urged by invisible hands, pursue its stealthy way, the rhythmic words of Ruskin rise into recollection's sight, "Not in a week or a month or a year, but by the lives of many souls. a beautiful thing must be done."

Letters to the Editor.

A RIVAL TO THE KEELY MOTOR.

Can you get full information from London, or otherwise, in relation to the alleged discovery referred to in cutting herewith? If so would it not be of great interest to your readers? Should you now have, or be able to get, any information on this point I trust you will print it. G. E. TEWKSBURY.

TOPEKA, KAN.

A continental paper, devoted to finance, has the following in a recent issue : "Dr. Mandeuft, of Geneva, has found out a way of producing electricity for nothing. With a half-horse machine he can feed 500 lamps. The apparatus is made up of a hollow sphere of zinc of 50 cm. diameter, and a massive sphere of copper 40 cm. diameter. The copper revolves inside the zinc sphere, and the two revolve at the same time, but in opposite directions, at the rate of 500 revolutions a minute. Steam at a pressure of six atmospheres is delivered into the gap between the spheres and a current is produced, the pressure of which may be increased by increasing the revolutions and the steam pressure. Trials made in London with M. Mandeuft's new machine are quite bewildering the scientific world."

[While Dr. Mandeuft, whoever he may be, should find no difficulty in running 5 lights from a ½ h. p. machine, he certainly could never run 500 ; and the statement as to the 500 lights discredits the whole story, even if it were not otherwise open to suspicion. Dr. Mandeuft may possibly get either a chemical-electric, a thermo-electric or a mechanical-electric effect from such an apparatus, but we should not expect to obtain very much under the conditions enumerated.—EDS. E. E.]

European Correspondence.

LONDON.

The Progress of Electric Lighting in London.

I MENTIONED in my last letter that Mr. Bailey was down for reading a paper before the Society of Arts on the progress of electric lighting in London. It was read before a goodly muster of Fellows under the presidency of Sir Frederick Bramwell. Although showing signs here and there of hurried compilation, it is undoubtedly the most authentic record of the complete work done in London, and, as Prof. Kennedy said at the time, it will be much quoted at a subsequent period. The lecturer in his opening remarks said that the electric lighting Act of 1882, though stifling inordinate speculation on the part of the public, had the effect of checking any advancement of electric lighting. After giving a general description of the stations in work, interesting figures were advanced. From these I gathered that the total equivalent number of 32 watt lamps, now in use in London, is approximately as follows : Public companies supply 179,060 and private plants work 85,000, which gives a total of 264,060, and the present rate of increase shows an addition of at least 4,000 lamps per week. Arc lamps are not very successful in figures, for the total does not go far beyond a thousand.

The lecturer thought it was a regrettable matter that there had not been any progress in the efficiency of the incandescent lamp. The future progress of electric lighting depended in no small measure on the lamp makers, and as the manufacture of the incandescent lamp would soon be open to all, the absolute necessity of a standardizing laboratory must compel its adoption where not only instruments but lamps could be tested.

In the course of the discussion which followed the reading of the paper, Mr. Bailey said, so far as he could ascertain there were now 81¼ miles of conduits of all kinds into which were laid about 111 miles of cables which were actually carrying current at the present moment. This had been completed in about eighteen months.

Referring to overhead lines, there were in London about 25 miles, and he had not heard of a single accident due to them. The prejudice which existed against them was due to the wretched work done in New York, where they neither properly suspended nor insulated their wires.

Sir F. Bramwell considered that the large number of private installations compared with public ones was due entirely to the baneful clauses of the original act.

Mr. R. E. Crompton thought electrical engineers ought to feel proud that though they had been so heavily handicapped in the race, they had begun at last to bring London to the front, and it would not be long before they would be as far ahead of any other town in the world in electric lighting as they were in most other respects.

Prof. Kennedy, F. R. S., said, in his opinion there was no other city in the world which had 250,000 lights. He believed it was about double the amount in use in New York, and before long people will be coming here for information instead of scoffing. With regard to safety in working a station, there should always be power in reserve equal to one of the largest units; if 200 horse-power engines were the largest used, for instance, there should be 200 horse-power in reserve.

Prof. Forbes said he had taken pains to learn what was being done in other countries by personal inspection, and had frequently on his return from such inquiries done his best to impress on those concerned at home, the superiority of the work done abroad. The last time he had occasion to do so was about three years ago, when hardly any of the work now described had been commenced, but he now concluded that there was not an example in the whole world of such enormous progress in so short a time.

CHICAGO.

A New Submarine Boat.—Fire in the Calumet Station.

THE Detroit Boat Company is constructing a submarine craft which is expected to achieve remarkable results. The vessel is 40 feet in length, 9 feet beam and 14 feet deep. The mechanism is similar to that used in submarine torpedo boats.

Electric storage batteries will be employed for furnishing the necessary motive power and giving light. The improvement over the torpedo boat is claimed to be the buoyancy of the craft, which will rise to the surface as soon as the electric motor is stopped, whereas in the torpedo boat the machinery must be working to bring it to the surface of the water. In addition to a screw at the stern, there will be two wheels on either side of the new vessel. By simply turning an electric switch the boat will immediately rise or plunge deeper in the water. It is being constructed as a pleasure boat, but if it proves as successful as expected, the government will be requested to consider its adoption as a torpedo boat.

---

[1] Abstract of address before the Brooklyn Ethical Association, Dec. 28, 1890.

A disastrous fire occurred last week in the power house of the Calumet Electric Light Company near South Chicago avenue and 95th street. On the alarm being given, eight engines arrived upon the scene, and the firemen found a lively fire rendered especially dangerous from the fact that the station stands in close proximity to the gas house and tanks of the Chicago Gas Company. For some time it was thought the gas works would catch in spite of the efforts of the firemen, but fortunately this did not occur. The origin of the fire is unknown, and the loss has not yet been estimated. The lights went out shortly after the fire commenced, and it is thought the valuable machinery is damaged beyond repair.

CHICAGO, Jan. 1, 1891.

Society and Club Notes.

THE NEW YORK MAGNETIC CLUB.

Mr. George F. Fagan, secretary, gives notice that the annual (business) meeting of the Magnetic Club will be held in Room 29; at 195 Broadway, on Thursday, the 8th of January, 1891. at 4.30 o'clock. p. m., for the election of officers and four members of the Governing Committee, and such other business as may properly come before the meeting. The date of holding the next social meeting is under advisement of the Governing Committee, and will be announced soon.

NEW YORK ELECTRIC CLUB.

The weather was stormy and gloomy on New Year's day, but within the hospitable doors of the Electric Club reigned an atmosphere full of sunshine and jollity. The muster of those who wished to welcome in the new year with good fellowship was large, and the club walls have never before listened to so much hearty laughter or to so many really new stories. The noble punch bowl presented by Col. H. R. Garden was duly brought out and honored, not in the breach but in the observance, and the task of the punch-brewer proved so onerous that he still doubts whether January 1 can be called a holiday.

Appointments, Etc.

MR. C. K. MINARY, of Louisville, Ky., succeeds Mr. N. McD. Crawford as manager of the electric railway at Rochester, N. Y.

MR. W. WEBER, of the Louisville, Ky., Adams Express office has been offered the secretaryship of the Consolidated Electric Light and Gas Heating Co. to succeed Mr. F. Poindexter.

MR. W. H. MCCLURE has been elected city electrician of Worcester, Mass., in the place of Mr. C. M. Mills.

MR. JOSEPH E. LOCKWOOD has been presented with a chain and charm on the occasion of his retirement from the managership of the Brush station in Detroit. Mr. H. L. Wilton succeeds him.

MR. JAMES NORTHLEY, formerly of Charlotte, N. C., is now in charge of the Asheville telephone exchange. Mr. J. S. Bixby is with the exchange at Charlotte.

MR. W. M. BESSON, the superintendent of the Bell Telephone Co. at Cincinnati, is dead. Resolutions of regret and sympathy have been adopted by the employés.

MR. D. HARRIS has been succeeded by Mr. Yarnall as superintendent of the Haverford, Pa., Electric Light Co.

GEN. E. H. BROADHEAD, of the Wisconsin Telephone Co., Milwaukee, died Sunday, Dec. 14.

A LARGE ELECTRIC MINING CONTRACT IN PENNSYLVANIA.

The contract for what will be the largest electric mine haulage plant has recently been given to the Edison General Electric Co. by the Loyalhanna Coal and Coke Co., of Philadelphia. This plant will consist of one locomotive, capable of delivering hourly 120 mine cars to the bottom of the shaft, each car containing 2½ tons of coal. This would make the output 300 tons of coal per hour and a total work of 375 ton miles per hour; the gross weight of the trains to be hauled will be 120 tons. About 3,000 lineal feet of gangway will be equipped with conductors at the start, but as the gangways are extended this will be increased to 10,000 feet, and it is then expected to put in a second locomotive of equal capacity with the one mentioned above.

Reports of Companies.

SKOWHEGAN, ME., ELECTRIC LIGHT COMPANY.

At the annual meeting of the Skowhegan Electric Light Company, Ed. P. Page, A. H. Weston, C. A. Marston, William Duran, of Skowhegan, and S. B. Paine, of Boston, were elected directors; A. R. Bixby, treasurer; M. B. Heselton, clerk; George Cushing, auditor. The treasurer's report showed the receipts for the year to be $16,392.39; running expenses, $8,277.30, making the earnings on the stock nearly 16 per cent., 5 per cent. of which has been paid to stockholders. There is about $1600 in the treasury, the balance has been paid out for improvements made upon the plant. The company are now running about the full capacity of their plant. They have lately closed a contract with the county-commissioners to light the county jail at Norridgewock for one year.

ELECTRICAL INTERESTS IN MILWAUKEE.

Owing to the consolidation of the Villard properties in Milwaukee, Superintendent Linn, of the Cream City Street Railway, will retire, and Superintendent Hommel, of the Milwaukee City Company will assume managerial control of the consolidated corporations. The officers of the new corporation are as follows: Henry Villard, president; Henry C. Payne, vice-president; directors, Charles L. Colby, Colgate Hoyt and W. J. Curtis, of New York; Frank G. Bigelow, of Milwaukee, and David S. Wegg, of Chicago.

THE NARRAGANSETT ELECTRIC LIGHT CO., OF PROVIDENCE.

A proposition will be brought before the stockholders of the Narragansett Electric Lighting Company, at a meeting to be held Jan. 14, that new stock to the amount of $200,000 be issued at par and offered to the stockholders and certificate holders in the proportion of one share of new stock for every three shares or certificates of outstanding stock.

This will enable the company to retire its floating debt as it matures, and leave a surplus for improvements. The total amount of outstanding stock is now about $400,000.

THOMSON EUROPEAN ELECTRIC WELDING CO.

Francis Peabody, Jr., treasurer of the company, in a circular says:

"Seventy thousand pounds have been received from the City of London Contract Corporation by the Thomson European Electric Welding Company. Of this amount £10,000 were paid as a forfeit because the contract corporation failed to buy the continental patents within the time for which that corporation had an option, and £60,000 have been paid on account of the purchase of the British patents. There is still to be paid by the contract corporation, as purchase money for these British patents, £40,000 in cash, 400 founders' shares and one-third of the ordinary shares of the English Electric Welding Company (limited), before our company assigns the patents to that company. Owing to the bad state of the money market in London, it has been absolutely impossible for the contract corporation to bring out the British company with a fair prospect that the shares would be subscribed for, and it has been agreed that the time for paying the balance of the purchase money and bringing out the company shall be extended until Feb. 28, 1891. Meanwhile, the money already received, less the expenses, has been deposited in a trust company in Boston upon interest, while the balance of cash unpaid, £40,000, is also drawing interest from the contract corporation."

The patents for other European countries are still in hand to be disposed of, and sooner or later will bring valuable returns.

THE CONSOLIDATION AT PLAINFIELD, N. J.

The Plainfield Gas and Electric Light Company organized Dec. 30, by the election of the following officers: President, E. R. Pope; secretary and treasurer, H. G. Runkle; directors, Wm. Runkle, H. G. Runkle, and E. R. Pope. This new company has leased the entire plant of the Plainfield Gaslight Company and has puchased outright the Plainfield Electric Light Company's works, thus securing a complete monopoly of public and private lighting. The company promises a better service and a material decrease in the cost of illumination to consumers.

BELL TELEPHONE OUTPUT.

The Bell Telephone output for month ended Dec. 20 was 5542, a gain of 532. Returned, 3171, a gain of 1031. Net, 2371, a decrease of 499. Jan. 21 and Dec. 31 output, 64,647; increase, 748. Returned, 27,878; increase, 2911. Net, 36,769; increase, 4569.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED Dec. 30, 1890.

Accumulators :—

Secondary Battery. H. H. Wardwell, 443,556. Filed Sept. 2, 1890.

The plate or electrode has cavities formed in it, each cavity being open at one side of the plate and having a bottom at the other side for the retention of active material ; a reticulated or lattice-work cover, having enterstices opposite each of the cavities, is secured upon each side of the plate or electrode.

The patent further includes details of the construction of cells or battery cases and of the means for connecting the electrodes in series in each cell and for connecting the cells together in batteries.

Alarms and Signals ;—

Electrical Fire-Alarm and Extinguishing System, C. E. Ongley, 443,724. Filed Apr. 12. 1890.

The invention relates particularly to protective systems in which thermostats are distributed through buildings to be protected and the circuits are led to the office or other suitable point at which is located apparatus arranged to be released by the operation of the thermostats and to record or signal automatically the number or location of the particular thermostat from which the alarm has arrived, and which thermostat will have released sprinkling apparatus for the extinguishment of fire. The special object of the present invention is to provide a signal or alarm to indicate an accidental breaking or disarrangement of the automatic sprinkler and to secure the prompt closing of a water valve or valves upon a false alarm from the thermostat. Provision is also made to secure non-interference between different classes of signals.

Non-Interfering Signaling System. C. E. Ongley, 443,725. Filed May 9, 1890.

Improvements in apparatus for use in fire-alarm, fire-telegraph, hotel annunciator and other similar systems in which it is required to send distinct signals from several points to a common receiving station. The invention is chiefly directed to securing the non-interference of signals from different boxes.

Electrical Signal System, C. E. Ongley, 442,726. Filed May 13, 1890.

The object of the invention is to provide means by which a signal receiving device having a number of operating magnets may be operated over a single line wire, either of the electro-magnets of the receiver being actuated at will from the transmitting station. The two or more operating magnets of the receiving apparatus are in separate local circuits or branches; an automatic distributor or switch, driven by a motor is employed to control the selection of the proper local circuit by the signal from a transmitting station.

Watchman's Electric Time Recorder, C. E. Ongley, 443,787. Filed Jan. 20, 1890.

Employs time printing type-wheels controlled by a clock movement, printing mechanism and an electro-magnet controlling the printing mechanism, and a number-printing type wheel controlled by a second and independent electro-magnet.

Watchman's Electric Time Recorder, C. E. Ongley, 443.788. Filed March 17, 1890.

Amplification of the system disclosed in No. 443,787, above.

Electric Protective and Signaling System, C. E. Ongley, 443.790. Filed Nov. 26, 1889.

A general system of electrical circuits and apparatus for large buildings, such as factories and hotels, to provide a system of indications or signals at a central point from various parts of a building and for various purposes, such as watchman's time-signals, with permanent record, indications of the time of starting and stopping of engines, fire alarm signals, with provision for the automatic control and operation of fire-extinguishing apparatus.

Electrical Annunciator, J. W. Luthe and A. E. Jeavons, 443.834. Filed Jan. 23, 1890.

The electro magnets of an annunciator are constructed as induction coils, with primary and secondary windings. The primary windings are exterior and are connected to battery and call-bell on the one side, and to the various push-buttons on the other side in multiple arc, in the usual manner. The secondary windings, immediately upon the cores of the magnets, and which directly actuate the pointers, are connected in series throughout.

Conductors, Conduits and Insulators :—

High Resistance Compound. W. G. Bremer, 443,497. Filed June 6, 1890.

Consists of graphite and shellac.

Art and Means for Covering and Insulating Wire, T. W. Norman, 443.536. Filed April 29, 1890.

Consists in treating the insulated wire so as to render it proof against burning or damage by contact for a few seconds with molten metal ; the insulated wire is passed centrally through a chilling mold and molten metal is poured around it as it is fed through the mold.

Machine for Covering Electrical Conductors with Lead, F. H. Stillman, 443.551. Filed June 6, 1890.

Claim 1 follows :

The combination, with a die-block having a lead-chamber formed therein and openings for the core-bar and die, of a sleeve supported within the lead-chamber in proper relation to the die, and a hollow core-bar seated in said sleeve.

High-Resistance Compound, W. G. Bremer, 443,565. Filed Oct. 31, 1890.

Claims 1 and 2 follow :

1. A homogeneous high-resisting composition or compound consisting of rubber, shellac and graphite, substantially as and for the purposes described.

2. A homogeneous high-resisting composition or compound consisting of rubber, sulphate of baryta, graphite and shellac, substantially as and for the purposes described.

Apparatus for Laying Electric Conductors, T. J. Cope, 443,823. Filed May 22, 1890.

Employs a projectile, propelled by compressed air, to convey a wire or cord through a conduit. The patent covers special devices for operating such a system.

Apparatus for Laying Conductors in Conduits, T. J. Cope, 443,821. Filed Sept. 4, 1890.

Consists of an apparatus for conveying a wire or cable through a conduit having a head, a tail piece, a carrier and guiding rods. The entire apparatus moves through the conduit and is advanced by successive motions controlled by ropes extending from its rear to the man-hole or other point of insertion. The mechanical construction of the device is such that the pulling of one rope effects the clamping of the tail piece against the sides of the conduit while advancing the carrier with the wire or conductor ; and the pulling of the other rope clamps the carrier in like manner and advances the tail piece.

Dynamos and Motors :—

Electric Motor, C. J. Van Depoele, 443,980. Filed March 8, 1889.

Motor especially adapted for alternating, intermittent or pulsating currents ; intended, among other things, to obviate the necessity of synchronism between the armature speed and that of the generator supplying the current for efficient action on the part of the motor, and thus to enable motors to run with efficiency at low speed or in starting a load—as, for example, in electric railway work. The armature, preferably of the ring form, continuously wound, has conductors extending across at right angles with each other and electrically uniting diametrically opposite portions of the armature conductor to form two or more closed circuits therein. In large armatures more than two such cross connections may be used to advantage. In addition to the usual field magnets the armature is surrounded by a separate stationary electro-magnetic system for producing magnetizing currents therein by induction and thus establishing poles in the armature core. The non-rotating induction coil surrounding the armature may be made adjustable with respect to the poles of the field magnets.

Galvanic and Thermo-Electric Batteries :

Galvanic-Battery, G. A. Smith. 443,976. Filed July 14, 1890.

Design and construction of a battery cell containing one or more rods of zinc and one or more rods of carbon, with mechanism for plunging and lifting the elements and for holding them at any desired height.

Lamps and Appurtenances :—

Socket for Electric Lamps, C. A. Lieb. 443.530. Filed Sept. 24, 1890.

The socket it is made of one piece of non-conducting material, which should be water-proof, and has cast in it or otherwise embedded, the conductors, holding them in place without the aid of screws or other fastenings. It is intended to avoid all short circuiting by water, snow or ice ; the conductors are located within a hermetically sealed chamber.

Incandescent-Lamp Socket, S Bergmann, 443,562. Filed Jan. 10, 1890.

Construction and arrangement of parts designed to secure simplicity and to obviate the twisting or abrasion of the circuit-wires by the outer shell.

Arc Lamp, A. W. Whitcomb, 443,557. Filed March 27, 1890.

Relates to the class of arc lamps in which the upper carbon is lifted to strike the arc by the action of an electro-magnet in the main circuit and is fed by the action of gravity controlled by gearing. There are two releasing devices for the feeding mechanism, one actuated by the main current and the other by a shunt current, each independent of the other.

Shade-Holder for Incandescent Lamps, S. Bergmann, 443,563. Filed Jan. 25. 1890.

The shade-holder has segmental sections elongated in the direction of the length of the socket and concentric throughout their extent, forming a tubular collar.

Switch, E. H. Johnson, 443,606. Filed Jan. 21, 1885.

Designed to control the separate circuits of several electric lamps or groups of lamps by a single apparatus, and adapted to throw the lamps or groups of lamps successively into or out of circuit, so that one or all or any intermediate number of the lamps or groups may be lighted or extinguished.

Lamps and Appurtenances.

Electric Street-Light. G. M. Kim. 443,097. Filed May 19, 1890.

A design and construction of a mast arm for electric street lights.

Electrical Signaling Apparatus, A. B. Wyckoff, 443,157. Filed May 5, 1890.

The invention consists in devices for flashing an electric light for signaling or other purposes. For a lamp or group of lamps there is provided a rotating shaft having projecting arms in different planes, and segments, one for each arm, one segment serving to direct the current to the lamp or lamps and the other segment shunting the current back to the dynamo. The object is to flash the lamp instantly up to its full power and to extinguish it instantly.

Circuit Breaker and Closer. J. S. Potter & D. J. Cartwright, 443,401. Filed Aug. 16, 1890.

Design and construction of circuit-breaker and closer particularly adapted for the key-sockets of incandescent electric lamps.

Gas and Electric Lamp Fixture, C. Felton, 443,487. Filed Dec. 23, 1889.

A device for securing the canopy of a gas or electric light fixture in position through frictional contact.

Electric-Arc Lamp, E. Heymann and F. W. Heymann. 443,632. Filed Nov. 5, 1888.

The feed rod is of magnetic metal ; an electro magnet having shunt and main windings has its core mounted axially and extending across the feed rod and carrying a pole-piece the magnetism of which controls the feed rod ; one or more pole-pieces act with a second magnet to move the controlling magnet on its axis.

Electric Arc Lamp, E. Heymann and F. W. Heymann, 443,633. Filed Nov. 5, 1888.

Regulator consists of two electro-magnets controlled by shunt and main currents ; their cores are mounted axially cross-wise of the feed rod, the pole pieces of the cores forming rocker-arms and the feed-rod being gripped directly between two opposed pole-pieces.

Electric-Lamp Socket, J. T. Dempster, 443,743. Filed May 24, 1890.

Designed for simplicity and permanence of adjustment. The circuit is complete independently of the outer sleeve, there being no electrical connection between the exposed portions of the socket and the screw threaded sleeve into which the lamp base is affixed.

Attachment for Electric-Arc Lamps, A. Manning, 443,944. Filed Sept. 24, 1890.

A guide for securing the alignment of the two carbons.

Electric Switch, J. J. Wood, 443,693. Filed May 28, 1890.

For closing or opening circuit, or for throwing in or out a loop. Especially adapted for use on lighting circuits. A "quick-action" or "snap" switch. Consists in a new mechanical movement for switches of the class in which the actuating device acts first to store up the power required to throw the switch—as, for example, a spring—and then by its further movement to bring the stored power into action to throw the switch instantaneously.

Measurement :—

Apparatus for Measuring and Registering Electric Currents, C. A. Faure, 443,636. Filed Nov 1, 1888.

A motor-meter, based upon the principles that a conductor conveying a current tends to rotate in a magnetic field ; employs a rotary non-commuting electric motor to actuate the registering mechanism.

Electric Meter, C. P. Elieson, 443.612. Filed March 18, 1890.

An electrolytic meter ; provides for ascertaining the quantity of current which has passed in a liquid, either by measuring the volume of gas generated or by registering the pulsations caused by the accumulation of gas as it is generated. In connection with the latter method there is provided a mercurial trap which permits the flow or escape of gases at intervals only when a definite pressure has been obtained.

Metal Working:—

Methods of Electric Soldering and Cementing Cans, M. W. Dewey, 443,748. Filed Oct. 4, 1890.

Adaption of electric heating to the processes of soldering and sealing cans; designed especially for application to capping machines now in use without material alteration in their construction.

Apparatus for Electric Soldering and Cementing Cans, M. W. Dewey, 443,749. Filed Oct. 4, 1890.

Amplification of the devices of patent 443,748 above.

Medical and Surgical:—

Electrical and Vapor Face-Bath. N. Lyke, 443,580. Filed Apr. 25, 1890.

The pan of a vapor face-bath is provided with detachable electrodes.

Miscellaneous:—

Apparatus for Preventing Steam Boiler Incrustation, J. Langstaffe, 443,598. Filed Feb. 10, 1890.

A disc of finely divided material secured between a positive and a negative electrode is suspended in the water space of a boiler. The theory of the invention is that an electric current is generated by the impure water between the positive and negative electrodes, and that the impurities are deposited upon the disc of finely divided material.

Magneto-Electric Stop Mechanism, W. H. Kilbourne, 443,646. Filed June 4, 1890.

Magneto-electric apparatus designed for use in factories, and like places, by which the supply of power to machinery may be stopped instantaneously from any point in a building. A belt-tightner or "idler-pulley" is shifted through mechanism controlled by an electro-magnet.

Electric Stop-Motion for Warping-Machines, P. Goldschmidt, 443,674. Filed Jan. 11, 1890.

A warping or similar machine is provided with a dial for indicating the number of yards of thread being wound and electro-magnetic devices for actuating a stop-motion. The creel is provided with faller-wires adapted to close the electric circuit upon the breaking of a thread.

Electric Damper-Regulator, J. O'Meara, 443,716. Filed May 2, 1890.

Employs the expansion of German silver wires, or equivalent electric conductors, under the passage of a current for operating the controlling devices in one direction and the contraction of the conductors when the current is cut off for operating the devices in the opposite direction.

Safety Device for Dynamo Stations, C. E. Ongley, 443,727. Filed June 30, 1890.

Designed to shut off current when a fusible cut-out or other safety device in a dynamo-circuit has burned out and an arc has been formed. Provides for the stoppage of any one dynamo in a station, and in extreme cases for the stoppage of the engine; also controls the operation of sprinklers or fire extinguishers.

Electro-Magnetic Clutch, C. E. Kells, Jr., 443,772. Filed March 31, 1890.

Applies to a power driven shaft a wheel or pulley loosely mounted thereon, an electro-magnet and its armature, connection between the armature and the wheel, a retractile spring for the armature, a friction block with which the wheel engages when the armature is withdrawn from the magnet, and a friction collar with which the wheel engages when the magnet attracts the armature.

Electric Valve-Controller, C. E. Ongley, 443,789. Filed April 4, 1890.

Electro-magnetic device for the control of a comparatively large valve which is moved by fluid pressure through the agency of a second valve; the second valve being actuated by an electro-magnet.

Railways and Appliances:—

Pole-Top for Trolley-Wire Supports, W. Le R. Emmet, 443,508. Filed Sept. 18, 1890.

First claim follows:

The combination of a metal pole, a plug or block of insulating material attached to the upper end of said pole, a hollow metal top resting upon said plug or block and inclosing a portion of the top of said pole, and a sleeve of insulating material inserted between said pole and said top.

There is also described an out-rigger made of two metal rods bolted together, the rods bowed out at one end to clamp the whole.

Apparatus for Automatically Grounding or Cutting Out of Circuit Exposed Electrical Conductors, F. W. Jones, 443,527. Filed Aug. 15, 1890.

Especially applicable to the conductors of electric railways. Along with a continuous main line conductor there is provided a guard wire having earth connections at stated intervals and circuit-controlling devices normally open and adapted to become operative upon the breakage or falling of the main conductor.

Traction and Brake Device for Electric Railways, R. M. Hunter, 443,661. Filed Sept. 23, 1886.

Consists essentially of a helix upon a hollow iron core and adapted to embrace or surround the lower part of the wheel of a railway car. Intended to magnetize the wheels and thus increase traction; intended also to act as a brake when brought into contact with the wheels.

Electric Locomotive, R. Eickemeyer, 443,671. Filed Jan. 28, 1869.

Application of the inventor's "iron-clad" type of motor to railway cars, and including special methods of attaching the motor to the car and of transmitting the power from the motor to the car axle.

The shell or casing of the motor, which constitutes a part of its magnetic system, serves also as a magnetic shield between the interior of the car or locomotive and the magnetic field of the motor, protecting watches or other property of passengers from exposure to magnetization. The motor is suspended directly from the under side of the sill-framing of the car. The armature shaft of the motor is operatively connected with the axle of the car by means of pitmen connecting the motor shaft with a counter-shaft occupying the same vertical plane as the axle and carried thereon, but coupled by links or frame pieces hinged to the motor on bearings concentric with the motor shaft. The counter shaft is so geared to the axle that the meshing point of the gears is in the vertical plane of the counter shaft and axis.

Traction and Brake Device for Electric Railways, R. M. Hunter, 443,677. Filed Sept. 23, 1886.

Similar to No. 443,661, above.

Electrical Attachment for Railway-Switches, A. W. Berne, 443,814. Filed July 5, 1890.

Electrical apparatus providing for ringing a bell in the cab of a locomotive when a train is approaching a switch which has been misplaced.

Telephones and Apparatus:—

Telephone, S. Bergmann, 443,493. Filed Dec. 31, 1884.

Claim 2 follows:

The method of reproducing articulate speech from telephone-current vibrations, consisting in passing the electric current axially through a magnet, thereby varying its force in conformity with the current changes and moving a sound-producing body by the varying force of such magnet.

Telephone, S. Bergmann, 443,494. Filed Oct. 26, 1885.

In a telephone transmitter, in place of the ordinary button and stud contacts the inventor employs two metal rods making end contact, one of them attached to the centre of the diaphragm and the other held rigidly in place in the frame of the instrument. The contact points of the rod may be formed of platinum, and the rods may be magnetized steel. Such magnetized steel rods are specified in claim 2.

Telephone, E. H. Johnson, 443,526. Filed April 24, 1884.

A telephone transmitter in which variations of current strength are obtained through the impingement of the diaphragm upon a greater or less number of contact points or electrodes connected to definite units of resistance located in shunt circuits around the electrodes.

Legal Notes.

DECISIONS AS TO THE DUTY ON ELECTRICITY AND NATURAL GAS.

The Treasury Department, at Washington, through Assistant Secretary Spaulding, has recently made two decisions which have attracted a great deal of attention from those interested. Recently a clerk of customs of one of the ports of the Texas border made inquiries of the department as to the tax which should be assessed against a certain electric company which was wiring its electricity across the Rio Grande into American territory. Secretary Spaulding decided that inasmuch as electricity is intangible and as he puts it, cannot be measured, electricity might come in free.

About the same time Clerk Morgan, of Buffalo, inquired how he should treat the importation of a certain company in Buffalo who had made arrangements to bring natural gas across the Niagara river from Canada into the United States through the medium of an eight-inch pipe.

In this case the Treasury Department prepared a decision which the assistant secretary signed, in which he holds that natural gas is an unmanufactured product not otherwise provided for, and is therefore dutiable at the rate of 10 per cent. ad valorem. The manufactured product electricity can be brought into the United States free under this decision, but the unmanufactured natural gas from which electricity could be produced is taxable at the rate of 10 per cent. The Buffalo concern, if it desires to evade this 10 per cent. tax, can turn its gas fuel into an electric current on the Canadian side of the Niagara river, and carry it across the river through wires instead of pipes. This they can do under Assistant Secretary Spaulding's decision, without regard to customs laws.

SUIT FOR DAMAGES TO TELEPHONE CIRCUITS BY THE ERIE, PA., ELECTRIC ROAD.

The New York and Pennsylvania Telephone Company has begun an action against the Erie Motor Company in the Court of Common Pleas for trespassing, laying damages at $50,000. The telephone people allege that the Motor Company's wires have damaged the value of their franchise, and that by induction the telephone service in Erie has been greatly damaged. The right to claim damages is attached to priority privileges. The Telephone Company claims to have expended large sums of money to correct the interference, but without avail.

Metal and Supply Market.

CONFERENCE OF THE WIRE MILLS.

A special dispatch from Pittsburgh, of Dec. 31 says: "A conference of wire manufacturers is in session here, the subject being to devise means of curtailing the output of the mills and to advance prices. It is denied that a trust is in contemplation. The manufacturers claim that the business has been run on starvation prices owing to ruinous competition. The conference will last several days. Every wire mill in the country is represented."

PRICES OF COPPER.

The demand for copper is steady but by no means larger than close buying for immediate consumption and approximate necessities would warrant. In fact the output continues so large that prices may be expected to range below those recently obtainable. Lake Superior copper is quoted at 15 cents, but orders have been taken for delivery during the next month or two in medium quantities at 14¾ cents, and a shade less also.

MR. A. P. WRIGHT, of Boston, has sustained a very severe loss in the death of his mother in England, to which country he was called a few weeks ago by her illness. He has the sympathy and condolence of a host of friends in this great bereavement.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"Put Merit in your goods and Truth in your 'Ads.,'
So shall your purse not go lean."

THE EMPIRE CITY ELECTRIC CO.

Dey street has been startled out of its ordinary dinginess by the bright appearance that is made by the front of the large stores at 15 and 17, occupied by the Empire City Electric Co. The growth and development of this company has been rapid. In 1886 the concern was formed and took a modest store at 779 Broadway. Then finding, as business grew, that a removal down town was necessary, it stepped boldly into Dey street, and planted itself right in the very heart of the electrical supply district, with the big Western Union building in front and the handsome Telephone Building behind. The store was opened at 15 Dey, which soon barely sufficed, as it was found necessary to secure large store room in West street. For some time past, the further development of the business has rendered it desirable to give more space to the correspondence and accounting departments as well as more to the salesrooms; and with this object in view No. 17 Dey has been annexed, and an arched passage broken through the party wall, so that the two buildings are practically one on the street level. The new offices are as elegantly fitted up as those of a bank or insurance office, the walls being tastefully papered, while the partitions are of brass and light wood, and the furniture is rich and substantial. At the rear is a beautiful private office, with fireplace of special design. All the office work is done in these new quarters, while the large basement is devoted to the receiving and shipping departments. The Edison light is used throughout the spacious floors, and handsome chandeliers are now being made for the new offices. The Daft power circuits also run into the building. Besides the work done in Dey street the company also draws heavily on its manufacturing establishments at Adrian, Mich., and New Haven, Conn., for its stock, besides shipping direct from both those points.

As at present constituted, the Empire City Co. has Gen. O. E. Madden as its president; E. T. Gilliland, vice-president; H. G. Madden, assistant general manager; Fredk. Lines, secretary, and W. T. Black, Jr., treasurer. There is also a large clerical, sales and traveling staff, and Gen. Madden gives the business continually the benefit of his presence, advice and skill in organization.

TEST OF "INTERIOR CONDUITS" IN CHICAGO, ILL.

An exhibition test was made Dec. 20th and 22d before the architects of Chicago by the Interior Conduit and Insulation Co., of New York. The tests were conducted by Messrs. W. A. Willard and H. M. Underwood.

The exhibition embraced the following tests, viz.: 1st. Setting fire to a board by means of moisture where wires are run at regulation distance apart without blowing safety fuse in the circuit. This proves the ease with which a building can be fired should moisture get between the two conductors, if they are not placed in a tube or conduit, as the current will jump from one wire to the other.

2nd. Making same test with the wires in close proximity showing immediate action of safety fuse without igniting the wood. This test proves the safety of electric light wires, provided they are run in or inclosed in an insulating tube or conduit as at any one time there is not enough combustible material between the two conductors to set afire. This does not apply to mains conveying thousands of amperes, but to branches or taps only.

3d. Fusing a wire with rubber insulation, one piece running through the tube and the other wrapped around a fine strip; showing that electric fires are possible when conductors are not run in tubes. In this case the highest grade of rubber covered wire was used, the fine strip was fired after the insulation on the wire had been ignited, but the insulation on the wire which was in the tube remained partly intact, and did not fire the tube.

4th. Placing two wires in the tube connecting to a bank of lamps and fusing wire. This proves the high resistance of the tube against fire caused by the heating or overloading of the wires.

5th. Placing one wire in tube and the other wire in cap molding, setting fire to molding without injuring the tube, bank of lamps in circuit. This proves the superiority of the tube or conduit over all other methods of concealing wires.

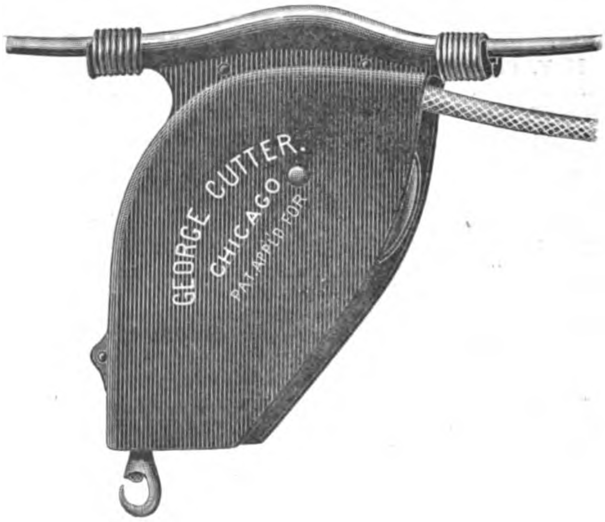
6th. Short circuiting flexible cord inside the tube without injuring it, showing that short circuits do not destroy or fire the tube.

7th. Short circuiting flexible cord outside of tube, setting fire to the insulation. This test illustrated one very common fault and the danger connected with it among users of incandescent electric lights, viz., the moving of a lamp supported by a flexible cord and hanging over a given point, to another position or point by driving a pin or tack through the cord itself and driving it into the plaster or woodwork. The instant the current was turned on, the cord parted and fired the insulation, showing that all pendants should be protected and run in a tube; in case a short circuit occur the fire is immediately smothered; in this case a pin was employed.

These tests were witnessed by a large number of the leading architects in the city, who expressed themselves more than pleased with the demonstrations and results.

CUTTER'S LAMP SUPPORTING PULLEY.

This ingenious device, which is shown in the accompanying engraving, is about to be put on the market by George Cutter, of 333 The Rookery, Chicago, and will meet the demand for a sleet-proof pulley which will support the lamp safely, even if the rope should get loose. The lamp is hung from a hook whose large knob is engaged by ridges, projecting from the sides of the pulley, which automatically support the lamp when raised, or release it again when about to be lowered. This is accomplished without the addition of any moving parts, in the manner shown.



GEORGE CUTTER.
CHICAGO
PAT. APPL'D FOR.

Fig 1.—Cutter's Lamp Supporting Pulley.

On raising the lamp the knob is guided by the raised ridges until it strikes the curved stop; then on slackening the hoisting rope, the knob is pulled down by the weight of the lamp into the recess in the lower corner of the pulley. The lamp is then supported entirely by the pulley, so that the hoisting rope may be loosened, or even cut, without letting the lamp fall. To release the lamp, it is raised until the knob has passed the corner of the upper ridge, when it will be guided out (as shown by the dotted lines in the cut) and the lamp can be lowered.

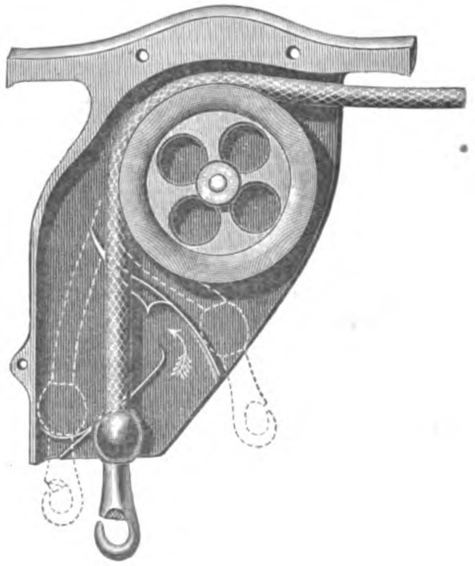


Fig. 2.—Interior of Pulley.

Both the engaging of the hook and the releasing are accomplished in turn by raising the lamp till the knob strikes a solid stop, and then slackening the rope. This leaves no time to be wasted in trying to stop at some exact point, or to disengage a series of interlocking cams, but makes the action as positive as it is simple.

The method of fastening the pulley to the suspension wire is also new and requires no bolts or screws to keep the pulley in its place. As the cuts show, the suspension wire rests in the grooved upper edge of the pulley and is held there by two wires wrapped around the ends of the pulley. The kink put into the suspension wire by this method of fastening effectively keeps the pulley from slipping along the wire, the more so as there is no tendency for this, excepting while the lamp is being raised or lowered.

That Cutter's lamp supporting pulley will adapt itself for use wherever arc lamps are used, is evident from its simple and ingenious construction; other uses in and about central stations will readily suggest themselves to station superintendents.

PAISTE'S PITHY POETRY.

H. T. Paiste, the well-known switch manufacturer, of 1201 Market street, Philadelphia, has issued a very pretty steel plate calendar, which like most of those coming from the decorous old city on the banks of the Schuylkill, has, as its chief ornamentation, the figure of a pleasing young girl. Why the Philadelphian taste runs that way, we do not know, but it is a gentle trait one cannot find fault with. Mr. Paiste is not satisfied with art, however, but has secured the following lines signed "J. R. H."—the familiar initials of James Russell Hawthorne:—

"At this gay season of good cheer,
Paiste wishes you a glad New Year;
Cannot you do for Paiste the same
And buy the goods that bear his name?
He wants your orders, please remember,
From now clear on to next December."

These lines should be pasted on the memory of every lover of true verse and buyer of good switches. At the back of the calendar are a number of "pointers" to hang it up with. The whole production is another evidence of Mr. Paiste's skill in advertising and of his business enterprise, confirming the impression he makes on the intelligent electrical public by carrying an effective card in every one of THE ELECTRICAL ENGINEER'S 52 Special Convention issues. The only reason why we do not care to hang this calendar in our office is that we want to take it home.

A FORETASTE OF THE NEW YEAR'S BUSINESS.

The Central Electric Company, 116 & 118 Franklin street, Chicago, recently received an order of remarkable magnitude from a western house for electrical supplies, the details of which aggregate some $16,000. A very large amount of Okonite and Candee wire is included in the order, which has already been filled in every particular.

U. S. ELECTRIC RAILWAYS CO.

This company, of 10 Wall street, has just issued a very neat and effective folder full of valuable information compiled by its general manager, Mr. L. W. Serrell, M. E., who has a peculiar knack of getting up in such shape just the little points that practical men want to keep in mind. This folder has a table showing the number and quantity of rails, spikes and splices required per mile of street railway track, with rails weighing 8, 12, 16, 20, 25, 30, 35, 40, 50, 56 and 60 lbs. per yard. Another page embraces a variety of figures as to electric railway operation, and of fuel and steam consumption. The whole is most tastefully printed and will slip into any ordinary pocketbook.

J. ELLIOTT SHAW & CO.

The above concern of 632 Arch street, Philadelphia, have just issued a large and handsome catalogue of the electrical goods they make and handle, a new price list of their electric bells, and a dainty little calendar shaped and colored like their well-known Norway iron frame bell. The house makes a great variety of electric bells, the gongs taking a number of special shapes and giving notes of uncommon richness, penetration, or pitch. In a pithy note or two on the subject, they say: "In the selection of electric bells for service, not only their first cost, but their lasting qualities should be taken into account. They should be so constructed that while the battery current is passing through the magnets, the armature carrying the striker for the gong should receive its full power, and when the contact is broken and the current ceases to flow, no trace of magnetism should remain. In the use of cast iron for the frame or case, cheapness only is taken into consideration, for cast iron having a hard surface, becomes magnetized to a certain extent after being in use a short time, thereby causing the movement to become sluggish, the bells become weak from no apparent cause, and additional battery does not remedy the defect."

CROCKER-WHEELER MOTOR CO.

The business of this company since its removal to Washington and West Fourteenth streets has seen a most rapid extension, and the C-W motor is now one of the best known in the country. The new shops are already filled up with the machinery necessary to keep the output in pace with the orders, and 1891 will see a further extension of their facilities. The company have lately been much gratified at the reception accorded their motor in England, from which country the orders are both numerous and large. Active preparations are now being made for the spring trade, which promises to be far in excess of that of last year.

CHRISTMAS TREE DECORATIONS.

A very effective display, according to the Binghamton papers, was made by Mr. F. J. Root, the local electrical supply dealer and contractor, at the First Presbyterian Church, where he lit up the big Christmas tree. He used thirty-one 16 c. p. Westinghouse lamps of assorted colors, connected in two circuits, so as to vary the colors at intervals, making a most pretty and effective result, upon which he received many compliments. Mr. Root handles all classes of supplies, from a door-bell to a dynamo, and also represents the Edison phonograph. He is building up a large trade.

HEYDRICKS & DUMARS.

The latest addition to the electrical business is the firm of Heydricks & Dumars, whose office is at the corner of Eleventh and State streets, Erie, Pa. The members of the firm are James D. Heydrick and H. T. Dumars, both of whom have been in the employ of the Erie County Light Company, and Mr. Dumars has been with the Keystone Electrical Company for some time. The firm are prepared to wire houses for electric lighting and put in all sorts of electrical apparatus. Both members are active young men bent on making a good record in electrical work.

MERCHANT & CO.

One of the very latest business brochures of the season is decidedly that issued by Merchant & Co., of Philadelphia. It is neither more nor less than a new "Brownie" book, not by Palmer Cox, perhaps, but certainly by a talented artist who can work in the spirit of the master. The sketches, of which there are a couple of dozen, illustrate the brownies handling electrical supplies, roofing, brass and copper tubing, sheet metal, ventilators, aluminum, nickel, tin, etc., cornice sheet metal, drawn and rolled German silver, etc., brazier's sheet copper, and a great variety of other things that the firm has long handled. The electrical sketches are particularly amusing.

CLEVERLY'S CHOICE CALENDARS.

We received a letter last week from Mr. H. A. Cleverly, of the Cleverly Electrical Works, Philadelphia, complaining mildly that he had sent two calendars for the adornment of our office and that we had not acknowledged the graceful compliment in good set terms or in any other fashion. On inquiring we found that one of our office boys who has a taste for the beautiful had been prompted by his æsthetic soul to keep those calendars remote from the editorial eye, and in the obscure and crowded recesses of the storage and mailing department. One of them has been rescued and we not only now give it this free and unsolicited advertising but have hung it in the editorial rooms, where he who would have his fancy touched by high art can see it any day between the hours of 9 A. M. and 6 P. M., Sundays excepted. We might also mention the fact that in sedate Quaker style Mr. Cleverly has adorned his letter sheets with the head of a very beautiful woman, the original of which probably sets the Philadelphian eye in a fine frenzy rolling—while we New Yorkers can only be humbly grateful to Mr. Cleverly for his generosity in placing her picture on his fine stationery so that we may admire at a safe distance.

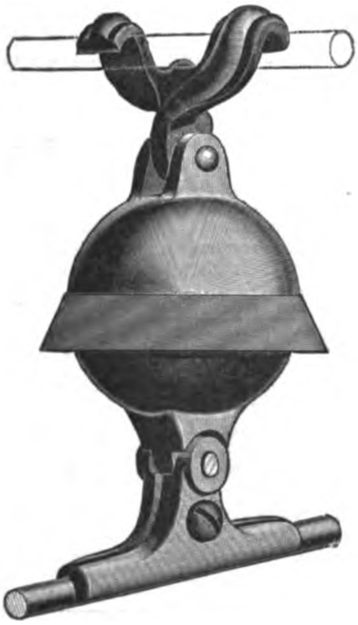
THE McCREARY ELECTRICAL SPECIALTY CO.

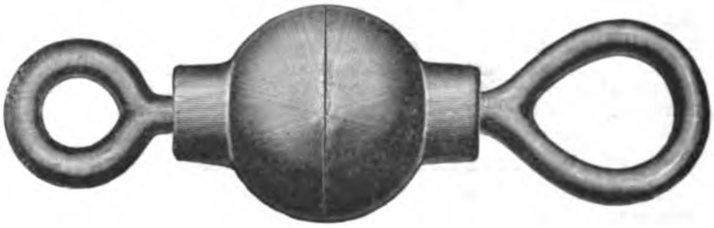
A new catalogue and illustrated descriptive price list has just been issued by the above company of 18 and 20 Cortlandt street. It includes all their well known and meritorious specialties and novelties, including the "Lancaster" switch and McCreary's flexible brass chain, the latter making a highly ornamental covering for flexible cord on all drop or pendant lights. It gives a most artistic finish to a fixture, and serves a doubly useful purpose, for if the cord be made a little longer than the chain, all the strain and weight may be placed on the chain, thus relieving the cord and enhancing its safety.

SOME NEW STYLES OF OVERHEAD INSULATORS.

THE illustrations, Figs. 1, 2 and 3, show a new range of insulators for overhead work, as manufactured by The Electric Construction and Repair Co., 205 and 207 Canal street, Chicago.

They are claimed to be exceedingly light and ornamental, and the main feature of utility is that all soldering is done away with. In the insulator for straight line work the insulation is obtained by a rubber piece half an inch thick, which is also made in such shape as to shed moisture, the form of the top or span wire clamp ensuring a perfect hold, and the bottom or trolley wire clamp giving a perfect hold on the trolley wire, yet at the same time not completely covering it. It is claimed that this insulator can be attached in one-tenth the time of those forms where soldering is required. The same recommendations apply to the curve insulator as are made on that for straight line work.





FIGS. 1 AND 2.—OVERHEAD TROLLEY LINE AND STRAIN INSULATORS.

The strain insulator is undoubtedly an excellent device, its strength being very great, and as will be seen, its shape is very neat and attractive. In all these forms the insulation is entirely concealed in the metal globes. The advantage of this feature can be readily appreciated. The cuts show the construction, which is as follows:—

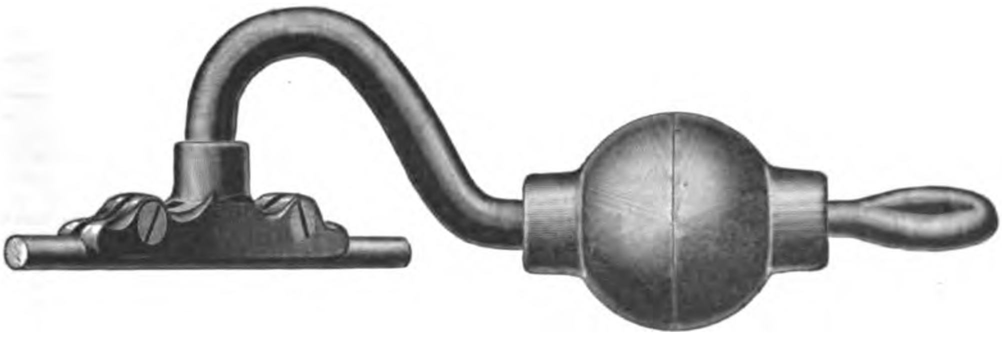


FIG. 3.—PULL-OFF INSULATOR.

No. 1 is made in four parts, top and bottom clamps and the two halves of the globe, between which is placed a rubber piece as illustrated.

No. 2 is made with the insulation, the eyebolt and the hook, on the inside of the globe.

No. 3 is made with the insulation the same as No. 2. In both No. 2 and No. 3 the iron used is made amply strong enough to meet all and more than their requirements.

The company have filed an application for a patent. The cuts shown are exactly half the actual size of the devices.

A NEW INCANDESCENT LAMP.

It is stated that the Great Western Electric Supply Co. are about to place upon the market a new incandescent lamp, which, it is claimed, possesses merits superior to all others.

THE CHICAGO ARC LIGHT CO.

The affairs of the company are said to be in splendid condition. The officers are: President, B. E. Sunny; vice-president, C. N. Fay; secretary and treasurer, C. H. Wilmerding. The directory is as follows: B. E. Sunny, C. N. Fay, Columbus R. Cummings, S. A. Kent, O. S. A. Sprague, L. H. Pierce and V. Shaw Kennedy. The same persons who were originally interested in the enterprise have continued with it, and it is said that some of them have considerably increased their holdings recently. Of the capitalization of $2,000,000 there is $1,230,000 of stock outstanding and no bonded indebtedness. It owns nineteen-twentieths of the stock of the Chicago Sectional Electric Underground Company, which controls the valuable franchise for the system of underground conduits under which the company operates, and has guaranteed 5 per cent. interest on the $260,000 worth of bonds issued by the company. The gross earnings of the company are about $26,000 a month; net earnings about $13,000. The operations of the company for the year ending April 30, 1890, yielded a gross return of $291,339.33, and the expenses were $186,596.90, leaving a net profit of $104,742.43. The business of this year is considerably in excess of last, and it is stated by persons who are familiar with the affairs of the company, that, judging from the present receipts, the net profits for the fiscal year ending April 30, 1891, will be $156,000. The company has so far paid quarterly dividends of 1½ per cent., the first having been declared January 15, of this year. Beginning with July, dividends are declared the first quarter.

THE AMERICAN ELECTRICAL WORKS.

Accompanied by a bright new one cent piece, done up in a small envelope in the left hand corner, the American Electrical Works issued the following Christmas card to its friends: "At this season of gift making and general good feeling we want to contribute our share to the festivities, and beg your acceptance of this slight token. Not knowing your personal tastes, and fearing duplicates of gifts, we send coin (legal tender) and urge you to spend it freely for whatever your inclination dictates, whether for art, insulated wires or tutti frutti. Gratify your wants fully; let Pleasure have her sway; but avoid foolish extravagance remembering that 'A penny saved is a penny got.'"

THOMSON-HOUSTON SALES IN THE WEST.

The Western Isolated Department of the Thomson-Houston Electric Co. has received the following contracts: National Distilling Co., Milwaukee, Wis., 100-light incandescent plant; St. Louis R. R. Co., St. Louis, Mo., plant for the cable power house, located at Broadway and Lami streets, of 200 incandescent lights capacity. They reported recently a sale to the same company for a 400-light plant which is now being installed at another power station located at Broadway and Salisbury streets.

HUNT ENGINEERING CO.

The above pushing and energetic young company moved on January 6 into their new offices at 238 Washington street, Brooklyn. They have rented the entire building, and before they get through will have ensconced themselves very comfortably and conveniently. The outlook for 1891, under the new auspices, is bright.

ANGLE AND BRANCH BLOCKS FOR SEELY'S FLEXIBLE MOLDINGS.

OUR readers are already acquainted with the very useful invention of Mr. John A. Seely, of this city, who has lightened the labors of the house wirer and at the same time increased the safety of wiring work by what is known as Seely's flexible molding. This molding is made by imbedding thoroughly insulated wire in a flexible composition, which not only adds to the value of the original insulation of the wire but allows of the same being run in the most inconspicuous manner and to take the curve or outline of every part of the room with ease and without injuring the insulation. The accompanying engravings, Figs. 1, 2 and 3, show in plan and section different sizes of this molding. Where it becomes necessary, however, to turn sharp angles, an angle block is introduced, which is shown in Figs. 4, 5 and 6. This block consists of two parts and is made of Mr. Seely's well-known composition, which is both insulating and fireproof, being made up largely of asbestos. The manner in which the flexible molding is applied is very clearly shown, one side being slightly cut down on each branch and connection made with the screws provided for that purpose. When the joints are completed the cover is screwed down.

When it is desired to take a branch from any circuit the branch block shown in Figs. 7 and 8 is employed. Fig. 7 shows the branch with the cover off and the cover below it. Here a somewhat similar proceeding as in the former case is applied, the manner of which is very clearly shown. Fig. 8 shows the branch block with the cover on. The application of the angle and branch block thus gives a complete system for the application of flexible wiring which has already met with much favor. These blocks are made by the Complete Electric Construction Company, of this city, manufacturers of the flexible wire molding.

BIG SHIPMENTS OF BELTING.

Passing by the store of Chas. A. Schieren & Co., Cliff street, one day last week, the attention of the writer was attracted by the shipments being made of belting. One of these belts was 150 feet long and 72 inches wide, and two were 48-inch double belts about 100 feet long; all being a second order from the Louisiana Electric Light Co., of New Orleans. There were also two 36-inch triple belts of the "Electric Perforated" type for a large iron works; a 54-inch three-ply for a large electric railway plant and a 41-inch three-ply for a big electric light plant. These belts made quite a display, and represented about $10,000—but the house was taking it quite as a matter of course.

PETTINGELL, ANDREWS CO.

There is nothing small about Pettingell, Andrews Co., of Boston, nor is there about the calendar they have just issued for 1891. It is big enough in fact, for two years, and owing to its size is intended chiefly for use outside the Bay State. We intend enlarging our offices, for the fifth time in nine months, so as to find room for this choice specimen of the printer's art, and have made up our minds that when we have leisure enough to sit down and figure out the percentage of growth of our circulation over what it was week before last, down to the tenth decimal, we shall borrow the type used in this broad sheet as the only kind big enough to do our increase justice. The calendars that he who runs may read we have long had with us—153 more of them arrived yesterday—but the calendar that can be read as you shoot past it in an electric express at the rate of two-and-a-half miles a minute is still the leading novelty of its class, and the electrical public has to thank the enterprise of Pettingell, Andrews Co. for it. May their sunshine and their calendars never grow less!

THE BREWER ELECTRIC RAILWAY CONDUIT.

In our issue of Nov. 26, 1890, we described the ingenious electric railway conduit designed by Mr. W. J. Brewer, of No. 115 Broadway, N. Y., in which the prominent features were the complete insulation of the working conductor and the simple method of construction of the conduit. Mr. Brewer reports that his system is attracting favorable notice from many quarters and that three street railway companies are now making a thorough examination with the view of adopting it on their roads. We may add that we have seen estimates of the cost of construction of the Brewer conduit which show that it exceeds but very little the cost of what is now recognized as the proper method of overhead line construction, so that the underground system is to-day well within the reach of street railway companies.

MR. C. D. SHAIN, general manager of the Eastern department of the Edison General Electric Co., was presented with a handsome diamond pin on Christmas eve by the employés of his department as a Christmas present and a token of their regard and appreciation of the kindness and courtesy he has always shown them.

B. & S. ELECTRIC EQUIPMENT CO.

This company has recently been organized, with offices at 115 Broadway, by Mr. E. T. Birdsall, M. E., and Lemuel Wm. Serrell, M. E., both gentlemen of large experience in the various branches of electrical engineering, and well qualified to see in advance the requirements of the electric railway and station manager. Mr. Serrell is well known as the designer of the present type of "C. & C. motors," besides being a prolific inventor in other fields. Mr. Birdsall was for several years with the Edison and other electric lighting and railway companies, and now enjoys an extensive business as a consulting engineer for electric railways. The company is putting on the market a line of electric railway pole-line apparatus which has been pronounced by several electrical engineers to be the best in design and efficiency brought out up to the present time. In addition, the company are selling agents for the Walworth iron poles, the American Circular Loom Co's "Canvas Jacket" wires and cables, the Russell arc lamp, etc. It will be the aim of this company to supply electric railway and lighting stations with appliances of a higher standard of excellence than it has been possible heretofore to obtain, and to design and manufacture improved high grade electrical appliances and fittings.

W. R. FLEMING & CO.

Messrs. W. R. Fleming & Co., 174 Fulton street, N. Y. City, agents for the Harrisburg "Ide" and "Ideal" engines, have closed contract during the past week for complete steam plant for North Plainfield, N. J., 50 h. p. The "Ideal" self-oiling engine to be used, and horizontal tubular boiler with Weitmeyer setting (patent furnace).

They have also taken orders from the well-known firm of Ketcham & McDougal, of York and Washington streets, Brooklyn, for 50 h. p. "Ide" engine to run an electric light plant which is to be installed by this concern.

"FEWER CARES" AND "INCREASED EARNINGS."

These are the twin mottoes that adorn the Season Greetings card issued by Alexander, Barney & Chapin, and they will go to the heart of every station superintendent who has been called up to locate a dead ground five miles out from home, in the rain, at 12:30 A. M., or has had his wires cut down and his rates for city lights cut up. The firm not only offer these mottoes to their friends but propose to adopt them for themselves.

THE PERRET MOTORS.

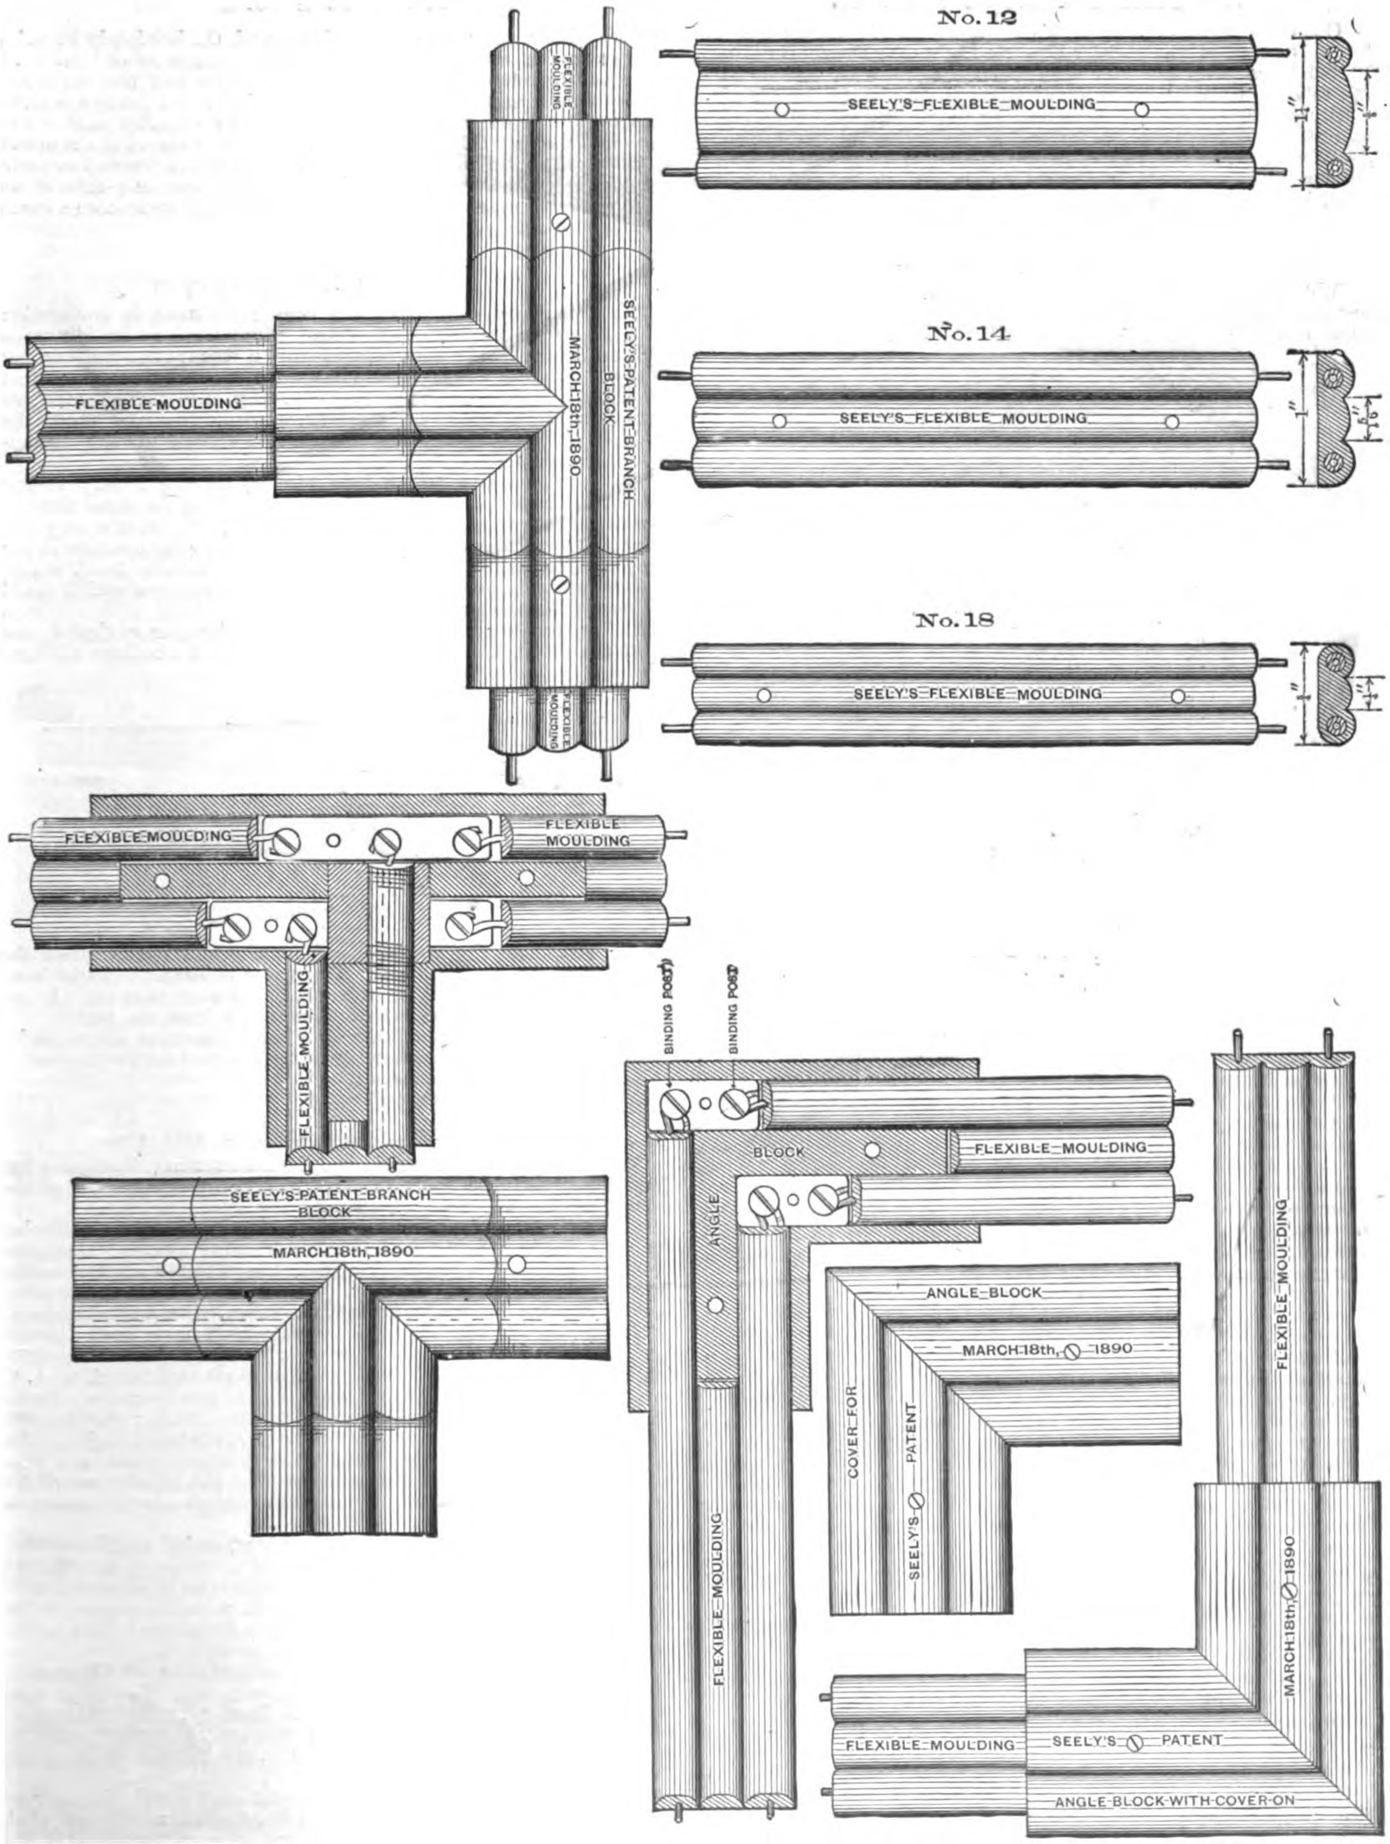
The Elektron Mfg. Co., of 79–81 Washington street, Brooklyn, have been sending out another batch of their excellent literature relative to the Perret motor. From their "List F." we extract the following interesting details as to sizes, speeds, etc.

Horse-power.	Voltage.	Approx. speed.	Diam. pulley.	Belt.	Weight. lbs.
1/12	2 to 10	* Has 3 speed switch.	1¼ in.	Round 1-8	13
1/12	4 to 10		1¼ in.	Round 1-8	13
1/8	12 to 110	2500	1¼ in.	Round 3-16	16
1/8	12 to 110	2500	......	....	20
[illegible]	20 to 110	2500	1⅜ in.	Round 3-16	25
¼	25 to 120	2000	2 in.	1 inch	50
½	25 to 230	2000	2¼ in.	1½ inches	70
¾	25 to 230	2000	2⅜ in.	2 inches	90
1	60 to 230	2000	4 in.	2 inches	155
2	60 to 230	2000	4 in.	2½ inches	200
4	100 to 500	600	8 in.	4 inches	500
7	100 to 500	600	8 in.	5 inches	700
10	100 to 500	600	10 in.	6 inches	900
15	100 to 500	600	10 in.	8 inches	1100
20	100 to 500	600	10 in.	9 inches	1250

It may be mentioned that in addition to their motors, the Elektron Co. handle rheostats, fans, Eaton ammeters, voltmeters and volt-ammeters; Deprez-Carpentier ammeters and voltmeters, and Kohlrausch's small spring ammeters.

STANDARD UNDERGROUND CABLE FOR FRANCE.

A special dispatch from Pittsburgh, of Dec. 27, says:—"The Standard Underground Cable Company of this city has secured a contract from the French Government for the erection of a plant with which to manufacture the underground cables for that republic. A. J. Waring left last night for New York to sail for Paris to begin the work. The French Government has determined to bury all the wires under its control. The plant which the Pittsburgh concern is to build will turn out about $1,500,000 worth of cable wire yearly. The same corporation is negotiating for the erection of similar works in Berlin."



Figs 1, 2, 3, 4, 5 6, 7 and 8.—Angle and Branch Blocks for Seely's Flexible Electric Moldings. (See page 28.)

THE HEISLER ELECTRIC LIGHT CO.

On page xxiv. of this week's ELECTRICAL ENGINEER will be found the card of The Heisler Electric Light Co., Drexel Building, Philadelphia, who say they wish to correspond with various parties relating to the distribution of agencies for the Heisler system.

Since this company determined to move and concentrate its manufacturing and sales departments in the East, General Manager Walter F. Smith has been busy night and day effecting the change. The company has greatly enlarged its manufacturing facilities, and will now push its apparatus on the market.

TESTED FUSE WIRE.

WE give herewith an exact reproduction of the certificate of test put on all reels of fuse wire tested by the Massachussetts Electrical Engineering Company, of Boston. The demand for an accurate fuse wire is so great that users of it will no doubt be interested to note the copy of the certificate, which gives the fusing point and safe carrying capacity, and to recognize the same when purchasing of their dealers.

CERTIFICATE OF FUSE WIRE TEST.

DAVENPORT FOUNDRY AND MACHINE CO.

A contract has been closed by the Davenport, Ia., Foundry and Machine Co. with the Berlin, Wis., Electric Light Co., for a 100 h. p. Meyer automatic engine, 60 x 16 boiler, heater and pump. They expect to have this plant in operation by January 20. The Meyer engine, which is rapidly finding its way into the electrical field, is the design of Mr. H. H. Meyer, the secretary and treasurer of the company.

CLINTON WIRE CLOTH CO.

The above company, of 137 Lake street, Chicago, with offices at New York and Boston, are manufacturers of wire netting of all kinds and grades, including that for the electrical trade. They make netting for rheostat boxes, dynamo polepieces, etc., and will furnish to any requirement.

UNION SWITCH AND SIGNAL CO.

The Union Switch and Signal Company, of Pittsburgh, has received the contract from the Pennsylvania Railroad Company to signal a new road at Jersey City. The same company has also been awarded the contract for the same kind of work on the elevated railroad extending from the ferry slip out to Shanley's Cut, a distance of three miles. The electro-pneumatic will be used, and there will be three towers and a number of 1,200 feet blocks equipped with electro-pneumatic track circuit block signals.

R. THOMAS & SONS.

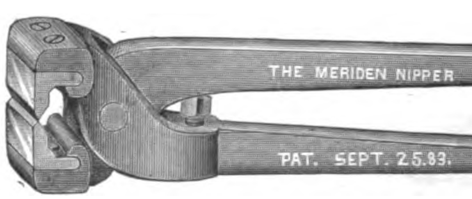
The above concern, of East Liverpool, O., has lately issued a very extensive and complete illustrated catalogue of its hard vitreous porcelain electrical supplies. They sell the porcelain only without screws or fittings. The body and glaze are alike composed of earthy materials. No lead or metallic oxides are used in the glaze. All the goods are fired with natural gas to about 4,000 deg. Fah. The first part of the catalogue is devoted to their general lines, the rest shows a number of special pieces made from models furnished by the originators. The back cover gives a view of the large works.

THE MERIDEN CUTTING NIPPERS.

There is perhaps no tool more frequently used in connection with electrical manufacturing and the wiring of buildings, as well as in connection with central station work, than the cutting nippers, and hence it is of the utmost importance that such a tool should at all times be in the best working order. To insure this Mr. Henry B. Todd, of Meriden, Conn., has designed the "Meriden" cutting nippers, which are shown in the accompanying engraving.

The aim has been to produce nippers having a very strong connection between the head and cutter, and at the same time so simple that the extra cutters can be furnished to fit, at a very low price. One of the principal features of the nippers consists in the simple manner of fastening the cutter to the handle head, which is at the same time one of the strongest connections which could be devised for the purpose.

The screw threads are tapped in the steel cutter so that a new thread is obtained with each new cutter, which obviates all danger of stripping the threads, as sometimes happens when the thread is cut in the iron head. The screw holes through the head are away from the joint of the nipper so that that part is not weakened by having the holes drilled into it from the top.



MERIDEN CUTTING NIPPERS.

It will be observed that there is a large clearance space under the cutters which makes them specially adapted for cutting wires of large diameter, sheet metal, etc.

THE WESTINGHOUSE RECORD FOR 1890.

The Westinghouse Electric and Manufacturing Company has just completed the most successful year in the history of the organization.

According to the report of shipments made up to December 31, 1890, the company shipped 217 alternating current incandescent dynamos of a capacity aggregating 248,150 sixteen candle power lights during last year. This makes a total of 730 alternating current incandescent light machines, with a total capacity of 720,800 sixteen candle power lamps, which have been shipped by the company since its organization in November, 1886. During the first year, i. e., 1886, the shipments amounted to A. C. apparatus aggregating 2,400 sixteen candle power lamps; during 1887 there were 106,200 lights; during 1888, 119,950; during 1889, 228,150, and during last year 248,850 incandescent lights. The figures prove the year just closed as the greatest record the company has ever made, and it also shows that the reputation of the apparatus manufactured by the Westinghouse company is constantly increasing.

During last year the company, however, added another branch to its business, in the manufacture of electric street railway apparatus. The company did not commence to ship motors until the first of July. Since then 211 15 h. p. motors have left the shops for the equipment of forty electric railways. This makes an average shipment of over 35 motors per month.

The company also commenced the manufacture of alternating current arc light apparatus during the last year. The first shipment of these machines was made in January, 1890. Since that time the company has shipped 107 alternating current arc light dynamos aggregating a capacity of 5,680 2,000 candle power lamps.

The Shallenberger alternating current meter and the converters utilized in connection with the Westinghouse system of alternating current electric lighting are now well known all over the globe. There are now over 20,000 Shallenberger meters and more than 30,000 converters in use.

During the month of December the company received orders to increase the capacity of seven central station plants where its alternating current system is already in operation, and, in addition, a number of new contracts were obtained for the installation of incandescent as well as arc light apparatus. Among the latest orders are: An increase of 750 lights for Olean, N. Y.; 3,000 lights for St. Louis, Mo.; 1,500 lights for Keokuk, Ia.; 3,000 lights for Louisville, Ky.; 500 for Wilmerding, Pa.; 750 for Mansfield, Pa.; 750 for Albion, N. Y.; 750 for Berlin Falls, N. H.; 750 lights for Windsor Locks, Conn., and 500 for White Water, Wis.

CENTRAL ELECTRIC CO.

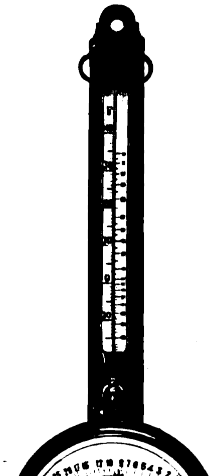
An unexpectedly large demand has arisen for the new Bain glass and break insulators recently illustrated in these columns. The Central Electric Company has just received its first stock order of these articles, and report that every insulator was sold before the shipment arrived. These insulators have a very practical appearance, and construction men speak highly of them.

Orders for Okonite and Improved Candee wires continue to flow to the Central Electric Company, and these standard articles seem to have no dull season, such as is expected in other lines of electrical supplies.

LAMBRECHT'S POLYMETER.

One of the neatest and most compact little instruments which we have come across is the "Polymeter," which combines in itself the means for determining no less than five most important meteorological conditions. It is frequently a matter of much concern to the manufacturer and more particularly to the central station superintendent to know the exact condition of the weather; and to be able to forecast it places him in a position to apply suitable measures to prevent interruptions in the service. The telegraph and telephone superintendent, likewise, when thus informed, is able to make suitable preparations which may prevent much annoyance and delay.

The instrument, which is illustrated in the accompanying engraving, embodies a thermometer, and below it a hygrometer, by means of which the relative humidity and the dew point or absolute humidity can be read off. In addition to this, the instrument gives the vapor pressure in millimetres of mercury and the weight of vapor in grammes in a cubic metre.



The Polymeter.

With such an instrument at hand the observer can easily make arrangements to meet the existing meteorological conditions as well as those which the instrument foreshadows.

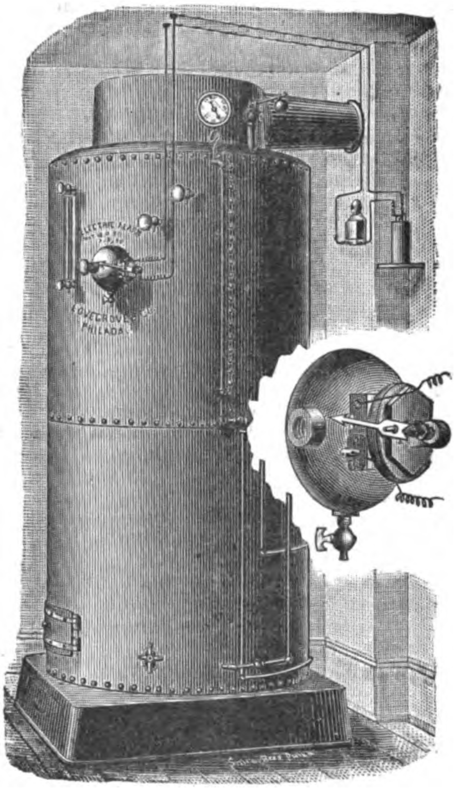
The "Polymeter" is made by Messrs. Gall & Lambke, of No. 21 Union Square, this city.

Mr. A. Langstaff Johnston, civil and consulting engineer, P. O. Box 43, Richmond, Va., is making a specialty of the construction of electric railways, a branch of work to which he has long paid attention. He announces that he is now in the field for any work of this class.

THE LOVEGROVE LOW WATER ALARM.

The accompanying engraving represents a new electric low water alarm for steam boilers, tanks, etc.

The alarm consists of a cylindrical casting which is attached to the boiler or water column by unscrewing the lower gauge cock and screwing in the alarm, after which the gauge cock is screwed in the casting and can be used as usual. The casting contains an improved float which is connected to the atmosphere through the stuffing box by means of the hollow rocker arm, to which the index is attached. This connection prevents the float filling with water and becoming inoperative. A vibrating bell is connected with the alarm, the circuit of which is closed by the float when the water sinks below the proper level. As a dry battery is employed in connection with the alarm, the latter requires practically no attention whatever. The device, which is exceedingly simple, is equally adapted for a high water alarm and is manufactured by Messrs. Lovegrove & Co., 143 N. 3d St., Philadelphia.



Lovegrove's Low Water Alarm.

ELECTRIC LIGHTING AWARDS IN PHILADELPHIA.

Awards have been made for street arc lighting, to eleven companies, at prices for overhead circuits from 32½ cents to 55 cents. Lights on the city underground circuits are 40 cents. The bids show a decrease of $23,000 to $25,000 in the total of the awards as compared with the previous year.

NEW WESTINGHOUSE PLANTS.

The incandescent electric light is rapidly supplanting the gas lamps out West. The Keokuk Electric Light and Power Company, of Keokuk, Ia., after having established a central station electric lighting plant of the Westinghouse alternating current system last year has just made another contract with the Westinghouse Electric and Mfg. Company for the supply of two dynamos; with this addition, the Keokuk plant will have a capacity of 2,250 sixteen c. p. lamps.

The Albion Electric Company, of Albion, N. Y., where an electric plant of five hundred lights has been operated about a year, is now compelled to increase its capacity. The central station is operating the Westinghouse alternating current system and the Westinghouse Co. has received an order for its apparatus of 750 lights capacity, which will immediately be installed at the Albion plant.

The Crosby Electric Co., of 87 and 89 South Fifth avenue, has issued a special circular announcing the fact that it has secured medals of superiority at the recent American Institute Fair for its Crosby dry battery, Hussey bluestone battery, Eclipse battery and Duplex battery.

NEW ENGLAND TRADE NOTES.

The Automatic Time Stamp Co., of 71 Sudbury street, Boston, have just sent out a very attractive catalogue of their new automatic "Employés' Time Register." This register is designed for automatically registering the exact hour and minute at which an employé enters the workshop, and consists of a clock and stamp, with a suitable receptacle for the reception of the ticket to be deposited by the workman. All a workman has to do is to take a ticket from a special delivery box, write his name upon it, put it into a slot in the register, pull a hook and all is done. The clerk, on opening the register, finds a ticket for each man employed, with an exact register of the time he entered the shop. The device is a good one and all employers of labor should procure a descriptive pamphlet as it is applicable for an infinite variety of purposes and the machine will save its price in a very few weeks.

The Samson Battery.—Colonel Burnham, of the Electric Gas Lighting Co., of Boston, in answer to a letter of inquiry as to the continued working of the Samson battery, has received a vast pile of answers, all of the most flattering description. The battery appears to have well borne out the early impressions of these users, and a few of the phrases in the letters may be quoted. "Best battery in the world," "Would not part with them, if I could not procure more," "Have never used or seen a battery that could equal it," "Too much praise could not be given it," "Improves with age," "Recuperation marvellous," "Gives perfect satisfaction, and have not heard the first complaint." A signal service man says he "finds it superior to any battery he has ever tried and considers it has no equal, has used hundreds and none have gone to the hospital." A telephone man says "it will rival anything in the market." Such good testimony should prove valuable, and keep the battery in the front rank of all open circuit cells.

The Pettingell Andrews Co., of Boston, have bought out the supply department of the business of F. M. Kimball & Co., of Boston, consisting of hanger boards, cleats, molding, etc., and repair parts for the various systems. The goods will still continue to be manufactured by Messrs. Kimball, so that exactly the same class of goods will be sold, but the Pettingell Andrews Co. will have the entire sale. The prices will remain as before.

Mr. George Cutter, of Chicago, was in Boston this week looking up his numerous friends, and arranging prospective agencies. Amongst his most recent arrangements, he has secured the agency for the West of the lamps of the Schaefer Electric Manufacturing Co., of Boston. Mr. Cutter's friends in the East wish him every success in his new venture.

The A. W. Harris Oil Co., of Providence, R. I., besides supplying large quantities of oil specially adapted for the lubrication of all steam engines, are having a large run on their electric dynamo oil, which is made specially to meet the requirements of quick running electric machinery, possessing great viscosity and endurance, and limpid and free feeding in automatic cups. Managers of electric light plants would do well to give this oil a trial.

Drake, Paysan & Whittier, Providence, R. I.—Mr. John J. Drake, of this firm, who unfortunately broke his leg about two months ago, is once more on his feet, and able to attend to business. Since September 1st this firm has installed in and around Providence about 2,500 lamps. They are doing first-class work only, and use only porcelain fixtures for cut-outs, switches, rosettes, etc., of the most improved type, all their work being done in such a manner as to be approved by the Board of Underwriters of New England.

WESTERN TRADE NOTES.

The Illinois Electric Material Co., Rookery, Chicago, the well known dealers in electrical supplies and specialties, are preparing a very handsome catalogue of the many goods and devices they deal in. They control some very unique and valuable specialties for electric light, power, and street railway work. The catalogue will be very carefully compiled, and will compare very favorably with any heretofore brought out.

Mr. G. A. Edward Kohler, hitherto the representative of the Eddy Motor Co., has given up his present position, and with the new year associates himself with The Illinois Electric Material Company, and will push their numerous supplies. I wish him the best of success in his new connection, and congratulate both Mr. Kohler and the Illinois Electric Material Company, whose already prosperous business he will, no doubt, widely extend.

Mr. Albert Scheible is now connected with Mr. George Cutter, at 333 Rookery, Chicago, and will assist him in his work in developing the many new and highly ingenious electrical specialties which Mr. Cutter is now busily engaged in placing on the market, and whose office as stated on his letter heads is becoming quite a "gravitation point" for articles electric.

The Central Electric Co., 116–118 Franklin street, are very active in all departments. The new Bain Glass insulators and Break insulators which they handle are meeting with unparalleled success, and the star of Okonite is ever in the ascendant.

Mr. Chas. T. Jaeger has ensconced himself at 200 E. Kinzie street, Chicago, where he will manufacture his new "Vacuum Pump" for exhausting incandescent lamps, which is meeting with such excellent success on account of the remarkably perfect vacuum obtained with it and its great simplicity and economy. Mr. Jaeger also pays special attention to "glass blowing" for all kinds of experimental and scientific apparatus of the most intricate and delicate character.

The Westinghouse Electric Co. have now got settled in their new quarters in Rooms 925–929 Rookery, Chicago, having moved from the ground floor into more spacious offices owing to their rapidly increasing business rendering more space imperatively necessary. The new offices are very handsomely finished and arranged with a view to comfort and facilitating business; and the benefits derived from the change will be apparent to all.

More Valuable Devices.—The Great Western Electric Supply Co., of Chicago, are constantly adding to their always large stock, specialties of known worth. They investigate all new patents and obtain the latest improvements in the electrical field. Their manager, Mr. H. K. Gilman, says that they will shortly introduce several specialties which are sure to have a very extensive sale.

Electric Railway Equipments.—The railway supplies of the Great Western Electric Supply Co., of Chicago, are of the most complete and comprehensive character. Their rawhide and fibre pinions are quite well known and giving first-class satisfaction. They are introducing a wood pinion that is destined to produce most excellent results, judging from the experiments thus far made.

The Great Western Electric Supply Co., Chicago, are doing a phenomenal business, and the demand for their well-known specialties constantly increases. The fame of this company's goods is rapidly spreading, as is attested by their latest order—a heavy railway contract from Germany. Those interested in electric and combination fixtures should not fail to see the magnificent line shown by the company at 190 Fifth avenue. Their stock is the largest in the West, and it is doubtful if the assortment shown can be equalled anywhere. The Great Western Co. are showing also a very fine and complete assortment of electric goods, suitable for birthday gifts. A toy motor and battery, or telegraph set, complete, makes an acceptable and instructive present for a child.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

THE
Electrical Engineer.

VOL. XI. JANUARY 14, 1891. No. 141.

THE INVENTORS OF THE ELECTRIC MOTOR.—II.

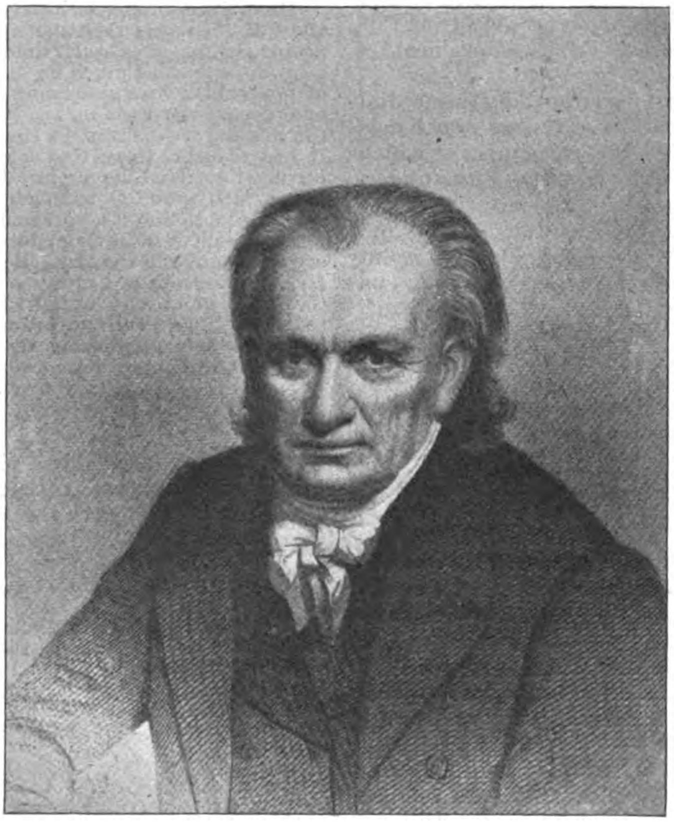
WITH SPECIAL REFERENCE TO THE WORK OF THOMAS DAVENPORT.

BY

Franklin Leonard Pope

ONE stormy day near the end of December, 1834, Davenport and Smalley drove over to Middlebury, taking with them their best machine, which they set up in a room at the village tavern. Davenport then set out to make the acquaintance of the Professor of Natural Philosophy at the college, and invite him to view the phenomenon. This part of the story shall be told in his own words:

> As I had never before seen a college or a professor, I rather dreaded making my acquaintance with those functionaries. I mustered up courage and walked towards the college. As I reached the steps of the building, I saw a fellow with a ragged coat on, an old rusty cap turned over his ears (for it was a cold, stormy day) and a large dirty plank on his shoulder, about entering the college at the same door as myself. I accosted him and inquired if I should be likely to find Prof. Turner about there. He said, "Yes, come in and I will show him to you." I followed him into a lumber room; he threw his plank down, pulled off his leather mittens and said "I am Prof. Turner; perhaps I don't look much like a professor." "As to that, sir," I replied, "I could not say, for you are the only professor I ever saw to my knowledge, but I conclude that your judgment don't lie in your clothes."



Amos Eaton

From a portrait painted by the late Abel B. Moore, circa 1841, and now in the Rensselaer Polytechnic Institute, Troy, N. Y.

Prof. Turner, after having received assurances that whatever the machine might be, it was not claimed to be a "perpetual motion," consented to examine it. The operation of the working model, as exhibited by Smalley, excited his enthusiasm to the highest pitch. He exclaimed :— "Gentlemen, what you have invented is indeed not a perpetual motion; it is nothing less than a *new motive power*, an electro magnetic engine." Prof. Fowler was at once sent for, and upon witnessing the surprising performance of the little machine, became no less enthusiastic than his colleague. In the presence of a dozen or so curious bystanders who had assembled, he made, as Mr. Smalley says, "a regular speech," in which he expressed in emphatic terms the opinion that those present were then witnessing the first exhibition of what would prove to be one of the greatest inventions of the nineteenth century.

Prof. Turner advised Davenport and Smalley to take immediate measures to secure a patent, and with characteristic kindness and generosity undertook to prepare for them a draft specification descriptive of the invention, which he recommended them to place in the hands of a competent attorney at Washington. This interesting document has fortunately been preserved, and the fac-simile of it herewith presented constitutes the best possible evidence of the stage of development which the invention had reached at the beginning of 1835, the date when it was written. This paper, which is in the handwriting of Prof. Turner, is in the following words :—

Davenport and Smalley's Specification of their Invention of an Electro-Magnetic Machine.

Middlebury, Vermont, Jan. 5, 1835.

The following is a description of the electro-magnetic engine invented by Messrs. Davenport & Smalley, of Brandon, Vt., and referred to in the accompanying application of this date. (See drawing below.)

A and B are horseshoe magnets, placed vertically around the axis *ab* to which they are fastened. Of these there may be any number almost; in the model which has been executed there are twelve, although for the sake of simplicity only two are represented in the drawing. It is to be observed that each pair of opposite magnets must have the same poles, as S S, uppermost: but that in case there should be more than one pair, the *adjacent* magnets must have their poles N and S alternately uppermost. C and D are galvanic magnets, or pieces of soft iron having copper wire wound around them, and susceptible of a high degree of magnetism by being connected with either pole of a galvanic arrangement. Q and R are galvanic batteries, consisting each of concentric copper cylinders with zinc between them. 1, 2, 3, 4, 5—16 are cisterns of mercury, of which 1, 6, 11 and 16 are connected with the zinc pole and 2, 5, 12 and 15, with the copper pole by means of wires *z* and *c*. The wires marked *x* connect 3 with 10, 4 with 9, 7 with 14 and 8 with 13. Y T and U V are two levers, turning on pivots at W by the motion of the axis *ab* and carrying with them transverse slips of copper with the extremities bent downwards. When the end Y of the lever Y T is depressed, these slips establish a communication between 9 and 11, 10 and 12, and consequently the wire *m* and the upper branch of C are connected with the copper pole of the battery, and the wire *n* and the lower branch of *c* are connected with the zinc pole. It is evident that, in this case, the upper part of C will be a north pole, and therefore attracted by the pole S of A, while the lower branch of C will be a south pole, and therefore attracted by the pole N of A. In consequence of this attraction the magnet A is brought nearly into contact with C when Y is raised and the end V of the lever V U is depressed; thus establishing a communication between 1 and 3, 2 and 4, or by means of the wires *x*, a communication between 1 and

> 10, 2 and 9, while the connection between 9 and 11, 10 and 12 is interrupted. Hence the poles of the galvanic magnet C will be reversed, the upper one will be south and the lower north; they will therefore be repelled by the corresponding poles of A. In this manner a rotary motion of the magnets A and B on the axis *ab* is kept up so long as the galvanic action continues in the battery. And in the same manner the influence of the battery on the galvanic magnet D or any others may be illustrated. With twelve magnets on the axis and two at the sides, the axis turns round about sixty times in a minute and consequently the poles of the galvanic magnet are reversed 360 times.
>
> To the axis *ab*, it is evident, that any machinery may be attached for the purposes of manufacture, propelling boats, cars on railroads, etc., etc. In the drawing the machinery is supposed to be applied near *b*. The action of the machine may be continued for any length of time by occasionally renewing the fluid.
>
> And on the other hand, the action may be checked or entirely suspended by raising part or all of the connecting wires *c* and *z* out of the cisterns of mercury.
>
> *Instead of the arrangement of magnets above referred to, it is thought that there would be an advantage in employing none but galvanic magnets either on the axis or at the sides.*

The significance of the closing paragraph will not escape the attention of the reader. It confirms the written description of Davenport and the independent verbal statement of Smalley, that as early as 1834 the conception of the combination of stationary and rotating *electro-magnets*, with a suitable pole-changing device, had been worked out and tried by them. The suggestion of applying electro-magnetic apparatus to the propulsion of railway cars is also worthy of note, inasmuch as it was not until fourteen years later that the steam locomotive made its advent in the state of Vermont. The Mohawk and Hudson railroad had, however, been in operation between Albany and Schenactady for some years, and it was probably from this circumstance that the suggestion in the specification originated.

The experimenters were greatly encouraged by the cordial reception which the invention had received at the hands of the Middlebury professors, and the warm interest which they had manifested in the further prospects of the undertaking. It is of interest to record that Davenport now for the first time obtained access to scientific books, from which he could gain some further knowledge of the agent which he was using. Among other works he was shown Silliman's Chemistry, containing accounts of some of Prof. Henry's experiments in electro-magnetism, from which, curiously enough, he first learned the proper names of the instruments and materials he had been using. Up to that time, having been ignorantly instructed by the people at Crown Point, he had called the battery the "cups" and the electro-magnet the "battery."

The difficulties which were inseparable from the use of the mercurial commutator when the rapidity of motion was great, have already been alluded to. Immediately after their visit to Middlebury, the experimenters constructed another machine, and correctly reasoning that the circuit might perfectly well be closed by a metallic commutator, as had been proven by touching of the wires together by hand, they substituted for the mercury contacts insulated segments upon the shaft, which were rubbed by contact-springs formed of elastic flattened wires, and were gratified to discover that this serious obstacle to the rapid revolution of the machine was now entirely removed. This improvement was made prior to May 1, 1835. It appears to be the earliest instance of the use of the modern commutator; an elastic contact-spring or brush, pressing against metallic segments, fixed upon a revolving shaft.*

Not long after the completion of this improved machine, a difference of opinion arose between Davenport and Smalley in respect to the most desirable policy to be pursued in disposing of interests and rights in the invention, in order to raise the funds to cover expenditures already incurred, and to provide the means which were urgently needed for the prosecution of further experiments, as well as for the procuring of patents. An amicable settlement was ultimately arrived at, in accordance with which Smalley relinquished his entire interest in the invention for a sum agreed upon, and Davenport was left free to seek for other assistance in the prosecution of his cherished designs.

For some months he continued his experiments, having for the time transferred the scene of his labors to Rochester, a small town a few miles east of Brandon, at which place, with the assistance of a mechanic named Richardson, he constructed no less than ten machines of different designs, some of which were capable of making 50 revolutions per minute.

The invention having now been brought to a tolerable state of efficiency, Davenport was naturally very anxious to lose no further time in securing his patent. In those days it was supposed to be absolutely necessary that the inventor should visit Washington in person in order to properly explain his ideas. At that date, 1835, this was a long, tedious and expensive journey. Being almost entirely destitute of means to carry out his design, Davenport appealed to his friend and neighbors, and succeeded, after many entreaties, in inducing six of them to make up a joint purse to supply him with funds for his intended journey to Washington. In July, 1835, he set out for the capital, carrying with him his latest model, and a letter of introduction from his friend Prof. Turner to Prof. Amos Eaton, who was at that time principal of the Rensselaer Polytechnic Institute at Troy, N. Y., as follows:

> MIDDLEBURY COLLEGE, June 4, 1835.
>
> DEAR SIR—I take the liberty of introducing to your acquaintance Mr. Thomas Davenport, the inventor of an electro-magnetic machine of singular interest. Mr. Davenport has labored long and expended much on his invention, but has not the means of prosecuting his experiments farther without the aid of some one possessed of taste for the science, and also of funds requisite for making a *fair* trial of the propelling power of his machine. It has occurred to me that could Mr. Van Rensselaer, of Albany, become interested, he might take pleasure in furthering an enterprise which promises so much; and in patronizing an American artist, who, it may be, will one day compete with Watt and Fulton in the glory of having added another prime mover of machinery to science and the arts. Being personally unacquainted with Mr. Van Rensselaer, I presume you will be so good as to do me the favor of introducing Mr. Davenport (by letter or otherwise) to that distinguished and estimable man. This or any other attention you can conveniently render, will be considered as conferring additional obligations on one who has the honor of being,
>
> Sir, your friend and fellow laborer,
>
> E. TURNER.
>
> Prof. AMOS EATON.

The Honorable William Slade, afterwards Governor of Vermont, who was at that time a member of Congress from the district, gave Davenport a note of introduction to the Commissoner of Patents, Hon. H. W. Ellsworth, from which the following extract is of interest as being indicative of his estimate of the man:

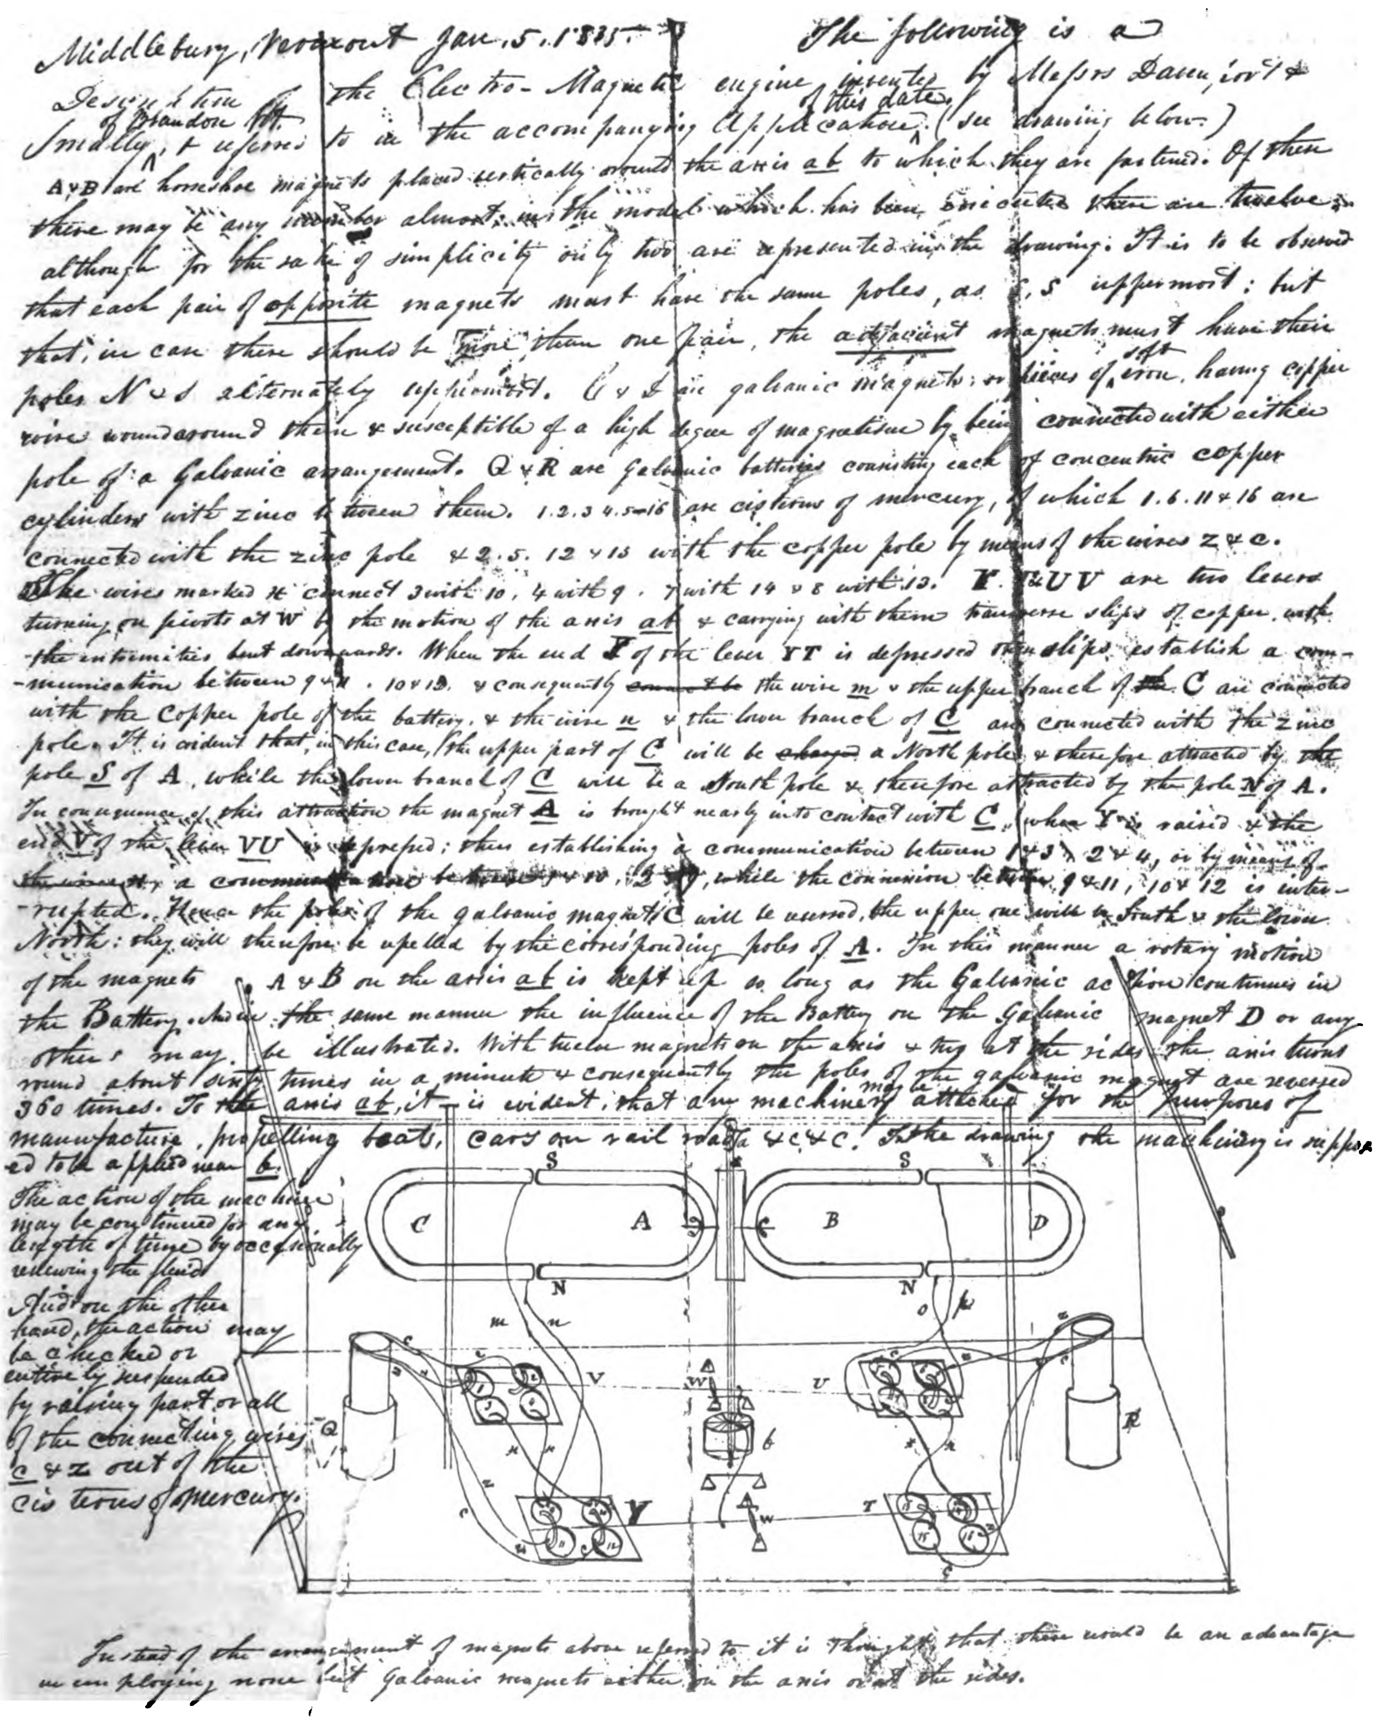
> The bearer hereof, Mr. Thomas Davenport, goes to Washington for the purpose of obtaining a patent for the production of motion applicable to machinery by galvanism. His diffidence has induced him to ask a letter to you, which I give with great pleasure. His personal worth is equal to his genius, of which he has given no equivocal evidence in the very ingenious machine for which he asks a patent.

Upon his arrival at the Rensselaer Institute, in Troy, Davenport was most courteously received by Prof. Eaton, who endorsed upon the note of introduction from Prof. Turner, a few lines recommending him to the consideration of General Stephen Van Rensselaer, the eminent founder and patron of the Institute, in which he said:

> I have told Mr. Davenport that no one could consistently aid him without Prof. Henry's approval. I have advised him to exhibit his machine to Prof. Henry, after you have seen it. This he will do. Professor Henry has suggested the practicability of applying this great power to machinery, but I did not from him understand that any plan had been fixed on. Mr. Davenport's plan is a simple and efficient one. . . . . It appears to me that Professor Henry would be greatly delighted

---

* By an error in copying, the foregoing sentence was attached to the description of Edmondson's apparatus, in p. 3 of the last number of THE ELECTRICAL ENGINEER, to which it obviously has no application.



Middlebury, Vermont Jan. 5. 1835. The following is a Description of the Electro-Magnetic engine invented by Messrs Davenport & Smalley, of Brandon Vt. & referred to in the accompanying Application of this date. (see drawing below.)

A & B are horseshoe magnets placed vertically around the axis ab to which they are fastened. Of these there may be any number almost. in the model which has been executed there are twelve, although for the sake of simplicity only two are represented in the drawing. It is to be observed that each pair of opposite magnets must have the same poles, as S, S uppermost: but that, in case there should be more than one pair, the adjacent magnets must have their poles N & S alternately uppermost. C & D are galvanic magnets: or pieces of soft iron, having copper wire wound around them & susceptible of a high degree of magnetism by being connected with either pole of a Galvanic arrangement. Q & R are Galvanic batteries consisting each of concentric copper cylinders with zinc between them. 1.2.3 4.5–16 are cisterns of mercury, of which 1.6.11 & 16 are connected with the zinc pole & 2.5. 12 & 15 with the copper pole by means of the wires z & c. The wires marked x connect 3 with 10, 4 with 9, 7 with 14 & 8 with 13. YT & UV are two levers turning on pivots at W by the motion of the axis ab & carrying with them transverse slips of copper with the extremities bent downwards. When the end Y of the lever YT is depressed the slips establish a communication between 9 & 11. 10 & 12. & consequently ~~connect to~~ the wire m & the upper branch of ~~the~~ C are connected with the copper pole of the battery, & the wire n & the lower branch of C are connected with the zinc pole. It is evident that, in this case, the upper part of C will be ~~always~~ a North pole & therefore attracted by the pole S of A, while the lower branch of C will be a South pole & therefore attracted by the pole N of A. In consequence of this attraction the magnet A is brought nearly into contact with C, when Y is raised & the end V of the lever VU is depressed; thus establishing a communication between 1 & 3, 2 & 4, or by means of ~~the wires x~~ a communication between 1 & 10, 2 & 9, while the connexion between 9 & 11, 10 & 12 is interrupted. Hence the poles of the galvanic magnet C will be reversed, the upper one will be South & the lower North: they will therefore be repelled by the corresponding poles of A. In this manner a rotary motion of the magnets A & B on the axis ab is kept up so long as the Galvanic action continues in the Battery. And in the same manner the influence of the Battery on the Galvanic magnet D or any others may be illustrated. With twelve magnets on the axis & two at the sides the axis turns round about sixty times in a minute & consequently the poles of the galvanic magnet are reversed 360 times. To the axis ab, it is evident, that any machinery may be attached for the purposes of manufacture, propelling boats, cars on rail roads &c &c. In the drawing the machinery is supposed to be applied near b.

The action of the machine may be continued for any length of time by occasionally renewing the fluids

And on the other hand, the action may be checked or entirely suspended by raising part or all of the connecting wires c & z out of the cisterns of mercury.

Instead of the arrangement of magnets above referred to it is thought that there would be an advantage in employing none but Galvanic magnets either on the axis or at the sides.

Fac Simile of Original Draft of Davenport's Patent Specification of 1835, For His Electric Motor.

with such a satisfactory exemplification of a principle which has extended his name to the ends of the earth.

Acting upon this suggestion of Professor Eaton, General Van Rensselaer gave Davenport a line of introduction to Professor Henry, which he delivered to him in person a few days afterwards at Princeton. Professor Henry was much interested in Davenport's machine, and after witnessing its operation asked how large a power he intended to build, to which Davenport replied "a full one-horse power;" whereupon Professor Henry, with his usual caution, suggested that it would be better if he were to continue his experiments for a time on a smaller scale. He said to him that if it were given out that he was building a one-horse power magnetic machine, and should he fail in his first attempt, which would not improbably be the case, not only would his credit as an inventor suffer, but the electro-magnetic engine would be hastily and unjustly stigmatized as a "humbug," a result which could not be but prejudicial to the advancement of science and the arts. Professor Henry, with the courtesy which he invariably exhibited towards deserving inventors, gave Davenport a certificate, in which he spoke highly of the novelty and originality of his invention. At the same time he did not hesitate to express to him the conviction, which he is known to have entertained even at that early day, that the application of galvanic electricity was at best an indirect way of utilizing the energy derived from the combustion of coal, and therefore could not economically compete with that agent as a means of propelling machinery. He nevertheless believed that it might be found useful in many cases in which the actual expense of power was a consideration not to be weighed against other more desirable objects to be attained. In his views in relation to this subject Henry was far in advance of most of his contemporaries, for the grand conception of the conservation of energy had at that day dawned only upon the minds of a few of the most profound thinkers of the period.

Before leaving Princeton, Henry exhibited to Davenport, much to the surprise of the latter, his oscillating electro-magnetic engine, made in 1831, of which an illustration has been given. This was to him the first intimation that any one prior to himself had even conceived the possibility of producing motive power by electro-magnetism.

While at Princeton, Davenport made the acquaintance of Professor Henry's life-long and intimate friend, Alexander Dallas Bache, then professor of natural philosophy in the University of Pennsylvania at Philadelphia, and afterwards for many years superintendent of the U. S. Coast Survey. At the cordial invitation of Professor Bache, Davenport accompanied him to Philadelphia, where about the middle of July he exhibited his machine in operation in the library of the Franklin Institute. While in this place it was examined with interest by a large number of scientific men. Prior to his departure for Washington, Professor Bache gave Davenport a letter, the conservative tone of which indicates that he had been led by his association with Henry to entertain similar advanced views in respect to the equivalence of the natural forces. This letter is as follows:—

> At the request of Mr. Davenport, I have examined a model of a machine applying the electro-magnetic action as a moving power. At first it appeared to me that an experiment might be made upon this model, from which the useful effects of a machine properly constructed might be inferred. But I am satisfied on examination, that such a result could be had only from a much more complete model than this, or from a working machine of full size. It would be highly interesting in a scientific point of view, and possibly in a practical light, if such an experiment could be made. The power is no doubt adequate to produce any effect which can be required in the arts, but the question of cost can hardly be fairly answered without experimental data.

>
> July 15, 1835.

Upon reaching Washington a few days later, Davenport discovered to his dismay that owing to the unforseen delays and expenses to which he had been subjected by his exhibitions in Troy, Albany, Princeton and Philadelphia, the added cost of preparing the drawings and specifications for his application for a patent would so reduce his available funds as to leave him without sufficient means to return to his home in Vermont. He was therefore compelled by sheer necessity to postpone for the time his intention of applying for his patent, and in a very dejected frame of mind set out for home, taking his model with him, Upon reaching Troy he proposed to sell his machine to the Rensselaer Institute for $30. Professor Eaton, favoring the proposition, gave him a line to General Van Rensselaer, recommending the purchase of the model. In attempting to enter the grounds of Mr. Van Rensselaer's mansion Davenport was set upon by three ferocious watch-dogs, who soon reduced his habiliments to a deplorable condition, although he was fortunately rescued by the servants before serious injury had been inflicted. Writing of this incident, he says:—

> **Mr. Van Rensselaer examined my certificates from Professors Henry and Bache, and the line from Professor Eaton, and meanwhile the kitchen-maid tacked together my torn garments.**

After receiving a check from General Van Rensselaer for the stipulated sum, and depositing his model in the Rensselaer Institute, Davenport returned to Vermont, in no very happy frame of mind. He had not only been unsuccessful in the main object of his journey, but had been brought like many others to a realizing sense of the fact that compliments are far more easily obtained than cash.

The model which formed the subject of this commercial transaction was preserved for many years in the cabinet of the Rensselaer Institute, but ultimately perished in the disastrous fire in Troy in 1862, in which the buildings of the Institute shared the fate of a vast number of others, and were totally consumed with all their valuable contents.

Professor Eaton, who was a man of a deservedly high scientific reputation, as well as of a somewhat enthusiastic temperament, had from the beginning conceived a warm feeling of friendship and respect for the modest and unassuming Vermont blacksmith, and exerted himself in every possible way to advance his interests. Scarcely had Davenport, dispirited and despondent, left Troy, when Professor Eaton penned the following flattering notice of his invention, and procured its insertion in a Troy newspaper. So far as can be learned, this was the first published notice of Davenport's electro-magnetic engine.

> [*From the Troy Daily Budget, August* 13, 1835.]
>
> An obscure blacksmith of Brandon, Vermont, 16 miles south of Middlebury College, happened accidentally to become acquainted with Professor Henry's discoveries in Electro-Magnetism. Possessing one of those minds which cannot be confined to the limits of a blacksmith shop—nor any shop less than the canopy of heaven—he applied this power to the astonishment of scientific mechanics. He turns three horizontal wheels around fifty times per second, with this power. The wheels and shaft weigh eleven pounds. He has convinced Professors Henry and Bache that the power is sufficient for strong machinery. A detailed account of it will appear in the next number of *Silliman's Journal*. The Hon. Stephen Van Rensselaer has purchased his first constructed machine (or model) for the Rensselaer Institute in Troy, as piece of school apparatus. No chemical or philosophical apparatus can hereafter be considered perfect without it. Whatever may be its fate in mechanics, it will cause the name of Thomas Davenport (the inventor) to accompany that of Professor Henry to the ends of the earth.
>
> Professor Bache, of Philadelphia, and Professor Turner of Vermont, have given their opinions in writing that Mr. Davenport's application of Professor Henry's discoveries may be made to move heavy machinery for useful purposes. According to their views, another Livingston might make another Fulton of the Brandon blacksmith.

A month later Professor Eaton wrote to Davenport at Brandon, enclosing a copy of the *Troy Budget* containing the article therein referred to. The letter and extract are as follows:—

[*Professor Amos Eaton to Thomas Davenport.*]

TROY, Sept. 9, 1835.

DEAR SIR:—I published a short account of your invention on the 13th day of August. It was copied into all the papers. Last week some mule of a fellow caused the *Daily Advertiser* to publish a statement that your plan "would not work." The New York papers and others copied it. While some gentlemen were trying to raise money to give you a chance for a trial, that rascally article stopped all exertions, and the subscriptions were burned; I felt it my duty to come out boldly for you, for the sake of my own reputation, and of Bache's, Henry's, and Turner's. You will see how I treat the subject in the *Troy Budget* of yesterday. My object in this letter is to tell you that you must be here about the tenth of October, and put your machine in perfect order; also you must exhibit it *yourself* at three o'clock p. m., on Wednesday, 14th of October, before a thousand spectators.

I will deliver a lecture while you are working it, explaining the principles, etc. The judge's seat in the court room is the place to show it. This small damper will, in my opinion, make your fortune. It will give you a chance to exhibit *truth.* I tell you TRUTH, TRUTH is everything! On that day (October 14) your exertion of your skill will make your fortune. Write me *immediately* telling me positively what to depend on. It is advertised in all the papers that your machine will be exhibited at three o'clock p. m., 14th of October next.

Your friend,

AMOS EATON.

[*From the Troy Daily Budget, September* 8, 1835.]

VERMONT ELECTRO-MAGNETIC MACHINE.

To GILES B. KELLOGG, Esq.,

It was through your agency that Thomas Davenport's astonishing application of Professor Henry's discoveries in electro-magnetism was announced to the world, and it is my particular request that you hasten before the public the following communication to the Albany *Daily Advertiser*, without waiting to copy it from that paper:

To the Editors of the Albany Daily Advertiser.

I have just read in the New York *Commercial Advertiser* the following extract from your paper: "We are sorry to inform our contemporaries that, on further examination, the plan of the Brandon blacksmith will not work." Knowing one of the editors of your paper to be a gentleman of true science and liberal feelings, I feel assured that he will contradict the unkind statement upon my assurance that it is totally untrue. Immediately after Professors Bache and Henry had examined this machine in brisk motion, the Hon. Stephen Van Rensselaer purchased it and placed it in my possession and care, but on account of the battery-cups having been injured in Philadelphia, it has not been put in motion since I received it. But I have often seen it in motion, and know it to be all that has been said of it—an astonishing application of electro-magnetism!

I have no interest in the invention; but, as the unaccountable falsehood which originated in your paper is calculated to injure an ingenious mechanic, I request you to publish this article.

On the 14th of October next, the electro-magnetic machine invented by a blacksmith in Brandon, Vt., shall be exhibited gratuitously, in the Court-house in the city of Troy, to all who may please to call, at three o'clock in the afternoon. It shall be in full action and shall be moved solely by electro-magnetism. It shall carry three wheels weighing eleven pounds, and a miniature trip-hammer, as an emblem of the inventor's avocation.

The fourteenth of October being the last day of the examination of students of Rensselaer Institue, many gentlemen of science will probably be present, to all of whom I pledge myself to demonstrate that the "plan of the Brandon blacksmith *does work*," according to the certificates of Professors Bache of Philadelphia, Henry of Princeton, and Turner of Middlebury.

AMOS EATON,
Senior Professor, Rensselaer Institute.

Davenport was at his home in Vermont when this letter reached him. His fortunes were apparently at their very lowest ebb. Day by day, for more than two years, he had labored indefatigably upon his invention, to the utter neglect of his ordinary means of livelihood. The heavy expenditures incurred in his fruitless journey to Washington had brought him to the end, not only of his resources, but of his credit among his townsmen. His father-in-law, a prosperous and well-to-farmer of Brandon; a shrewd and sagacious, though by no means illiberal man—albeit one who is reputed to have appreciated full well the value of a dollar—offered him every inducement he could think of to put aside his visionary schemes, resume his trade, and henceforth support his family in comfort. Other neighbors, who cherished a sincere friendship and respect for Davenport, joined in the appeal. He could not but be strongly impressed with their practical and common-sense view of the situation, and while in a frame of mind to comply with it, replied to Professor Eaton's letter, stating in effect that two years of incessant labor and anxiety had yielded him but scanty reputation and no money; that his credit was utterly exhausted, while his family were almost suffering for the ordinary necessities of life. Professor Eaton immediately replied, under date of September 21, 1835, deprecating in the strongest terms Davenport's resolution, and refusing to listen to his proposal to abandon the undertaking. Among other things he wrote:—

> Make my name Thomas Davenport, and I will give you five thousand dollars for your idea—rather, I mean "the bubble, reputation." . . . . It is a thing which will progress slowly; perhaps it may never yield you anything but reputation. But you have involved *friends*; and it is your duty to support their pledges for you. . . . Remember, if you fail to be here on the fourteenth, destruction is your portion!

This was the critical moment, the turning point, in the career of Davenport. Not only was the mere thought of throwing aside the hopes and aspirations which he had so long cherished almost unendurable to him, but his keen sense of honor instinctively revolted from the slightest imputation of bad faith towards the scientific friends who had cordially given him their countenance and support, or of reluctance to make good to the best of his ability, their pledges and expectations. On the other hand, to persevere was to be confronted with poverty, doubt, discouragement and almost with despair. To a man constituted like Davenport, however, a mental conflict waged on these grounds could have but one termination. Paraphrasing the memorable words of the elder Adams, he well might have exclaimed at this juncture in his affairs: "The die is now cast; I have passed the Rubicon. Sink or swim; live or die; survive or perish with my invention, is my unalterable determination." With renewed determination he cast aside all despondency and devoted every energy to his preparations for the demonstration at Troy. It is not easy for us to-day to appreciate the formidable difficulties with which he was obliged to contend. Brandon was at that date but an obscure country town, remote from all main lines of travel and transportation, the nearest city of any importance being Troy, N. Y., 100 miles distant, with which communication was maintained by stage-coach. He now determined to construct an entirely new machine, of a model adapted to railway locomotive purposes, and at once wrote to Professor Eaton to procure for him some necessary materials. In reply Eaton wrote on September 25, sending with the letter by a chance stage-coach passenger two packages of No. 16 copper wire, one of 3 and the other of 2 lbs.:

VILLAGE SCHOOLHOUSE AT BRANDON, IN WHICH DAVENPORT'S ELECTRIC RAILWAY WAS EXHIBITED. NOW PART OF RESIDENCE OF GEO. PARMENTER.

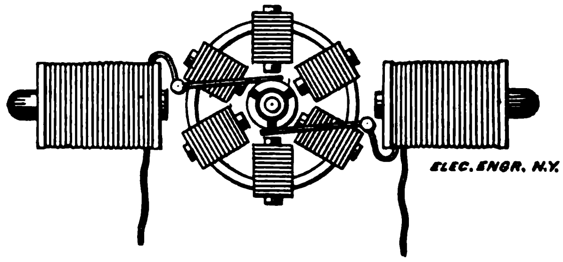
[*From a recent photograph by F. L. Pope.*]

Luckily I find Mr. Jackson (a neighbor of yours) at the stage-office. He promises to deliver you the wire. *I have broken all the hardware stores, and bought all the wire in the city*, and given it to Mr. Jackson.

Then came the difficulty of insulating the wire. Davenport had been led, from Henry's researches, to suppose that silk was the only material which would answer the purpose. But it was not only difficult, but in fact impossible to obtain this material in that remote region, and he was destitute of means wherewith to procure it from the city. But in this dilemma, the unselfish devotion of the faithful wife, who had loyally stood by him through prosperity and adversity, came to his rescue. Her one silk gown, the wedding dress which was her father's gift; almost her sole remaining relic of more prosperous but of perhaps not happier days, was bravely offered as a sacrifice to the cause of science. Cut into narrow strips, the treasured garment was used to insulate the helices of the new machine. Night and day the work went on with such success that punctually on the tenth of October Davenport presented himself at the Rensselaer Institute with the new motor in readiness for exhibition. On the 14th, pursuant to the pledge of Professor Eaton, it was put in operation on the Judge's bench in the court-room in Troy, in the presence of hundreds of interested and enthusiastic spectators.

Among the audience who attended this exhibition was a young artisan whose home was in Cabotville, a village just north of Springfield, Mass., which then enjoyed a high reputation, as indeed it does to-day, for the skill of its mechanics and the excellence of its products. This young man became greatly interested in the new motive power, and proposed to Davenport that he should immediately accompany him to Cabotville, promising to assist him to the best of his ability in bringing the invention into practical use. The proposal was accepted, and the two worked together at that place for some two months, during which time they completed a model of a circular railway 36 inches in diameter, upon which an electro-magnetic locomotive traveled with amazing rapidity. At the end of this time Davenport was informed by his associate that he was disinclined to go any further with the enterprise, but as Davenport himself says, he had little reason to complain of his conduct, inasmuch as he willingly gave him the benefit of two months' labor and his board during the time, to say nothing of some small expenses which had been incurred. It was now the middle of December and our inventor was again left in a state of destitution at a distance of 150 miles from his home. Hardly knowing which way to turn next, he bethought himself of a letter which he had received just before his visit to Troy from a silk manufacturer in Dedham, Mass., who desired to apply electro-magnetic power to the processes employed in his factory.

Among other acquaintanceships which Davenport had formed while in Cabotville, was that of a Mr. Kimball, himself an intelligent mechanic, who had taken much interest in the project of the electric railway. In his perplexity he consulted Kimball and was advised by him to take his machine to Dedham, and in case he failed to conclude a satisfactory arrangement with the silk manufacturer, to try a public exhibition of his circular railway in Boston, by which means he might perhaps raise sufficient funds to aid him in making further experiments. In addition to his good advice, Kimball very generously handed him $50 for his expenses, and not content with that, told him if his plans all failed to let him know, and he would cheerfully render him further assistance. "Such kindness," writes Davenport, "from a stranger whom I had never seen half-a-dozen times in my life, seemed to be an omen of future prosperity." He proceeded to Dedham, and although "received most politely" by the silk manufacturer, that person did not seem inclined to take any chances in testing the capacity of electro-magnetism for winding silk, nor did he offer to reimbuse Davenport for the expenses he had incurred in bringing his machine a long distance for exhibition. As a last resort the persevering inventor proceeded to Boston, hoping, as he says, "that the thinking portion of that intelligent city would be highly gratified with an exhibition of the wonderful effects of the silent, unseen and irresistible power of electro-magnetism." He accordingly exhibited his locomotive two weeks at the Marlborough hotel, and realized the princely sum of $12, just sufficient to meet the charges of his landlord for the use of the room. Davenport states that notices of this exhibition were published in some of the Boston newspapers of the day, but a diligent search through the columns of such journals as have been preserved has failed to reveal them. The exhibition, however, is well remembered by Thomas Hall, the veteran manufacturer of electrical instruments in Boston, who, although but a boy at the time, was employed in the shop of Daniel Davis, Jr., in which scientific instruments were made and repaired. According to the recollection of Mr. Hall, the machine consisted of a number of small magnets placed upon the rim of a vertical wheel, and constituting a sort of pole-armature, which revolved between the poles of two larger electro-magnets placed in a horizontal position which formed the field. His impression is that the field magnets were connected with the armatures in series. The current was supplied by a large Wollaston battery, and as the zincs became rapidly coated with oxide, necessitating frequent cleaning, two sets of batteries were provided, one of which was used while the other was being cleaned. The motor and battery were mounted upon a truck which traveled at a considerable speed.[*]



The Davenport Motor Exhibited in Boston, as Remembered by Mr. T. Hall.

At this juncture he received a letter from Kimball, cordially inviting him to stay at his own house for a few weeks and promising to furnish materials for building a larger machine. He accepted the proposal—there was obviously nothing else to be done—until finally, upon his expressing a desire to return to his family in Vermont, the generous Kimball furnished the dejected inventor with a new suit of clothes, and the necessary cash for his journey, and when in parting from him Davenport expressed his doubts as to ever being able to repay him, this good Samaritan cheerily remarked that he "need not trouble himself about that," but whenever he needed further assistance to call upon him.[†]

Writing of his circumstances at this time, in the early part of 1836, he says:

> For several months my prospects of getting assistance for a trial on a large scale, looked very dubious. My friends seemed to be worn out and tired of my talk about electro-magnetism being used as substitute for steam. Many hundreds of ingenious mechanics and wealthy people had seen the power propel machinery of various kinds, and all expressed a strong anxiety that I should persevere, and apparently wished with all their hearts that I might succeed. The great benefit it would have in saving human life was particularly mentioned by all who seemed to wish the project well, but yet I was totally unable to reach the purse strings of the capitalist. The objection urged by many was that my letters patent had not been taken out, and when I informed them that the patent could be obtained as soon as I could raise the

---

[*] The author desires to express his acknowledgments to William Lincoln Smith, S. B., of the Massachusetts Institute of Technology, and W. A. Hovey, of the American Bell Telephone Company, for making an examination of the files of the Boston papers, and to Mr. Smith especially for the information obtained from Mr. Hall.

[†] The author regrets that he has been unsuccessful in the attempt which has been made by him to identify the Mr. Kimball whose generous conduct towards a needy and struggling inventor, entitles him to the grateful remembrance of all electricians.

means sufficient for that purpose, the reply was that I had delayed so long already that some other person would probably anticipate me.

The necessities of Davenport's family now rendered it imperative that he should at once seek some means of livelihood. With characteristic persistence, he determined to attempt this by giving exhibitions of his circular railway and other electro-magnetic apparatus. His first entertainment of this kind was given in the public school-house in Brandon village. The occasion is well remembered by aged residents of that place who are still living. The building in which the exhibition took place now forms a part of the residence of George Parmenter, Esq., and, it may be remarked in passing, enjoys the further distinction of having been the school attended by Stephen A. Douglas, a native of Brandon, in preparation for college, he supporting himself meantime by working at the trade of a cabinet maker.

During the following summer Davenport exhibited his apparatus two weeks at Saratoga Springs, which even at that early day had come to be somewhat of a resort during the warm season for wealthy people from various parts of the country. While here he formed the acquaintance of a leading citizen of the place, the late Ransom Cook, who was at that time a prosperous manufacturer, and proprietor of an extensive shop driven by steam power and supplied with superior machinery and tools for working both in wood and metal. Cook was profoundly impressed with the apparent value and importance of the invention, and at once tendered to Davenport the technical and financial assistance necessary to bring his enterprise properly before the public.

THE POSTAL TELEGRAPH CO. NOT TO SELL OUT.

A statement has been published that Jay Gould had purchased a controlling interest in the Postal Telegraph Cable Company. This report is so far denied. One of the officials of the company says:

"The report is entirely unfounded. Our stock is not listed on the stock exchange and there is none to be bought. This company was formed for the purpose of carrying on a legitimate business and not for the purpose of compelling the Western Union to buy us out.

"During the past two years we have built more than 4,000 miles of line, and we are now pushing rapidly toward New Orleans. As soon as that link is finished our system will extend from the Atlantic to the Pacific and from the great lakes to the Gulf of Mexico. We have direct connection with the Commercial Cable Company and the Canadian Pacific Telegraph. The gentlemen who own a controlling interest in this company do not wish to sell, nor do the Western Union Company wish to buy our property, for they recognize the fact that should they gain control of our system a new company would be formed within three months."

THE NEW ELECTRIC LIGHT AND POWER STATION AT LOWELL, MASS.

BY

A. C. Shaw.

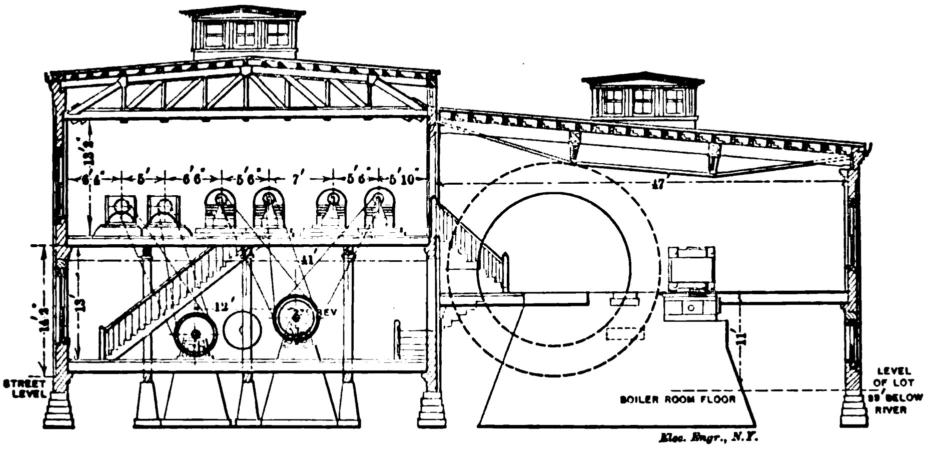


Fig. 1.—The Lowell, Mass., Electric Light Station.—Section of Engine and Dynamo Room.

No better proof of the commercial success of electricity as a producer of light and power can be adduced than the fact that so many cities are at last providing themselves with stations worthy of the name, and that engineers are giving their whole attention to the erection of stations which will not only produce the desired effect of making electric light and power reliable and popular, but which will be able to take care of the rapid increase of business, and at the same time have a chance of creating some dividend for the pocket of the stockholder. As another example of such a station, I take pleasure in presenting in detail the plans of the new electric light and power station at Lowell, Mass., which is now just being put into active service. Like most of the larger cities, Lowell has passed through an interesting history in the development of its electric lighting industry. The Lowell Electric Light Corporation was organized under the laws of Massachusetts, in 1881, with a capital of $10,000, and began business with two Weston arc light machines, leasing power from an accommodating sawmill. Business, however, did not thrive very well, and about a year later the Middlesex Electric Light Company was formed, and a small plant was built on Middle street. This company introduced the Thomson-Houston system, and shortly after effected a combination with the old company, under the same name, and continued to do business till about two years ago. At that time they reorganized under the name of the Lowell Electric Light Corporation, still continuing to use the Middle street station. Without going into details, it may be stated that they started at first with one 50 h. p. Armington and Sims engine, increased to three engines of the same manufacture, and then put in a 250 h. p. Harris-Corliss high pressure engine, remodelling the entire plant. Business continuing to increase, another addition was temporarily made, and then it was decided to build on an adjoining lot, and a 200 h. p. Atlas engine and another 300 h. p. Harris-Corliss engine were put in. In 1889, the alternating incandescent system was introduced, making an enormous increase in the demand for generating capacity, and a contract was entered into to furnish power for the Lowell and Dracut Street Railway Company, and it being at once seen that even the enlarged station was wholly inadequate to meet the requirements, it was decided to build a new first-class station, and accordingly land was bought on Perry street, near the river, where an abundance of water could be had for condensing purposes, it having been decided to adopt compound condensing engines, and build the plant on the most economical principles known. Their capacity at that time was about 800 h. p., and they were running about 450 arc lights, 2,000 alternating incandescent lamps, and 50 h. p. in stationary motors; and they were supplying current for from three to twenty electric cars. The new station is designed for 3,000 h. p., and 1,250 h. p. is being installed at present. The boiler room, as shown in the plan, is 66 feet wide and 92 feet long, and there is accommodation for 16 boilers 72 inches in diameter by 17 feet long. The boilers are built of steel and are of the horizontal tubular type, with 140 three-inch tubes, and were manufactured by Scannell & Wholley, of Lowell, Mass., and set by the Jarvis Engineering Company, of Boston, with their patent Jarvis setting. As will be seen, the boilers are ranged on either side of the room and the smoke stack is inside the boiler room. This stack is square in outside section, is 175 feet high, with a 7-foot round flue running to within 50 feet of the top. The floor of the boiler room is paved with brick, and the roof is supported by eight cast iron posts, supporting trussed beams, with two monitor ventilators. A light track will be led through the middle of the room, and a small truck will be used to bring in the coal from the outside storehouse, which will have a capacity of 1,000 tons, and which is in communication with the neighboring Boston and Maine Railroad. All the hot water pipes for feed water, communicating with the pumps, heaters and boilers, are of brass. The boilers will be fed by one Knowles pump, one Worthington pump and one No. 50 Hancock inspirator. The steam piping, furnished by the H. R. Barker Manufacturing Company, of Lowell, varies from 5 inches diameter over the first boiler to 14 inches diameter in the main steam pipe, and will be covered throughout to prevent radiation, Chapman gate valves being used throughout. On the wall between the boiler house and engine room is a Locke damper regulator, and a combination of Crosby steam gauges, etc. The engine room measures 140 feet long by 45 feet wide, and is connected by staircase with the boiler room. There is also an inclined plane connecting the two rooms, which is concealed under a removable part of the floor, which forms a great convenience for the handling of heavy parts of the machinery. Starting next to the boiler room wall, there is one 250 h. p. cross compound Harris-Corliss engine, with cylinders 16 inches and 30 inches diameter by 36 inches stroke, belting in to the extreme end of the counter shaft. Next comes a 200 h. p. Atlas engine to be used only in case of emergency, and which is the only high pressure engine in the station. Beyond this engine is a space for a 1,000 h. p. tandem Corliss engine (double 500 h. p.) for increase, shown in the engraving but not yet put in. Next comes a 500 h. p. tandem compound Harris-Corliss engine, built by the W. A. Harris Steam Engine Company, of Providence R. I., with cylinders 22 inches and 40 inches diameter by 48 inches stroke. The flywheel of this engine is 22 feet in diameter with a 52 inch face, is built in ten sections and weighs 50,000 pounds. The belt is 48 inches wide and was made by J. E. Gates & Company, of Lowell, who furnished all the belts in the station, both for the engines and dynamos. Space has been provided for another 500 h. p. Corliss engine, and lastly there is a 300 h. p. cross compound condensing Harris-Corliss engine, with cylinders 18 inches and 24 inches diameter by 42 inches stroke, belting on to the other end of the shafting. The floor is of the ordinary balloon construction with 12x12 inch Georgia pine stringers, supported on brick piers 30 inches square, on top of the stringers 3x12 inch spruce timbers 20 inches apart on centres, then a 2 inch spruce planking and finished with 1 inch birch flooring. There are no posts in the engine room, the roof being trussed with three monitor ventilators. The foundations of the engines are all of stone, no brick being used, as a very fine grade of stone is easily procurable in Lowell. The floor level of the room or cellar in which the foundations are laid is on the level of the lot, so that there really is no cellar nor excavation, making the room quite light, and convenient for placing of the air pumps, circulating pumps and other accessories, of the engines. The stone foundations extend about eight feet below the level of this floor. In their room are two Knowles condensers for the two smaller Corliss engines, and directly below the 500 h. p. engine is a Harris-Corliss condenser and air pump operated by a lever connected to the engine above. The exhaust steam of the large engine passes through a 500 h. p. National feed water heater, Fig. 3, manufactured by the National Pipe Bending Company, of New Haven, Conn., which will raise the feed water to over 200° Fahr. before entering the boiler, and then passes to the jet condenser. A valve is provided to allow the exhaust to pass into the air if required, instead of going into the condenser. National heaters are also provided for the other two Corliss engines, and brass piping conducts the hot water back to the boilers.

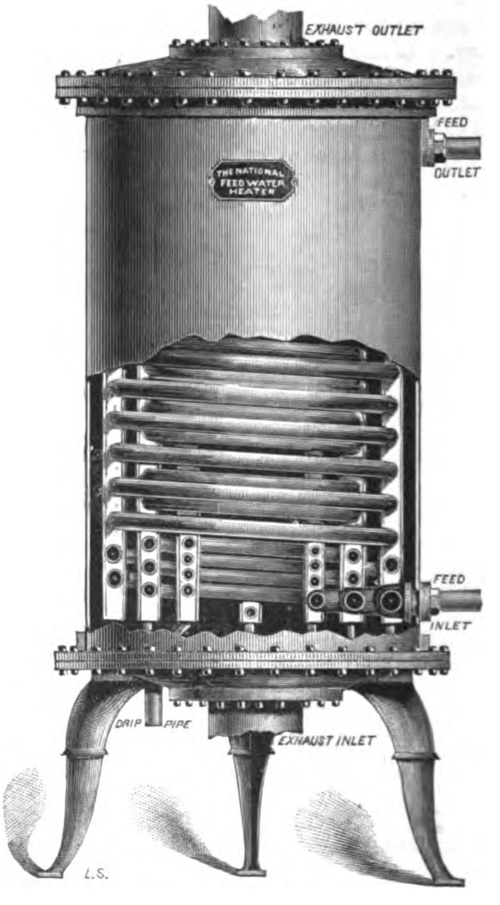

FIG. 3.—FEED WATER HEATER, LOWELL, MASS., STATION.

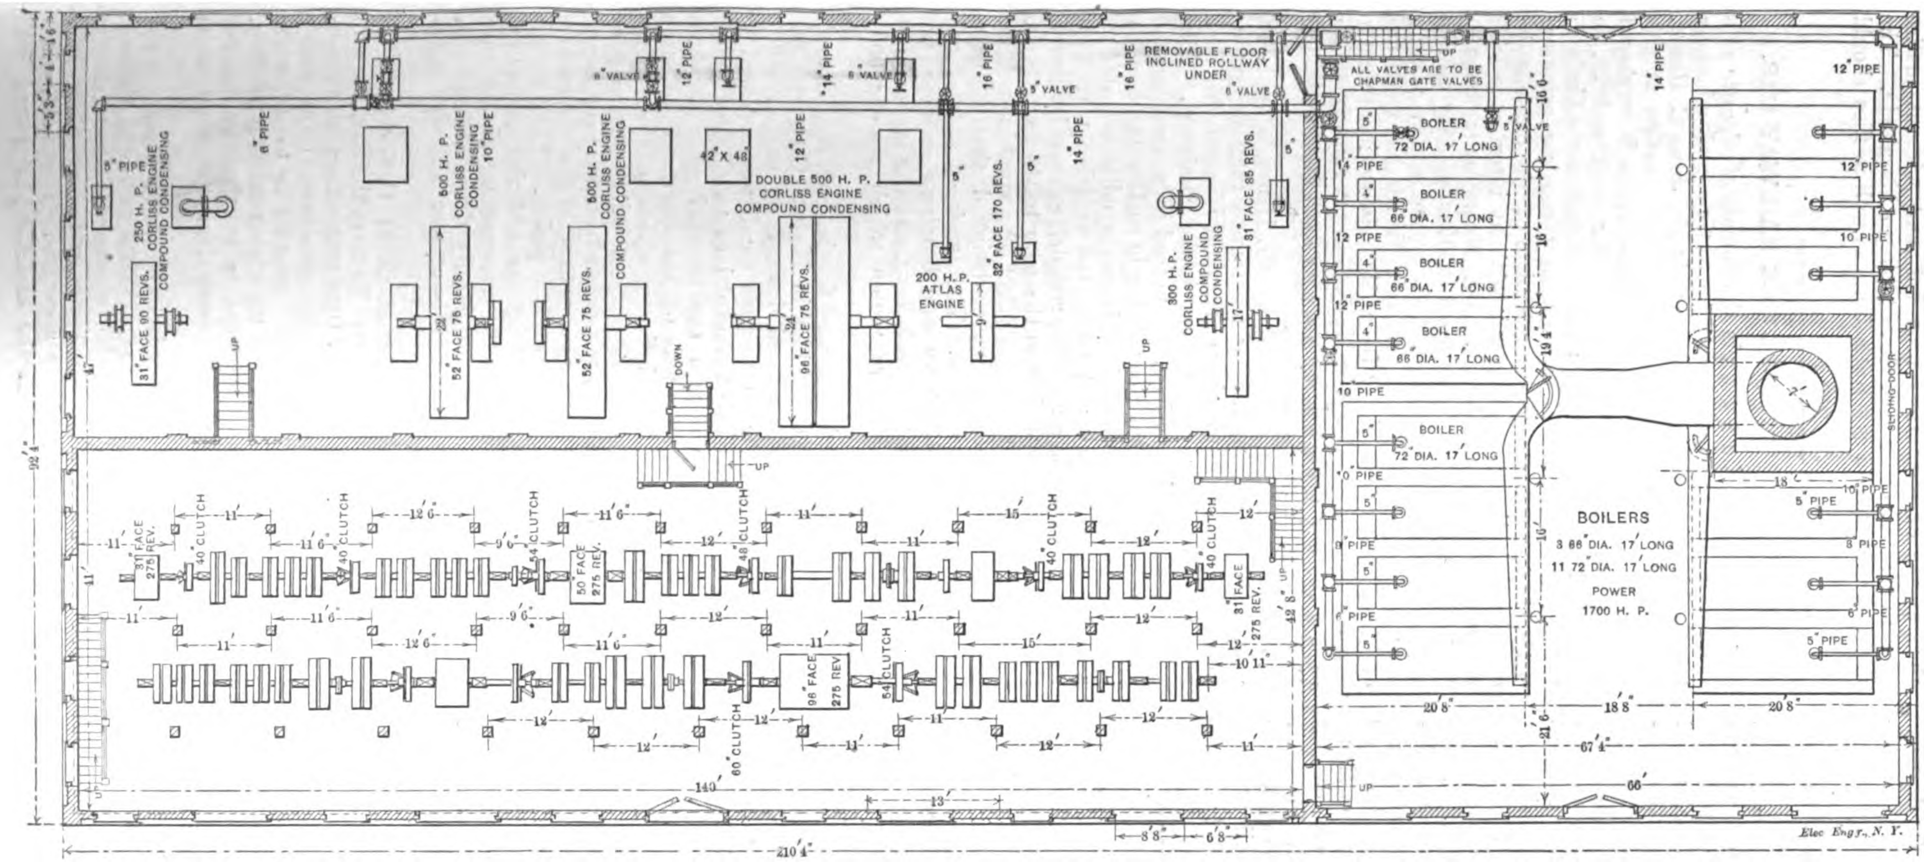
On the same level with the floor of the foundations of the engines, and on the other side of the building is the shafting room, which has been completely fitted up by Messrs A. N. Bates & Company, of 120 Pearl street, Boston. Special attention has been paid to make this shafting as perfect as possible, the very best materials and the best workmanship having been used. The foundations are of stone resting on a 12-inch bed of concrete made of broken stone and cement. The main journal bearings are supported on solid stone, and the other bearings on cast iron stands. The main pulley is driven from the 500 h. p. engine is 72 inches diameter by 50 inches face, and runs on a quill, so that the engine can be started without moving the shafting, and the strain does not come on the shafting. The belt from this engine passes under a heavy idler or



THE LOWELL, MASS., ELECTRIC LIGHT STATION.

FIG. 2.—PLAN OF ENGINE, BOILER AND COUNTER-SHAFT ROOM.

From the designs of Mr. H. C. Patterson, of the Thomson-Houston Electric Co.

belt tightener, manufactured by the Holyoke Machine Company, of Worcester, specially designed for this class of work. There are two Eclipse clutches, one 48 inch and one 54 inch diameter, on the quill, and there are four 40 inch Eclipse clutches, to subdivide the shaft into sections. The pulleys for driving the dynamos are of the slack and fast type, the slack pulleys running on special stands of the Holyoke Machine Company type, and not touching the shafting at all, the dynamos being provided with an extra wide driving pulley. The shafting is 6″ diameter and is made of steel, and no expense has been spared to make this part of the work representative in every detail. It may be mentioned that when the shafting was started up for the first time, it ran 17 consecutive hours, with a working load, without heating up in any way. The dynamo floor directly above the shafting room is supported by 33 12″x12″ Georgia pine posts. These support 12″x12″ Georgia pine stringers, with 4″x12″ spruce joists with 16″ centres, which in turn support 3″ tongue and grooved spruce flooring, which is then finished with 1″ birch. The dynamo room is 140 feet long by 47 feet wide. At the furthest end from the boilers, there is a small machine shop railed in, supplied with lathe and necessary tools for repairs, toilet room, bath room, men's room, and a small office for the superintendent, the executive offices of the company being in the city. On this floor there are 13 50-light Thomson-Houston arc light dynamos, two 50 h. p. 500 volt Thomson-Houston generators for stationary motors, four 100 h. p. Bentley-Knight railway generators, and two 1,300-light and one 1,000-light Thomson-Houston alternating incandescent dynamos. The arc dynamos are each set on hard pine base pieces, and the wall controllers are on the piers of the arched wall between the engine room and the dynamo room. The dynamo room is provided with a trussed timber roof with three monitor ventilators, two of which are used for wire towers. The station is wired throughout with okonite, furnished by the Pettingell, Andrews Company, of Boston, and almost all of the outside circuits are composed of P. & B. wire, manufactured by the Electrical Supply Company, of Ansonia, and supplied by the same company. The switchboards are all of the most improved skeleton type. The alternating board is arranged for three machines, with an extension to accommodate six; the arc light board is by itself, and a 500 volt board takes care of all the generators. Each room of the building is provided with stand pipe and hose in case of fire. The general design of the building is extremely neat and simple, and the whole building is well lighted throughout. As will be seen by looking at the sectional elevation, the engine room floor is six feet below the dynamo room floor and eight feet above the shafting room floor. Two stairways lead from the engine room to the dynamo room, one stairway from the engine room to the shafting room, and two stairways from the shafting room to the dynamo room. The wall between the engine room and the dynamo room is made of a series of arches, commencing on the level of the dynamo floor, with handsome moulded railing, so that anyone standing on the dynamo floor can see all that is going on both in the dynamo room and the engine room. The plans for the building were made by Mr. H. C. Patterson, of the Thomson-Houston Electric Company, and the whole work was carried out under the careful supervision of Mr. L. J. Fletcher, manager for the Lowell Electric Light Corporation, to whom my thanks are due for the foregoing details.

A NEW FORM OF METER REGULATOR.

BY

Alfred E. Braddell.

In the course of my duties while inspecting large numbers of electric light plants throughout Pennsylvania, New Jersey, etc., I come across many striking instances of derangement in the functions of electrical apparatus by purely accidental causes. When I say "accidental," I stretch the meaning of that word rather unduly, perhaps, for what we call accident is but too often the result of heedlessness, or carelessness, or the want of regular supervision. It stands to reason that apparatus which is closely watched, as all mechanism should be, is much less liable to get out of order and give trouble than that which is left to its own sweet will. Neglect quickly avenges itself in electricity as in most other things, and eternal vigilance is the price of steady dividends.

Some of these "troubles" that await even the most careful superintendent are very curious. I have just been given by the superintendent of an electric light station in my territory, a strange instance of the stopping of a meter, and of the explanation of its conduct. The meter in question was one of 20-light capacity. On going to read the instrument at the lapse of a month in order to determine, and charge for, the quantity of current used, he found that the consumer, in the pressure of business, had placed a mass of small boxes around the meter, concealing it from view. As it was desirable not to disturb them, it was suggested, and agreed to, that the meter be allowed to run another month. Upon the expiration of this time, the coast being clear, the meter was examined, and it was found that it had only recorded five hours during the whole two months.

This was suspicious, to say the least, but there was no ground to expect tampering, and so a very close inspection was made. It was then discovered that a spider had spun its web around the fans so that they could not rotate under the action of the current. It appears that the screw which holds the cover to the top of the instrument had not been put in, and, no doubt, the wily spider perceiving that he could secure a warm lodging free of rent, crept in through the opening thus provided, and without malice aforethought or otherwise, there took up his abode. The moral is that station superintendents as well as flies should beware of spiders.

THE NEW HENRY ELECTRIC RAILWAY CAR.

Among those whose work in the domain of electric railroading we have noticed from time to time, and who may be considered one of the pioneers, is Mr. John C. Henry. This gentleman's work deserves special mention at this time, not only on account of the original methods employed by him, but due to the fact that as far back as 1879, he advocated what is now again agitated and seems likely to become general, namely, a constantly moving armature with which the propelling mechanism of the car may be connected or disconnected at will without interfering with the motion of the armature. Mr. Henry as far back as 1884 operated an electric railroad in Kansas City on this plan and later in San Diego, Cal., a road which was in operation up to a year and a half ago. With the experience of his older work to draw from, Mr. Henry has recently become associated with the McKee street railway syndicate, and a car designed by him has been in operation at Rochester, N. Y., for some time.

The arrangements employed by Mr. Henry in his latest work are decidedly interesting from more than one standpoint, and the accompanying engravings illustrate his new motor truck and automatic car brake combined. The gearing, it will be noticed, is incased in a housing and runs in oil, the internal gear being in reality the housing itself. The single motor which is employed is mounted on a double swivel truck and connected positively to both axles, and by a single connecting rod, driven from its centre, the motion is transmitted from the gear to the car wheels.

The arrangement consists in effect of a combined motor truck and automatic car brake, so designed that the parts help to support one another. The truck consists of two cast steel frames which have side bearings on which the motor fields and armature shaft bear, and the arch shaped field magnets carry a centre pin on which the car body rests and swivels.

The gear employed is a modification of Mr. Henry's planetary gear as used by him in Kansas City and San Diego. The gear is mounted loosely on the armature shaft and inside of the housing is a small pinion keyed to the armature shaft. This pinion drives two intermediate pinions which engage with the internal gear A, which forms the housing. The pins of the intermediate gears carry with them an external disc E, which in turn drives the connecting rod from its centre. By clutching or arresting the internal gear, which is effected by pulling on the lever B, the intermediate gears turn on their own axes and around the axis of the armature pinion. This motion is transmitted to the connecting bar and the car wheel. When the clutch is released, the intermediate pinions turn freely on their own centres and only drive the internal gear A. In this position the car is at rest and the armature revolving freely.

The car is operated very much in the manner in vogue in cable railway practice. To start the car, the grip or clutch is applied gradually, thus preventing any abnormal current from entering the armature. On heavy grades, or with heavy loads, the practice is to allow the armature to revolve freely and the clutch to slip slightly, thus getting a yielding leverage in starting or hauling heavy loads; the motor at the same time operating at its best efficiency.

The armature of the motor is 18 inches in diameter and is of the Gramme type; it has a shaft 3 inches in diameter and is designed for about 35 horse power. The armature is wound with 500 turns of No. 7 wire, weighing 97 pounds, connected to 72 commutator segments. The field, which is connected in series with the armature, is wound with

No. 9 wire, having 90 pounds to each limb, thus making 360 pounds in all for the field. The construction is such that there are only two joints in the magnetic circuit. The armature is wound with one continuous length of wire, and loops are formed to receive the armature segments. The speed of the motor is regulated by commutating the fields and by slipping the clutch, as indicated above.

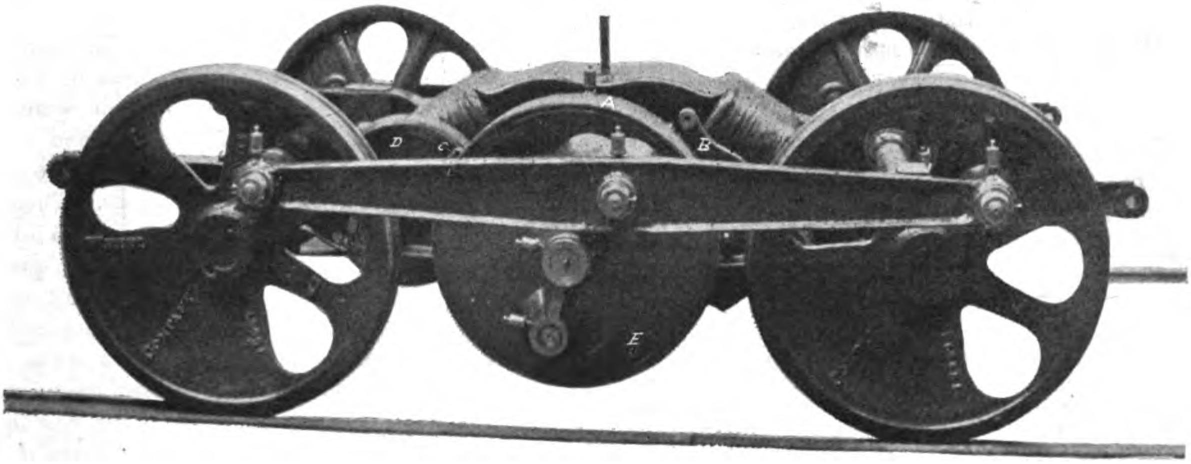


FIG. 1.—THE HENRY ELECTRIC RAILWAY MOTOR AND TRUCK.

The mechanical construction adopted is also worthy of notice. Thus the commutator can be removed in a very short time, as no solder is used in the construction of the machine. It will also be seen that by sliding the armature endwise on the shaft in one direction, and the fields on their supporting bars in the other direction, the armature can be entirely exposed and rewound or repaired without removing the field or taking it off its bearings. Both the car axles and the armature supports are $3\frac{1}{2}$ inches in diameter and are thus of great strength and stiffness.

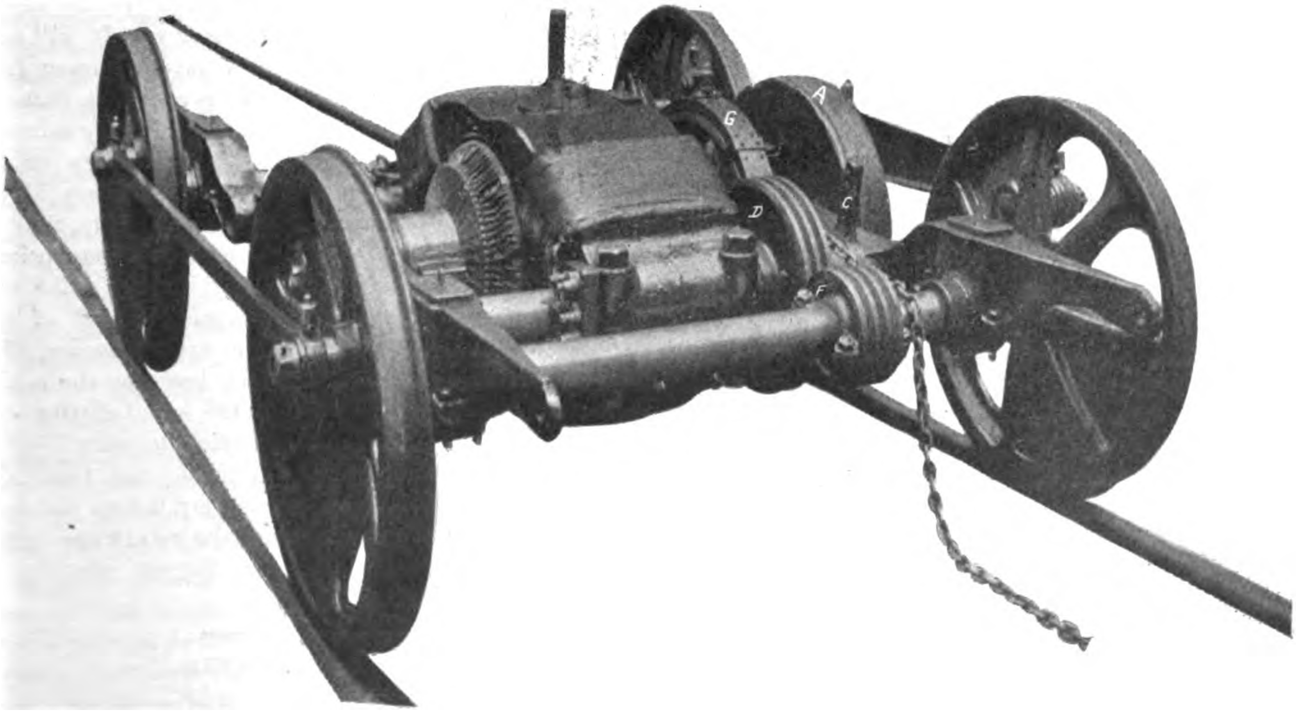

FIG. 2.—THE HENRY ELECTRIC RAILWAY MOTOR AND TRUCK.

We come now to another essential part of the arrangement, and that is the brake, which is supported by, and forms a part of, the motor truck. It is of the automatic type and consists of a V-grooved friction wheel F secured to the car axle, and a loosely mounted correspondingly V-grooved wheel D on the motor support. An eccentric operated by means of the lever C throws the wheel D in engagement with the friction wheel F and thus winds a brake chain which is connected to the ordinary brake shoes of the motor and to those of the trail cars. By this means the movement of the car is employed in applying its own brakes, thus relieving the driver of all severe exertion, the mere throwing of a lever similar to the one employed for throwing in the driving gear, being sufficient to apply the brakes. It will be evident that by disconnecting the driving machinery from the car axles it is much easier to stop the car, as the momentum of the latter need not then to be overcome in addition to that of the car itself, as is now the case. It will thus be seen that only two levers are employed which, under the control of the driver, perform all the operations requisite for the handling of the car.

The motor which we have just described was designed and constructed by Mr. Henry, and tested by the McKee syndicate with eminently satisfactory results. Owing to the constantly running armature and the small number of moving parts, as well as the thorough lubrication, the commercial efficiency has proved to be very high. The machine, although subjected to the most severe tests, has successfully stood the heaviest strains, and preparations are now actively going forward to introduce Mr. Henry's car arrangement on a large number of railways.

Let the imagination go, guarding it by judgment and principle, but holding it in and directing it by experiment.—Faraday.

ELECTRIC LIGHTING IN NEW ENGLAND.

WE publish in this issue another of Mr. A. C. Shaw's interesting descriptions of modern New England central stations. This illustrated series, which has attracted considerable attention, has brought out a number of points, and has shown throughout how remarkably inadequate all the early New England stations were. All of these enterprises began under humble conditions—Worcester in a basement, Lowell taking its power from an accommodating sawmill—and all soon found their equipment short of the necessities, until to-day, by successive and rapid strides, after having made frequent additions, they see that the best thing is to begin absolutely anew with such an outfit as the evolution of the art and the latest practice recommend.

In one or two previous discussions of this subject, we have dealt with it, chiefly and naturally, from the standpoint of the local lighting company. But another view of the case forces itself upon one's notice. A moment's thought will show that the great reason for these rapid extensions and rebuildings has been the immense popularity of the electric light in New England, where there are practically more local electric light plants than there are gas works. It is true that New England has from the first been canvassed with special energy by parent manufacturing companies with electric light apparatus to vend, and that the local managements have been very assiduous in pushing their business; but all this enthusiastic onrush would have been dulled and defeated were it not for the prompt appreciation that the New England public evinced toward the new illuminant. Besides, the New England stations, as a whole, have been peculiarly free from accident, and the rates have been moderate. Hence a desire to sell was seconded by a readiness to buy, so that the weird electric influences which according to Dr. "Joe" Cook have always been strongest in the north-easterly sections of this country, must have been marvellously intensified by the springing into existence of innumerable circuits and the daily distribution for light and motion of thousands of electric horse-power.

It seems to us, however, that New England is reaching a notable economical crisis in the progress of its electric light industry. We have recently been watching the annual addresses and reports of New England mayors to see if there were any trace of the movement towards the municipal ownership of electric light plants. There are not so many indications as we expected but enough to suggest the desirability of being ready to deal with the question, if private enterprise is to be stimulated and not quenched. One encouraging feature is that in every instance the electric lights are well spoken of, and that while in some instances the city councils are advised to go slowly in meeting the applications from citizens for new lights, in others an increase in the service or in the hours of lighting is suggested.

But the gravity of the situation, for those who wish to see more of these fine stations springing up in New England, is demonstrated best by the passage in the message of Governor Russell, of Massachusetts, wherein he proposes that towns and cities shall be granted more latitude than they enjoy now in regard to "municipal control of municipal work and ownership of the instrumentalities for its performance." Our New England friends should be preparing themselves for the emergency. It will be a fight not for their modest dividends but for human freedom, and for the abstention of the government, State or municipal, from every unessential duty and every unnecessary tax. It is an amusing, but sad, commentary on the situation referred to that in New York city, where Mayor Grant has also been proposing municipal ownership, the only decent street cleaning is that done by the citizens' private enterprise, and that in Baltimore, which also talks of a municipal electric light plant, a company formed of local business men has offered to do the street cleaning effectively for $175,000 a year or $100,000 less than the municipal establishment costs. But then the new lighting plant will provide $20,000 worth of new offices to control politically, so Baltimore's practical politicians and theorizing professors, with intermingled tears of joy, hasten to help in setting up another tyranny. Thus are we always signing Declarations of Independence and forever placing our neck under new yokes.

TELEPHONE RATES.

UNDER the above heading our estimable contemporary, *The Electrical World*, takes occasion to admonish the Metropolitan Telephone Co., and by implication the managers of the telephone service in other American cities, in the matter of charges. Results of the service under government administration in Germany, particularly in Berlin, where the annual rental to subscribers is given as 150 marks, about $37.50, and where the service is said to be fairly satisfactory, are offered to justify a note of warning to the American telephone companies of the possible adoption of a government postal telephone system to supply the public cheaper and better service. After noting the establishment of telephone communication between Berlin and Bremen, at charges "from 25 to 50 cents *per message*," *The Electrical World* makes comparison with the rate between New York and Boston for *five minutes conversation*—which it mistakenly states as $2.50 instead of $2.00—and says "the rates now charged could be much reduced and the business would still yield a good profit, at least what would be considered a good profit in any business that does not partake of nature of a gigantic monopoly."

This expression of opinion seems infelicitous, both in its inference from the German figures and in its indirect attack upon property in patents.

As between this country and Germany, even if there existed an equality of conditions and a parity in the quality of the telephone service, no legitimate conclusion as to the equity of the German rates could be drawn in the absence of a balance-sheet showing how much profit or loss attends the administration of the telephone service—whether any deficiency falls upon the tax-payers. The subscriber's rental of $37.50 prevails not only in Berlin and other large cities, but throughout Germany, in small towns and great. We have trustworthy information that the Berlin service is conducted at a very considerable annual loss; the deficiency must be made good from taxes, or, which comes to much the same thing, or worse, from any profit that can be derived from the service in much smaller towns. The uniform German rental is about equal to the lowest rate charged in this country—in the small towns and villages. After deducting royalty, a charge not incurred by the German administrations, the American local company supplying service at $36.00 or $42.00 per year in small towns gets less than the German rate.

We shall not here point out the several marked differences in conditions touching such an industry as the telephone service in Germany and the United States, such as a ratio of about 1 to 3 in the wages of operators, nor dwell upon the persistent and intelligent efforts and vast expenditure that the leading telephone companies, including the long-distance company, are devoting to the provision of improvements in construction and apparatus and the amplification of facilities for the public. Our larger exchanges, as New York, Boston, Chicago and Philadelphia, are pushing forward the execution of well considered and far-reaching plans for underground wires with general systems of metallic circuits, and bringing to bear upon them the most advanced knowledge and practice of the art of the telephone engineer, and at a cost that would be a revelation to that thoughtless portion of the public—happily lessening, we believe—who deem the telephone companies oppressive in their charges and indifferent to the quality of their service. We do not think that any considerable number of the people who use telephones want the service in part at public expense, much less at the expense of other subscribers in different localities. No paternalism is wanted here; paying for what one gets is still the preferred way.

Our contemporary's use of the term "gigantic monopoly" is to be deplored for its implied assault upon patent property. Our readers do not need to be reminded that in its very nature and essence a patent bestows upon its rightful owner exclusive use and control of an invention for a definite period of time; nor do they need to be told that the rewards possible under the rights conferred upon inventors by our patent laws have been a chief factor in stimulating the achievement of our industrial prosperity. If a patent be in a proper sense a monopoly, "it is not," as a distinguished judge once said, "an odious monopoly." The distinction between patents and monopolies has never, perhaps, been better presented than in the following words, from the opinion of Justice Giles, in the sewing machine case, Singer vs. Walmesley: "Patents are not monopolies, because a monopoly is that which segregates what was common before, and gives it to one person or class for use or profit. A patent is that which brings out from the realm of mind something that never existed before, and gives it to the country."

THE ART OF ELECTRO-DEPOSITION.

Electro-deposition of pure copper from copper matte has already assumed such proportions in this country, and the indications of its large growth in the future are so unmistakable, that the exact conditions involved in work of this nature ought to be generally known, so that the greatest possible economy in the working of the process may be obtained. Up to the present time this class of work has been confined to but comparatively few firms, who have for the most part kept their methods secret, and though the general principles are well enough known, the details are by no means matters of general knowledge. Judging, too, from recent publications abroad, there is a decided lack of knowledge there on certain important points in connection with the process and especially upon the best method of the arrangement of the vats. Our readers will therefore find in the article by Mr. C. O. Mailloux a succinct and accurate statement as to the factors governing many important points in electro-deposition, and the conditions to be fulfilled in order to attain any desired result. Mr. Mailloux's statements being based upon the results of his own actual practice and personal experience, are worthy of the closest attention, and we hope they will set right any misapprehension that may now exist on the points involved.

Electric Railway Underground Conductors.

To the numerous plans which have been proposed for running electric railway conductors so as to avoid the necessity of using overhead wires, we add this week another, due to Mr. F. Mansfield, by which the inventor hopes to meet some of the difficulties which our rigorous climate imposes upon such a system. Having in mind the fact that the accumulations in a conduit may easily become of such a nature that their removal is practically impossible through the ordinary channels provided for the drainage of the conduit, he proposes a system in which that contingency is met with by running an insulated conductor below the surface and connecting it at regular intervals with the device which is closed mechanically by the car in its passage over the road. The manner in which the details of the system have been worked out by Mr. Mansfield is decidedly interesting, and it is to be hoped that an early opportunity may be found for giving the system a practical trial.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—IX.

(*Copyright, The Electrical Engineer.*)

BY

Herbert Laws Webb

TEST FOR INSULATION.

THE connections for the insulation test are shown in Fig. 30. It will be seen that almost the only difference between this and the preceding diagram is that the cable takes the place of the high resistance. In taking the galvanometer constant, however, it makes no difference whether one side of the battery key and high resistance are put to earth or connected directly together,* but in making the test for insulation one side of the battery must, of course, be put to earth, as it is the dielectric of the cable that really takes the place of the high resistance and the dielectric is in contact with the earth in the natural course of events.

Before the cable is connected to the lead the instruments and lead should be tested for leakage by turning on the the full battery power and opening the short circuit key, no shunt being inserted in the galvanometer circuit. If any deflection is observed it should be noted under the heading of "leakage from lead," and the amount of this deflection should be deducted from that given by the cable. It is important that all the instruments be kept clean and dry, and that the wire used for connecting them and for the lead have a high insulation. The leakage from the instruments and lead should not be more than a few divisions, ten at most; if much more than this is observed the connections should be overhauled, and the trouble remedied. It can readily be ascertained whether the leakage, if an undue amount is observed, is in the lead or the instruments by disconnecting the lead entirely and testing the instruments alone.

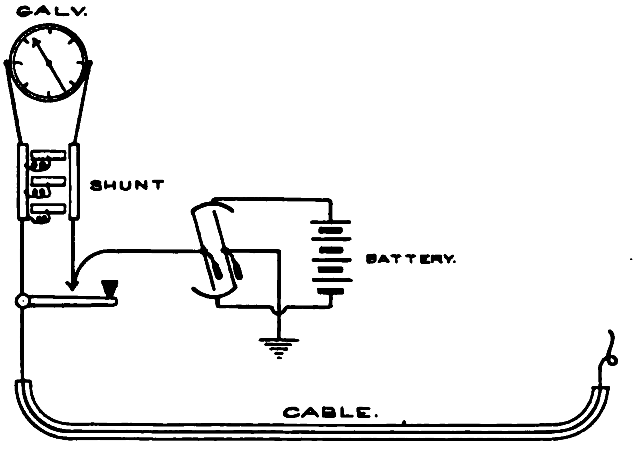

FIG. 30.—CONNECTIONS FOR INSULATION TEST.

Special attention should be paid to keeping the leads in good order; the testing room ends, being connected to the insulated binding posts, need never be touched, but the ends that are joined to the cables or wires to be tested should be trimmed occasionally, the insulation being tapered so as to expose a considerable surface between the wire and the braiding; the attendant who makes the connections should be instructed not to handle the lead near the extreme end but to hold it about six or eight inches back; if the end of the lead is handled much the insulation will become soft and perhaps damp, giving rise to surface leakage. When testing submarine cables, or wires submerged in a tank, both ends should be carefully trimmed and the insulation coated with hot paraffin for a short distance back to prevent surface leakage.

The insulation of the instruments and lead having been tested and found "O K," the cable is connected to the lead and the current turned on by means of the battery key, the zinc pole of the battery being applied first. A few moments after turning on the battery the short-circuit key should be depressed, throwing the galvanometer into circuit. The short-circuit key should always be left closed when the current is first applied to avoid sending a sudden charge through the galvanometer, which would cause the needle to be violently deflected and perhaps partially demagnetized.

It will be observed that the deflection obtained, instead of remaining steady, as with the constant, gradually decreases; the resistance of the dielectric being apparently augmented by the application of the current. This phenomenon is called *electrification*, and no clear and satisfactory explanation of its cause is forthcoming, although it is attributed to a sort of polarization of the insulating material by the action of the current. Electrification is especially marked with homogeneous dielectrics, such as gutta-percha and india rubber; it is greater with the latter, than with the former and with both materials it is greater at a low than at a high temperature.

With cables having a dielectric of fibrous material saturated with paraffin or resinous compounds electrification is very rapid for the first minute or two and subsequently very slow, or almost stationary. A cable of this description if subjected to a temperature sufficiently high to lower the insulation to any considerable extent will not show any electrification at all, the deflection remaining practically constant however long the current is kept on. A steady deflection and gradual electrification are signs of a good cable; absence of electrification, oscillations and kicks of the spot denote the reverse. In testing submarine cables, or rubber covered wires submerged in water, special attention should be paid to these indications. The deflection may be steady and show fair electrification, but if any sudden kicks are observed, even though they be very small ones, they may be taken as an almost sure indication that the wire or cable has an incipient fault which will probably be completely broken down, or at any rate developed sufficiently to proclaim its existence beyond doubt, by the steady application of the zinc pole of a battery of several hundred cells.

Another sign of a good cable is that it should give equal deflections with both poles of the battery. The zinc current is always applied first as it has the effect of accentuating any fault or incipient defect, and as a general rule the readings with the zinc pole are considered a sufficient indication of the condition of the cable; but if any weakness is suspected the cable is thoroughly discharged by being connected to earth for some time after the zinc current is discontinued, and a set of readings are taken with the copper pole of the battery to line. These readings should correspond with the first; if they do not—provided the cable has been completely discharged between the two applications of current—the test is not considered satisfactory and the cable will probably not last in good condition for very long.

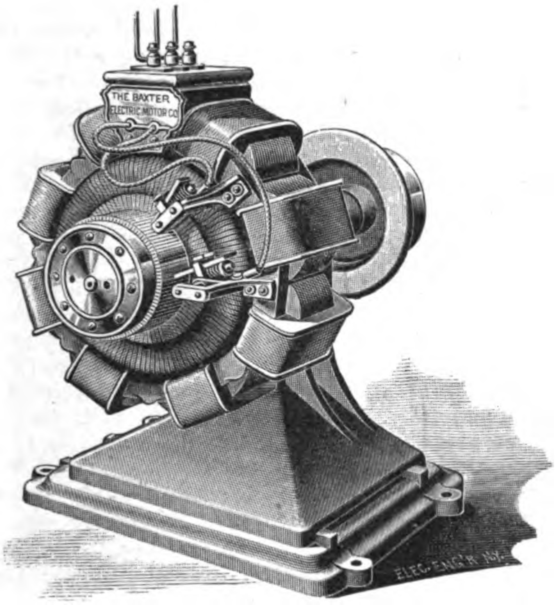
These refinements in cable-testing are scarcely applicable to every-day work, but should always be applied when testing cables at a factory for acceptance or rejection, as the various points enumerated above throw considerable light on the specific quality of the dielectric and its prospective durability. It is not to be imagined that any relaxation of careful methods is advocated in every-day work, but it is not generally necessary in making periodical tests to take reversals or to take more than one minute's reading with the zinc current on each wire, except in the case of new cables or when a fault is suspected.

---

* In Fig. 29, the connections are shown without earth.

THE BAXTER STATIONARY MOTORS.

In our last issue we described the new electric street railway car arrangement designed by Mr. William Baxter, Jr., of Baltimore, in which an 8-pole machine was ingeniously disposed under the car as the driving mechanism.



THE BAXTER
ELECTRIC MOTOR CO.
ELEC. ENG'R. N.Y.

Fig. 1.—The Baxter Constant Potential Motor.

Mr. Baxter has also carried out the multipolar construction in a complete series of stationary motors both of the constant potential and constant current type, and has introduced a novel construction of machine by which greater simplicity and accessibility to all the parts is attained.

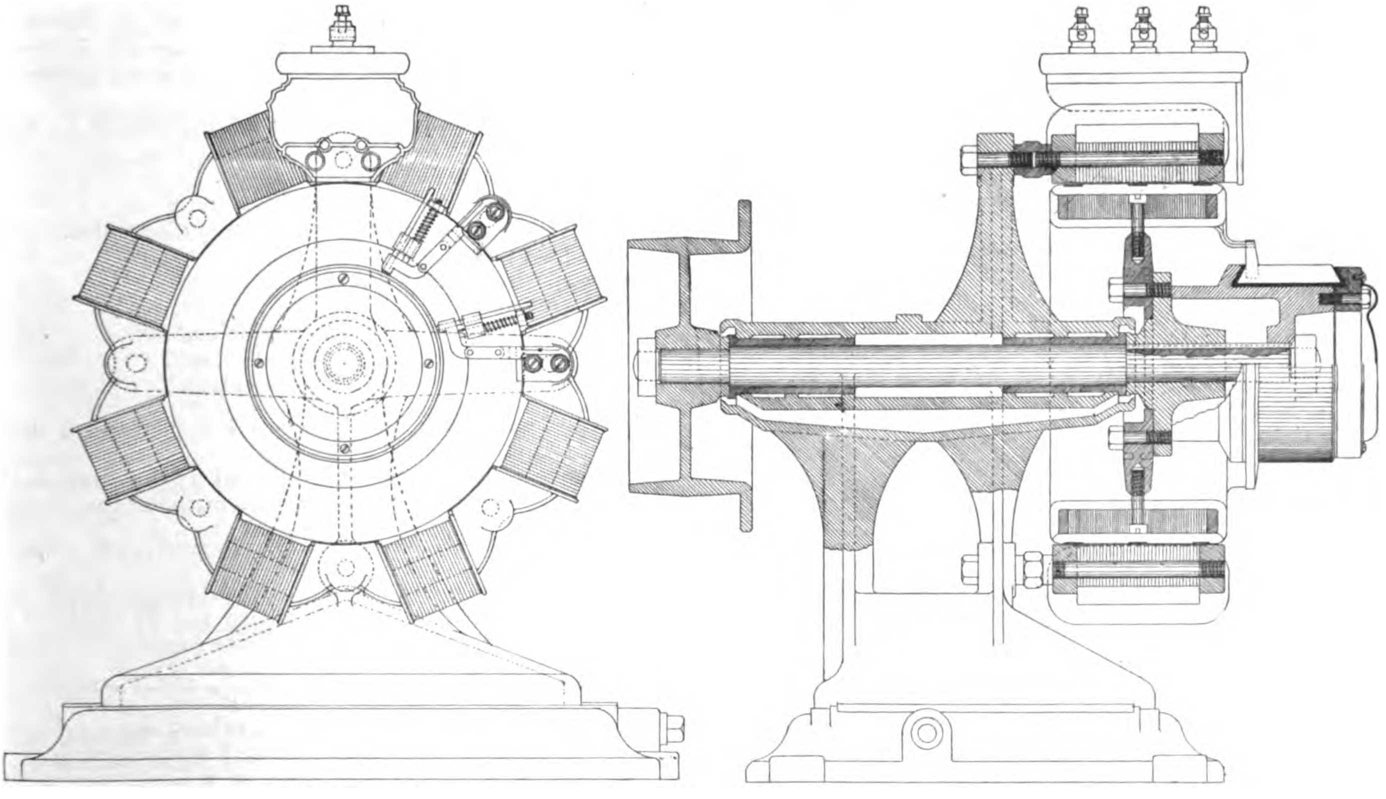


Fig. 2.—Elevation—The Baxter Constant Potential Motor—Fig. 3—Section.

The accompanying engraving, Fig. 1, shows the new constant potential motor in perspective, and Figs. 2 and 3 show an end view and section of the machine. The eight pole pieces of which the fields are composed are of the consequent pole type and all are thoroughly laminated. Mr. Baxter in these machines also employs the toothed armature with a very small air space, as the absence of wire at the periphery allows the armature to be brought very close to the fields. A long shaft is employed bearing at both ends and carrying at one end the pulley and at the other the armature. By taking the pulley off and removing the brush holder, the armature can be entirely slid out from the field and inspected or repaired with ease.

The field magnets are connected to the frame by a bracket connected to the four like poles, so that no tendency to leakage can occur, which indeed is also prevented by the interposition of brass intermediate pieces. The brushes, it will be seen, are placed at an angle of 45 degrees and are fixed in position, the machine being so designed that no shifting of the brushes is ever necessary. The 8-horse-power machine which is designed for 500-volt circuits has an armature 14½ inches in diameter and 6½ inches wide. It is wound in 136 sections of 10 turns each with No. 14 wire. Its resistance is 1.15 ohm. Each field magnet has a cross section of 5¾ square inches and is wound with No. 23 wire, the total resistance of the fields being 1,100 ohms.

The section of the machine, which is designed both as a dynamo and motor, shows clearly the method of supporting the armature and the field magnets. The armature, it may be mentioned, is wound with flat wire which permits of economy in space in wiring. The motor being automatic in its regulation requires no auxiliary regulator, and only three binding posts on top of the machine connect with the starting switch

The machines of this type are built in capacities of from 3½ h. p. to any desired size. The arc machines now being built by the Baxter Electric Motor Co., of Baltimore, are similar in design to the machine just described, but have a third brush which is moved by a governor placed inside the commutator and the motion of which is transmitted by a lever so as to move the third brush to keep the speed constant. These latter machines are also built over a large range of capacities. This type of machine allows of very compact construction, and, being multipolar, slow speed is obtained without sacrifice of efficiency.

ON THE ARRANGEMENT OF VATS IN ELECTRO-DEPOSITION.—I.

BY

C. O. Mailloux.

SOME thirteen years ago, M. Gramme, in France, and Mr. N. S. Keith, in this country, both advanced the theory, based upon experimental facts, that the power expended in depositing copper electrolytically, can be reduced indefinitely by increasing the number of depositing vats connected in series. The account of M. Gramme's experiments on copper deposition, submitted to the Académie des Sciences in 1877, by M. Hippolyte Fontaine,[1] contains what is perhaps the first mention of this theory in the statement or commentary "that with a fixed expenditure of power, it is possible by means of suitable arrangements to almost indefinitely increase the total deposition." Although referred to and commented upon afterward, this proposition does not seem to have been questioned until the summer of 1883, when the present writer was taken to task by a correspondent in the *Engineering and Mining Journal*, for having endorsed it in his article on "Electrolysis in the Metallurgy of Copper, Lead, Zinc and Other Metals," prepared for, and published by, the U. S. Geological Survey Department.[2] No attention was paid to the objections then raised, revealing as they did, a rather opaque knowledge, not to say a complete ignorance, of the electrical principles involved.

The theory has recently been assailed, however, by seemingly competent authorities in England, and has given rise to a controversy between this journal and one of its English contemporaries. The previous acceptance of this theory by the writer, as just indicated, and his experience of several years in the electro-chemistry and electro-metallurgy of several metals, more especially copper and lead, are his apology for presenting a few observations bearing on the points in controversy. If additional excuse were wanted it would be the writer's surprise that, at this late day, such a simple matter should be so obscure, when the magic touch of Ohm's law can make it clear so easily.

There are certain fundamental principles in electrolysis that are established definitely as the result of scientific demonstration, and are consequently admitted by all. It is, for instance, regarded as a fact that the electro-chemical relation or "equivalence" of a given current is definite, and constant for each element, the same as its atomic weight. This equivalence, in the case of copper, is, according to recent accurate determinations, said to be 0.32709 milligram per coulomb. Remembering that 3,600 coulombs are equivalent to an ampere-hour, and taking the kilogram as = 2.2046 lbs., we may express the equivalence, *i. e.*, the amount deposited, per ampere-hour, in any of the following ways:

1 ampere hour = 1177.5 milligrams.
" " = 1.1775 gram.
" " = .0011775 kilogr.
" " = .00259592 lb.

Instead of stating the equivalence as so much per ampere-hour, we may state it reciprocally as so many coulombs or so many ampere-hours per kilogr., or per lb. A simple calculation gives:

1 kilogr. = 849.2 ampere-hours.
1 lb. = 385.2 " "

This equivalence might also be stated by saying that the copper deposited from a suitable solution by the passage of an electric current varies in *rate* with the rate of current passing and in *amount* with the quantity of current sent through; the ratio being always constant and of the numerical value given above.

If a large current is used the deposit will be at a more rapid rate, and the time required for a given weight will be correspondingly reduced. Thus, a current of one ampere will require 385.2 hours to deposit one pound of copper, while a current of 385.2 amperes would do it in one hour.

The amount of deposit is, then, a measure of the *quantity of current* which has been allowed to act on the depositing surfaces, in an electro-depositing cell. It is by no means, however, a measure of the *amount of energy* involved. Each unit of current has, in passing through the depositing cell, recorded or registered itself by depositing a unit mass of the particular substance, copper for instance, just as each unit quantity of water or gas registers itself in passing through a meter. In either case the "record" gives no information whatever as to the amount of energy present. To estimate this we must consider an additional factor, the electrical pressure. The electrical energy consumed by the current sent through a depositing cell, is, therefore, measured just as in ordinary metallic circuits, by the product of the rate of current flow (C) and the pressure (E). It is easily seen now that in electro-deposition generally, the amount of energy will, *for a given current*, vary with the potential difference required to impel that current. If, then, it can be shown that this loss of potential is not fixed for that given current, but is susceptible of variation, it follows at once that the power consumed per unit weight deposited is not fixed either, but is capable of being controlled by changing the conditions. To this end let us briefly analyze these conditions.

The loss of potential in any electrolytic action proceeds from two causes: First, the portion needed to overcome dead or "ohmic" resistances in the liquid and solid bodies composing the circuits; second, the portion absorbed in overcoming the "live" or polarization resistance resulting from the chemical reactions produced at either, or both, electrodes by the current passing through the cell. The first portion of the loss will vary directly as the current density. The second also varies with the current density but to such a slight extent that we may, for the present, regard it as constant.

To make these and other relations of the principles involved more readily apparent, we may express the conditions in symbolic language by letting

r = resistance of electrode plates.
R = resistance of electrolyte between electrodes.
ε = polarization factor.
ρ = spurious resistance.
C = current.
E = potential difference at terminals of cell.
W = energy consumed in deposition cell.

The value of r, the resistance of the plates, is determined by the well known formula $\frac{l'\,s'}{a'}$ where l' is the length, and a' the sectional area, of the path followed by the current, s' being the specific resistance. In like manner the liquid resistance R can be expressed as $\frac{l\,s}{a}$. In reality, however, the current follows many different paths through both the electrodes and the electrolyte. Hence the symbols l' l, and a' a, must be understood to indicate average or mean values; or, more properly, the terms $\frac{l'}{a'}$ and $\frac{l}{a}$ must be taken to signify *effective* or resultant values, which latter will usually be *less* than those obtained by applying the above formulæ in the ordinary way, as a little reasoning will easily show. The *effective* resistances r and R, will, in consequence, be both slightly less than their calculated values unless the formula is modified by having recourse to the calculus.

Since the total dead resistance of the cell is $r + R$ the loss of potential occasioned in this resistance by a given current C will be:

---

[1] Comptes Rendus, August, 1877.

[2] "Mineral Resources of the United States." Edited by Albert Williams, Jr., U. S. Geological Survey Dept., 1883. pp. 627-658.

$$= C\,(r + R) \qquad (1)$$

The current will induce chemical reactions at both electrodes, causing the metal surface of the anode to be dissolved, while a deposit is produced at the cathode. The principles of thermo-chemistry show that the chemical actions taking place at the anode require energy to be added to, while the actions occurring at the cathode will (normally) require energy to be removed from, the substances taking part in the respective chemical combinations. The electrical current, being the agency by which the energy is transferred, must supply the "deficit" at the anode and take up the "surplus" at the cathode. The difference between the two is the net gain realized, or, as the case may be, the loss sustained, by the current in doing the electrolytic work proper. In electro-deposition the difference is generally a loss. The phenomenon of "polarization" is both the evidence and the measure of this loss. The energy required to make up the loss is abstracted from the electrical energy of the current by causing a reduction in the potential, the effect being the same as if the polarization caused a back pressure or counter E. M. F. which we will designate by ε. The polarization might also be expressed as a "live" or spurious resistance ρ, whose value is taken such that $C\rho = \varepsilon$.

The total potential difference E required at the terminals of the cell to force the current C through it can now be written, as the sum of the two losses noted above:

$$E = C\,(r + R) + \varepsilon \qquad (2)$$

or else

$$= C\,(r + R + \rho)$$

The energy consumed in the cell will be

$$W = C^2\,(r + R) + C\varepsilon \qquad (3)$$

This equation applies to all cases of electrolysis in general. In the particular case of copper the factor ε happens to be exceedingly small.

As our object is to make a general and comprehensive demonstration, let us treat this factor as if it were of importance, as it often is with other metals, like nickel for instance. In part II we will see if it is possible to vary the consumption of energy while keeping the deposit constant.

THE DISSOCIATION OF CARBON DIOXIDE GAS BY THE ELECTRIC SPARK.[1]

An interesting paper is communicated by Prof. von Hofmann, to the current number of the *Berichte*, upon the dissociation of carbon dioxide gas into carbon monoxide and oxygen by means of the electric spark. Dalton and Henry long ago showed that carbon dioxide, although formed by exploding a mixture of two volumes of carbon monoxide with one volume of oxygen by the passage of an electric spark, is again partially decomposed into carbon monoxide and oxygen by the continued passage of the spark. Prof. Hofmann has now determined the exact conditions under which the explosive recombination occurs. The most suitable distance apart of the platinum terminals appears to be between two-and-a-half and three millimetres, and Prof. Hofmann advises the use of adjustable terminals rather than the ordinary platinum wires fused into the side of the eudiometer. A Leyden jar in the circuit renders the occurrence of periodical explosions more certain. The spark should also pass at about a quarter the height of the gas column instead of, as usual, near the top. The current itself, moreover, should not be too strong; that from two Bunsen cells and only a moderate sized Ruhmkorff coil yields the best results. It is also preferable to use a volume of carbon dioxide, previously dried over sulphuric acid, not exceeding ten cubic centimetres at a pressure of 650-700 mm. Under these conditions, the first explosion usually occurs in about 15-20 minutes. The second and succeeding explosions occur after shorter intervals than the first. This experiment is certainly one of the most interesting in all the range of dissociation phenomena.

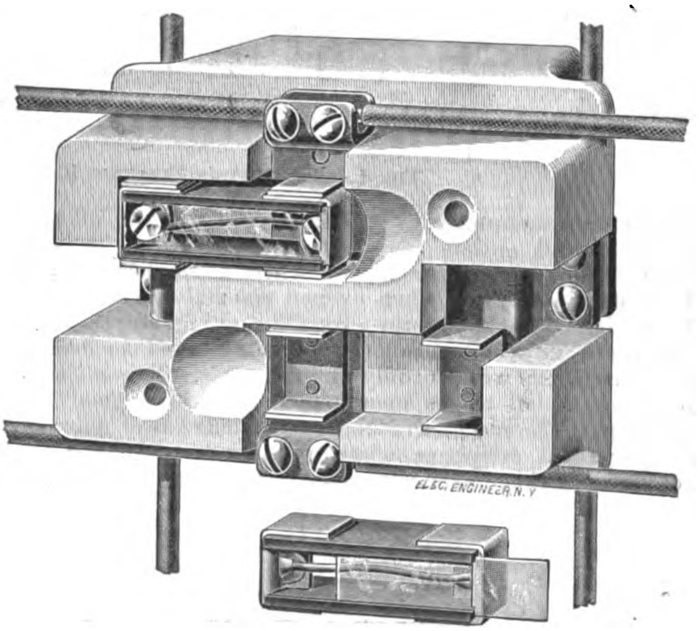
THE BURNET BRANCH BLOCK AND CUT-OUT.

Much difficulty has in the past been experienced in the replacing of fusible cut-outs in branch blocks when an overload has caused the blowing of the fuse. In order to simplify this operation Mr. H. W. Burnet, of East Orange, N. J., whose double pole switch was recently described in these columns, has designed the block illustrated in the accompanying engraving.

In this block the fusible wires are encased in separate boxes. One of these is shown in position in the block and the other below it. As will be seen, it consists of two side strips of vulcanized fibre which are held firmly together by two end pieces of brass. The top and bottom of the case are covered with mica, which fits in grooves, thus permitting the opening of the box at any time. To the brass ends of the case the fuse wire is soldered, or, if desired, it can be connected by screws, both forms being shown in the engraving.

The little case so constructed is slipped into a pair of clamp contacts provided for it. As a result, if the fuse should blow, the little case can at once be removed and replaced by a fresh one; or the fuse wire can, if desired, be renewed in the old one.



Burnet's Branch Block and Cut-Out.

The enclosing of the fusible wire in the insulating case prevents all danger of fire from flying particles of molten metal and at the same time allows of the inspection of the fuse wire at all times, without the removal of any covering parts. It will also be noted that the branch wires are thoroughly protected from contact with one another.

Among the other advantages of this block are that the wires may be run directly and the block inserted afterwards, or vice versa, as by the construction it is evident that neither the branch nor the main wires need be cut. The construction also admits of the easy connection of wires and allows of their being drawn taut at any time afterwards. Where the fuse wire is secured by screws any desired size may be inserted. The block illustrated is made in various sizes for branch and main cut-outs.

THE NATIONAL SYSTEM AT JAMAICA, L. I.

A plant of the alternating system of the National Electric Manufacturing Co., of Eau Claire, Wis., has been put in at Jamaica, L. I., by the Jamaica Gaslight Co., a corporation of 40 years standing. The plant comprises a 1,000 light dynamo, with a 100 h. p. engine and a boiler of 125 h. p. Three hundred lights is the figure at which the plant starts off, and the Brooklyn *Times* reports the installation and the results to be very satisfactory.

MANSFIELD'S UNDERGROUND ELECTRIC RAILWAY SYSTEM.

Although the desirability of replacing the overhead conductors of the electric railways in our large cities is well recognized, the construction of a proper underground system to take the place of the former is by no means an easy problem. One of the principal obstacles to be overcome in an underground system is the short circuiting of the conductors by moisture. The extent to which this occurs depends upon the amount of moisture in the street and the number of cars out. Whenever salt is used in the street, even in small quantities, the trouble is greatly aggravated. When slush covers the street the difficulty is almost insurmountable. The slush will not run off and chokes up all outlets for the escape of water, as was recently demonstrated in Boston where a number of manholes or catch basins when opened resembled a barrel of flour filled to the brim; the slow filtering of water through the increasing accumulation of snow had packed the basins solid and many were entirely unserviceable. This is liable to happen to all basins upon which conduits depend for drainage. The recent weather when thousands of miles of telegraph and telephone wires were rendered useless on account of leakage even with very low potential shows how imperative it is to have all exposed parts of an electric railway system reduced to a minimum.

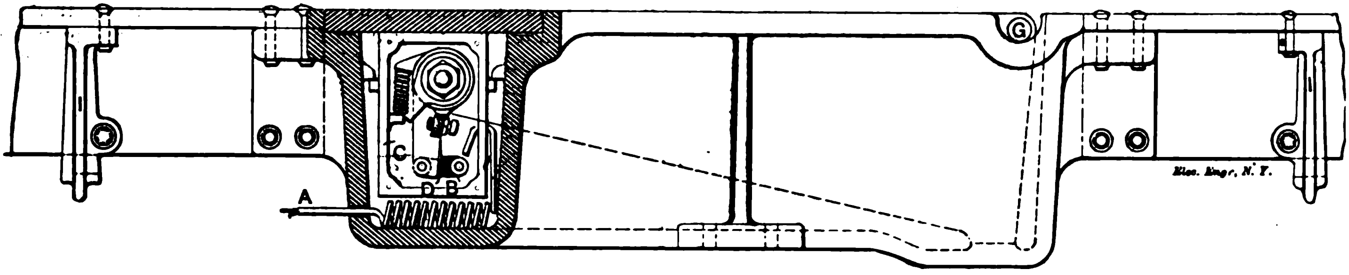


Fig. 1.—Mansfield's Electric Railway Underground Conductor System.

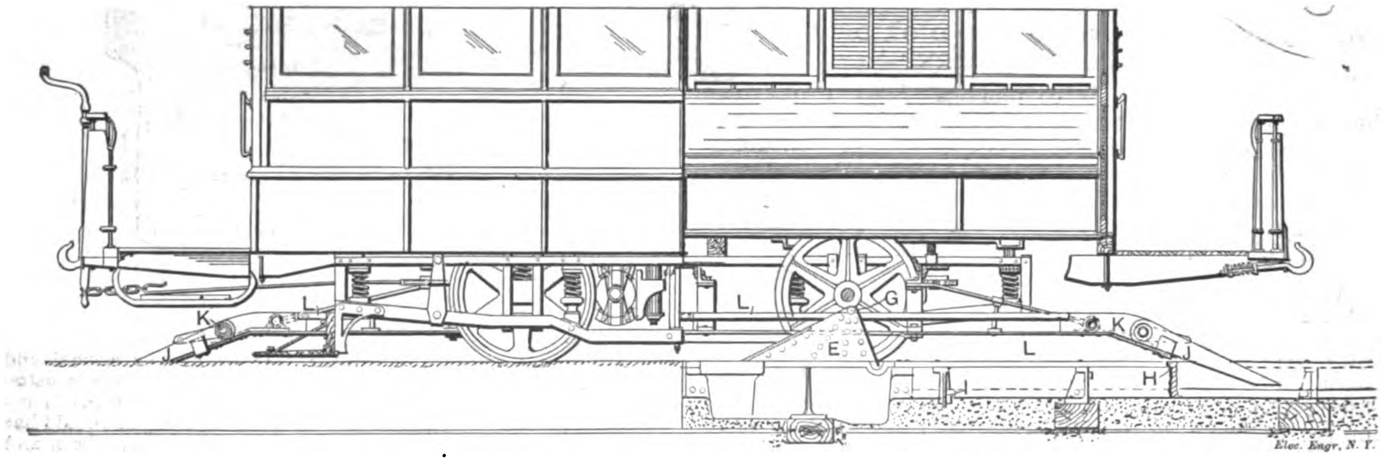

Fig. 2.—Mansfield's Electric Railway Underground Conductor System.

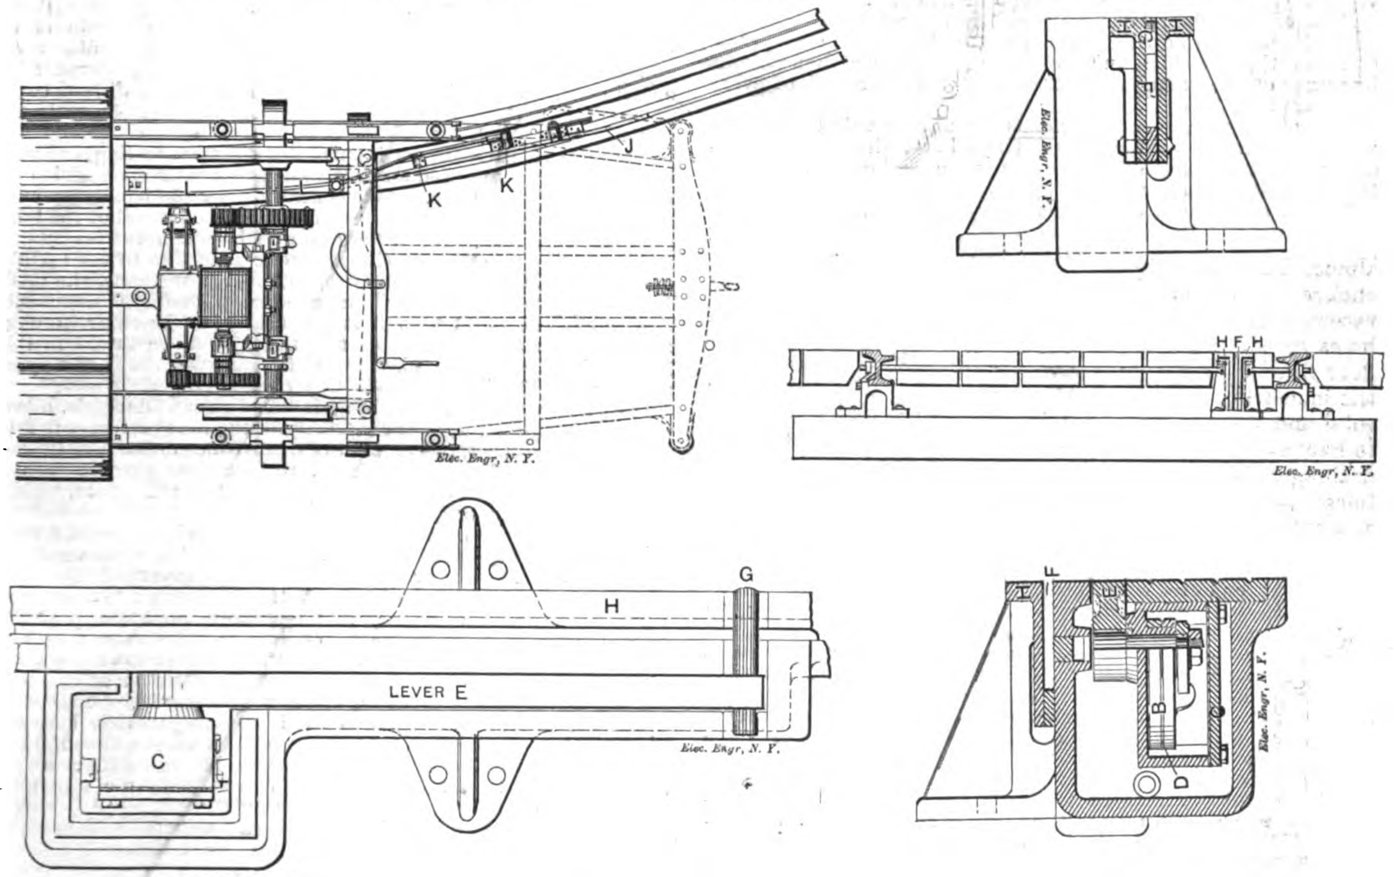
In seeking to avoid this evident drawback Mr. F. Mansfield, of this city, has designed and recently patented a system which may be said to avoid the use both of an expensive conduit and of overhead wires. The inventor has set himself the problem to secure an electric railway system that cannot be interfered with by water and shall at the same time be mechanically perfect. This has been carried out by maintaining a minimum amount of exposure of a branch conductor dead until it is elevated a considerable distance above the surface of the ground and put in electrical connection with the motor on the car. Consequently in the Mansfield system all wires are so housed that, with no cars on the line, the entire outside circuit is completely insulated. With each car run out there becomes exposed a small knob half the size of a man's thumb, and even this is not in electrical connection with the mains until raised eight inches above the surface of the ground. By this novel construction a minimum leakage is obtained. As the car passes along over the track it lifts and makes electrical connection with these knobs successively, making one before breaking with the preceding, electrical connection with the mains being open at all time except when a car is passing over the particular knob; nothing is in sight along the track but occasional boxes and a guide slot, all flush with the surface of the street.

The accompanying engravings will give a clear idea of the conduit and the method of its construction. A continuous well-insulated main conductor runs the length of the track either overhead or underground. Primary insulated branch conductors A run from the main to one pole of a switch B in a water tight box, C. These switch boxes are placed at regular intervals, about twelve feet apart along the track, having their tops flush with the surface of the street. From the other pole D of this switch box a secondary branch conductor runs along a lever E placed in position parallel with the track. The lever referred to is hinged to the switch box C and at the other end has an insulated knob G that is adapted to be raised above the surface of the street, and which projects across the top of the guide slot F. The secondary conductor connects D to this knob G and is thoroughly insulated up to that point.

The guide slot as shown is formed of two angle irons H held apart by yokes I so as to leave a slot five-eighths of an inch wide and six inches deep. This is called the guide slot. It extends the entire length of the track and its office is to guide a pick up arrangement K carried by the car under the successive lever knobs. The pick-up arrangement carried by the car consists of a slightly curved and inclined tongue J armed at the end with a wear plate. The tongue is flexible so that it can be bent laterally and is hinged to its support. It projects downwards into the guide slot.

As will be seen there is a tongue at either end of the car. The hind tongue allows of reseating the lever. Joining the plow hinges there extends a laterally flexible contact bar L insulated from the truck. It serves to support the lever along which the exposed knob rubs, making electrical connection with it and thence to the motor by means of a wire.

The operation of the system will now be readily understood. As the car moves along, the forward pick-up plow runs under the exposed knobs, on the end of the levers that extend across the guide slot in the path of the plow, elevating the same to their full height and thus closes the switch in the water tight switch box and also establishes a sliding contact with the contact bar and thence to the motor. The current returns through the motor and rails to the source of supply.



Figs. 3, 4, 5, 6 and 7.—Mansfield's Electric Railway Underground Conductor System.

The car can run in either direction at any time by merely reversing the controlling switch. By an ingenious arrangement of fusible plugs a grounded knob is cut out of circuit and by means of a forerunner connection is made with the second lever ahead and the car runs off the grounded knob. This operation is performed by the driver.

The lever and switch box being fastened together they can be jointly removed and replaced by merely taking off a cover if by chance they should get out of order.

"L'ELECTRICIEN" AND "LA REVUE INTERNATIONALE."

Beginning with the new year the above journals will be combined under the title of *L'Electricien, Revue Internationale de l'Electricité et de ses Applications.*

It is with sincere regret that we learn that the editor of our admirably conducted contemporary, *L'Electricien*, M. E. Hospitalier will not be connected with the new enterprise, on account of other more pressing duties. M. Hospitalier has long been known as one of the brightest and best of French writers on electricity, being one of the few who possess the power of easy and accurate expression. We wish our new contemporary the same success under the new regime as *L'Electricien* has enjoyed in the past.

A CASTING FOR THE BIG FERRANTI DYNAMOS.

A correspondent to *Engineering* describes the process employed in making some of the large castings for the 10,000 h. p. dynamos for the London Electric Supply Corporation: November 7, there was cast at the works of the Carron Company, the contractors for the cast iron work for the 10,000 h. p. dynamos shortly to be erected at Deptford, the first of the eight 23-ton castings which form the feet of the magnet frames, and which will eventually have to carry the whole weight of these frames, amounting to many hundred tons. As these measure some 12 ft. by 10 ft. by 6 ft. 6 in., and have each cast into their body the projecting ends of eleven magnets or blocks of soft iron 3 ft. 3 in. by 1 ft. 6 in. by 5 in. and weighing in all about 4½ tons, some idea may be formed of the nature of the casting. The greatest difficulty the contractors have had to overcome in the manufacture of these magnet frames has been the securing into the casting in a thoroughly fast and trustworthy manner of these large blocks of soft iron; this being absolutely necessary owing to the nature of the forces brought to bear on the magnets when the dynamos are at work. Possibly, owing to the very unusual nature of the casting, the same difficulty may not previously have presented itself to the founders in any case. All the ordinary methods of casting failed to secure the desired end, and very special and novel treatment indeed has had to be resorted to before a satisfactory solution of the difficulty has been found. What in ordinary circumstances would form the main core of the mould has built into its interior a light steel tank of the necessary form and dimensions to suit the magnets, and into this vessel the magnets project for about 2 ft. of their length. You have thus at once a core fulfilling all the ordinary functions of such, and at the same time in itself a water-tight vessel surrounding the magnets. After the metal has been run into the mould and allowed to set, cold water is immediately passed through the tank or vessel and caused to circulate round the magnets, but not in contact with the cast iron, for a period of from two to four days. After this time, and during which the cast iron has been kept warm as long as possible, it is found that the magnets are firmly bound into the casting and practically form a part of it. As the contractors have already cast over twenty 12½-ton castings on the same principle, only applied somewhat differently, the process may be said to have been subjected to a thorough test. The process was introduced specially for the occasion and has since been patented.

Mr. A. Irvine, representing the National Electric Manufacturing Co., Eau Claire, Wis., has sold a 1,000 light alternator to Desoto, Mo.; 500 lights to Bushnell, Ill.; 500 lights to the Home Electric Light Co., Cape Girardeau, Mo., and 500 lights to Centralia, Ill.

THE PHENOMENA OF EARTH CURRENTS.[1]

BY WILLIAM FINN.

If you place a sensitive galvanometer in any well insulated telegraph line from which the regular battery has been withdrawn and ground the opposite ends of the wire the chances are that you will find a current in the wire of sufficient strength to deflect the galvanometer needle. After repeating this experiment a number of times, you will probably conclude that the current is not a constant one, but on the contrary varies more or less in strength and sometimes in polarity also. The movements of the needle may be very sluggish at one time and play over but a few degrees of the scale, while at other times the needle may oscillate in the liveliest manner over a considerable portion of the scale on both sides of zero, showing great variations in the magnitude as well as in the direction of the current.

When you open the wire at either end these manifestations instantly cease and do not reappear until the ground connection has been again established.

It will be evident from this that the effects observed do not proceed from induction, or stray currents from neighboring wires, either of which would tend to act more strongly upon the galvanometer on opening the wire at the distant end.

The effects observed are in reality caused by currents of natural electricity flowing from place to place over the surface of the earth, and which find their way into the telegraph circuits by means of the ground connections which form a part of every telegraph line.

These currents are not sufficiently strong as a rule to interfere with the ordinary working of telegraph lines, though I shall endeavor to show later on that there are times and conditions when they cannot but impair the efficiency of working.

The investigation at various periods and by different observers into the cause of these currents has led to some very interesting and important scientific discoveries and deductions.

The apparently confused mass of data furnished by different observers on this subject, made it exceedingly difficult at first to derive any tangible results therefrom, but a careful analysis of the records has since shown that the earth current is not so erratic as might at first sight appear, but is on the contrary comparatively regular in its variations and subject to a law. Here, for instance, is a plotted record of some observations taken at Valentia upon about 300 miles of the Atlantic Cable which was lost in 1857. These early observations which extend over a period of 36 hours, were taken at short intervals apart, and the result as reproduced in the form of curves, affords a very fair idea of their regularity and periodicity.

But the most important point was the close connection observed between the variations of the earth current on the one hand, and the periods of high and low water marks on the other, as may be seen from the plotted current and tidal curves represented on the screen. In this was found a coincidence which at once suggested a clue to the possible cause of these mysterious earth currents, and the question at once arose, Were the rising and falling waters of the ocean directly responsible for their appearance, or were the same causes which created the tides to be held accountable for the earth current phenomonen also?

The tides as you know are mainly due to the influence of the moon's attraction for the waters of the globe; the relative position of the earth and moon determining the times and places of high and low water. And very much in the same way it was contended that the moon affects the distribution of the earth's electricity also, and creates electric tides or currents of electricity which flow over the earth's surface. This appeared quite plausible and agrees exactly with our knowledge of what would occur experimentally with two electrified spheres arranged to imitate the relative motions of the earth and moon.

This theory was apparently confirmed by the records obtained from subsequent observations. On the other hand this theory was so incompatible with the results of many other observations, that recourse was taken to the consideration of the next question, viz., Did the undulations of the waters of the globe, by friction or otherwise, produce those inequalities of potential at various points of the earth's surface which gave rise to the generation of electric currents?

The first consideration relative to friction was not favorably or seriously entertained, but it was thought highly probable that the moving mass of waters across the earth's magnetic lines of force might account for the phenomenon.

I have here an apparatus which will prove to you that the induction phenomena observed with a magnet holds equally good in the case of the terrestrial lines of force. The instrument is called a terrestrial induction coil, and consists essentially of a wooden ring 6 inches in diameter, upon the circumference of which has been wound an insulated wire measuring 320 ohms. This coil is made to rotate around a horizontal axis, and is placed in such a position with respect to the earth's magnetic lines of induction that the greatest number of them will pass through the space bounded by the encircling wire. This position is obtained when the plane of the coil is at right angles to the direction assumed by the dipping needle.

If I now connect the ends of the coil with a sensitive galvanometer and make the coil revolve, the convolutions of the wire will move across or "cut" the earth's lines of force, which in this instance may be likened to a shower of rain falling at an angle of 72°. The result is that induced currents are generated in the coil, which as you notice produce marked deflections on the galvanometer.

The manner in which the great tidal waves of the ocean in their movements to and fro affect this magnetic field, and how induced currents are thereby generated and circulated over the earth's surface, will now be more clearly understood. It is not at all improbable that local currents may even be developed by rivers and running streams flowing over these imaginary lines of force, and some experiments made by the writer on wires running parallel with, and at right angles to the Niagara river appear to demonstrate the correctness of this view. (Experiment shown.)

Of the two theories under discussion the latter appears to be most in accordance with the result of observations taken by the writer both here and in England. There is considerable difference in the limits of the variations and strength of the earth current in this section of the country as compared with records of the same features in England. For instance, the average strength of the British earth current is said to be about one-tenth of a milliampere while here it is certainly not less than double that amount, and very often exceeds one and two milliamperes, and occasionally rises as high as four milliamperes, with a difference of potential at opposite ends of the wire in some cases of nearly 10 volts.

My experience with earth current deflections in England was that it usually required a sensitive astatic needle upon which to take the readings. Here, on the contrary, they can be read on any wire at almost any time by inserting the 200 ohm coil of the tangent galvanometer. This difference may be accounted for by the fact that the intensity of the magnetic field due to the earth's magnetism is not alike at the two places. For instance, the total force or intensity of terrestrial magnetism in Buffalo is about 0.6 dyne, whereas in London it is but 0.4 dyne. In other words a magnetic pole of unit strength in Buffalo, would be urged in the line of dip with a mechanical force of about two-tenths of a dyne unit greater than it would be in London.

Now, since the strength of an induced current depends, other things being equal, upon the intensity of the field of force, it follows that for the same amount of disturbance created in the respective fields of the two places, the stronger current would naturally be developed in the more intense field at Buffalo, which we find to be actually the case.

But even this hypothesis failed to satisfactorily account for all the vagaries exhibited by the earth current, and as a consequence other theories, more or less plausible, were invented, the least unsatisfactory of which is perhaps the following: It is a well known fact that a difference in temperature maintained at the opposite ends of a heterogeneous conductor will cause a steady current of electricity to flow through it. Take for example a bar of copper and one of iron, and solder them together at one end, leaving their opposite ends free, and connect these free extremities with a galvanometer. If now the point of conjunction between the two bars be heated, a current will circulate through the system, and its strength will be proportional to the difference in temperature between the soldered and free ends of the conductors. (Illustration.)

Now the earth is a huge heterogeneous conductor whose opposite sides are kept at unequal temperature by the heat of the sun, and it is quite within the range of probability that thermo-electric currents are established and maintained in the earth the same as in a thermo-electric pile.

The unsteadiness of the earth current together with its variation in direction do not, however, sufficiently harmonize with this theory to make it generally acceptable, though it is interesting to note that the circulation of thermo-electric currents around the earth presents a very plausible basis upon which to account for the magnetic condition of the earth, and in that way these thermo currents may be the indirect means of producing the effects observed.

But, from whatever source these currents of natural electricity flow, they are always to be found in the ground and ready to be tapped, and the question arises: Can they in any way be harnessed and utilized in the service of man as is now the case with the flow of natural gas? The currents are certainly far too weak and unreliable to be of any practical advantage in telegraphy with the style of apparatus at present employed, but, as I stated at the outset, I believe they are sufficiently powerful at times to interfere with the regular working of that service. This opinion is based upon the result of numerous tests made of the value of working currents on certain telegraph lines passing through Buffalo. For instance, the actual value of some of the signaling currents taken on certain polar duplex circuits as well as on the polar sides of quadruplex systems, varies from eleven to thirteen milliamperes, which is not enough current even under favorable circumstances to satisfactorily operate these systems, and for which, as a rule, a great deal more current is allowed. But the appearance of an opposing earth current in the wire under such conditions would aggravate the case by an amount proportional to its strength, and might not only destroy the uniformity of signals, but render them altogether unintelligible,

---

[1] Abstract of a paper read before the Buffalo Electrical Society, Jan. 5, 1891.

I have taken readings from a distant battery whose reversals of polarity have indicated a difference in strength of from one to four milliamperes, when neither the state of the wire nor condition of the apparatus appeared to warrant any such variation. On these occasions the wires have nearly always given evidence of strong disturbing forces emanating from the ground. Their influence can of course be counteracted by increasing the working strength of the battery, or by substituting wires of smaller resistance, either of which would increase the margin of the battery current beyond the variable limits of the earth current.

There are certain characteristics connected with earth current variations, which make the study of that phenomenon not only exceedingly interesting, considered from a purely scientific standpoint, but which are also regarded as possessing features calculated to render them of considerable commercial importance. It has been shown by certain investigators that when uninfluenced by outside interference these currents ebb and flow over the surface of the globe like the tides of the ocean; and that the variations observed on any given wire afford a sort of index to the variations which may be looked for on other wires.

The curve demonstrations not only show its wave-like character, but also clearly define the course of the path taken by the current, which, in the case under consideration, was from a point N. E. to S. W. and happens to represent the prevailing direction of these currents in England.

One other significant fact noted during this particular series of observations was this: There were readings obtained from several other wires at the same time as the above, which did not harmonize either in strength or direction with those already given.

A study, however, of the plotted curves made by these irregular currents, in conjunction with those mapped out by the more regular ones, plainly shows that the discrepancy in the agreement of the results is the outcome of some local disturbing force, the area over which it manifests itself being clearly discernible, as is also the length of time during which the disturbance lasted.

It will be evident from this, then, that the study of the comparative results upon a number of wires around a given point, may lead to most interesting and instructive features having an important bearing, perhaps, on some of those natural phenomena affecting the condition of the globe or of certain localities upon its surface. For example: The disturbance noted in the London records may have been occasioned by some convulsion more or less violent, or other internal forces at work below the earth's surface, due either to local strain—such as upheaval or contraction—or brought about by chemical changes, a knowledge of which might be of the utmost importance. In certain volcanic regions the discovery and study of these internal forces are materially assisted by means of telephonic and recording apparatus attached to buried wires, which instantly convey the intelligence of any unusual commotion happening beneath.

During the course of several months' observations on various wires radiating from Buffalo, I have had many opportunities of noting exceptional fluctuations in the intensity and polarity of earth currents in this vicinity and though I have been unable in the majority of cases to connect these with anything of a definite character, there have been times when the appearance of earth current disturbances has coincided with the occurrence of unusual solar or meteorological phenomena, which fact would appear to establish a close identity between them.

From the result of other observations made here, I am quite convinced that there remains little room for doubt as to the truth of the general law affecting the distribution and direction of the normal earth current.

I have selected from a number of such observations those recorded on wires extending to Toronto, Chicago, Cleveland, Pittsburgh, New York and Albany, on December 14th, which will more clearly demonstrate this point.

The directive force curves show the definite direction taken by the current. This direction is from Cleveland—which shows the most strongly positive reading—to New York, the most strongly negative point. The line of least intensity is that between Toronto and Pittsburgh, or nearly north and south, which may be roughly considered as a direction at right angles to the easterly and westerly course of maximum current.

The telegraph wires of this country are too much occupied, as a rule, to admit of long and systematic records being made upon them, and hence it is somewhat difficult to ascertain with any degree of certainty the prevailing direction of earth currents in the United States, but from the evidence collected here the maximum intensity, in this section at least, appears to extend from a point, N. W. to S. E. The daily records taken on wires between New York and Chicago, show an almost invariable flow of the current from west to east, and it is on such wires as a rule that the maximum effects are obtained.

It occasionally happens that a wire grounded at some terminal office will exhibit totally opposite results as compared with those derived from intermediate points on the same wire. Thus, for example, on a wire grounded at Cleveland on Oct. 1, the earth current deflection was of an electro-positive character; that is to say, one whose polarity indicated that the direction traversed by the current was from Cleveland to Buffalo; but upon having the wire cut and grounded at Erie and Dunkirk, respectively, these two sections of the wire presented an electro-negative appearance of about the same strength as the Cleveland current, and this anomaly in the wire existed for nearly five hours, after which the direction of the current coincided in all three cases.

It thus appears that for some reason or other during the period named, Buffalo was at a lower electric potential relatively to Cleveland, but at a higher potential with respect to the intermediate points, though all these points may be considered as being in the same geographical straight line, and this singular result has appeared on subsequent occasions over the same route, as also on lines extending in other directions.

It is, however, during the periods of maximum sun spots that the more violent fluctuations in the earth currents are felt. The effects observed on the wires at such times are of an entirely different character from those we have been discussing, and are usually classified in the category of magnetic or electric storm current effects. These electrical hurricanes come and go without any warning, and while they last are extremely irregular in direction, and of such enormous magnitude as to almost invariably upset the working apparatus. They also exert a direct influence upon delicately suspended magnetic needles without the aid of any conducting wire. The direction in which they flow is usually a straight line from one ground connection to the other, and not by the actual course taken by the wires, and they sometimes attain a current strength of 30 or 40 milliamperes which is more than is necessary to operate our duplex circuits, and almost powerful enough to maintain quadruplex working.

It is customary in the British telegraph service for the wire chiefs to note particularly the period and extent of these abnormal earth currents at all points where observations can be made without interfering with the regular service; and the data thus obtained is forwarded to London, where it is analyzed, plotted out when necessary, and the result made public before some of the scientific societies.

There are many difficulties in the way of securing records of this description in America owing principally to the "closed circuit" system in vogue here; but it would be possible on such occasions to take note at least of the circuits that are not affected by the disturbing forces, for the direction of such circuits would mark the course of the equipotential lines, which are always at right angles to the path taken by the disturbing elements. Mr. Preece, the well known English government electrician, who has made the subject of earth currents a favorite study for years past, has always entertained the idea that they are directly due to the action of the sun, which by induction brings about a variation in the distribution of the lines of potential on the earth's surface. It appears quite certain that there is a close relationship between the condition of the sun spot period on the one hand, and these great temporary electric storms on the other and all information obtained as the result of accurate and systematic observations on telegraph wires at times of unusual solar excitement cannot but help to bring about important additions to our knowledge of the physical condition of the earth.

RUMORS OF TELEPHONE WAR.

With regard to the extension of the long distance telephone system, and the visit of Mr. A. S. Hibbard to Cleveland, Mr. J. P. McKinstry, of that city, is quoted by the local *Plain Dealer* of December 21, as follows: "It is possible," said Mr. McKinstry, "that the Western Union Telegraph Company may enter into a competition with the Bell Telephone Company in the enterprise now under process of construction. There is quite a story, by the way, relative to an old fight between the Western Union and the Bell telephone people. During the year 1879–80 a contest developed between these two companies. It seems that at Ft. Wayne the telegraph company put telephones in different parts of the city. They furnished a free carrier service to certain parts of the city and gave the public a very excellent service. Everything moved along all right until the Bell company became strong competitors. The result was that the fight between the companies waxed warmer and warmer until a final compromise was effected. By the terms of this compromise the telegraph company sold out their telephone property to their rivals. There was some serious hitch in the transaction and as a final result suit was brought. The suit is pending, I think, at the present time, and the construction of the new telephone line may bring about a renewal of the old difficulties."

Mr. J. M. Denniston, of the Westinghouse Co., has just closed a contract with the Pabst Brewery Co. of Milwaukee, for a 1500 light direct current plant of the U. S. system.

THE DETERMINATION OF THE WORK DONE UPON THE CORES OF IRON IN ELECTRICAL APPARATUS SUBJECT TO ALTERNATING CURRENTS.[1]

BY T. H. BLAKESLEY.

When the case is one of a transformer, the problem may be solved by the employment of three dynamometers in the way I have already pointed out; but in that of an electro-magnet, where we have only one coil to deal with, the problem still admits of solution if we further employ a condenser of determined capacity, and possess a knowledge of the period by means of some speed indicator. The plan is as follows:—

Arrangement.—Having the machine and magnet in series, insert the three dynamometers in series immediately at one terminal of the electro-magnet, placing one pole of the condenser to the other terminal, and the second pole to that point of the middle dynamometer where its two coils join.

Observations.—Obtain good simultaneous readings of the three dynamometers, and, if necessary, of the speed indicator.

Elements of Calculation.—Let a_1, a_2, a_3, be the angles read upon the instrument (1) in the generating section, (2) in the electro-magnet section, (3) which has its coils divided.

Let the reducing formula for the three instruments be respectively,

$$\begin{aligned}(\text{Current})^2 &= k_1\,\theta,\\ \text{“} \quad &= k_2\,\theta,\\ \text{“} \quad &= k_3\,\theta.\end{aligned}$$

Let C be the capacity of the condenser.
R " resistance of the electro-magnet.
T " semi-period.

Then the entire power at work beyond the terminals, *i. e.*, the heating of the wire, the heating of the core by induced currents, and the heating of the core due to hysteresis, is expressed by the simple formula—

$$\frac{T}{\pi C}\sqrt{k_1\,k_2\,a_1\,a_2 - k_3^2\,a_3^2}.$$

The expression itself is independent of the resistance, but if we desire to know the power heating the core, we must deduct from the above the power heating the wire, viz.:—

$$k_2\,a_2\,R.$$

The difference between these two quantities also happens to be proportional to the tangent of the magnetic lag, another proof of the universal concurrency of lag and loss of power.

THE RETURN ELECTRIC RAILWAYS MAKE FOR THEIR FRANCHISES.[2]

BY W. B. FERGUSON.

As there has been considerable discussion through the newspapers relative to cities and towns throughout the commonwealth giving franchises to street railway companies without being compensated in any way, I think it is time for the representatives of the street railway companies to be heard in the matter and state their side of the question. The articles which have come to my notice set forth, among other things: That the franchises are procured without remuneration to the public; that the streets are given up to the monopoly of the street railways without the towns and cities being reimbursed therefor; and in the case of the electric roads, that the danger to life is great; that the profits of the street railway companies are enormous.

In answer to the first statement, I would say that almost every road that has been opened to the public by the street railway companies, has enabled the public to ride from 50 to 100 per cent. cheaper than they could ride on any other public conveyance. As in the case of the proposed extension of the tracks of the Merrimack Valley Horse Railroad to South Andover. The present fare on the steam road is 10 cents between South Andover and Lawrence; it is the intention of the street railway company to charge but 5 cents, and on through cars to Methuen, the same fare will be charged, 5 cents, as at present between Methuen and North Andover. I note this particular case because it comes under the observation of the people of Lawrence and vicinity.

As to the second statement—that street railway companies occupy the streets of towns and cities without due compensation being given therefor, will say that it is a well known fact that it is a law of the State, that the street railway companies shall construct their tracks in a manner satisfactory to the officers of such municipalities and that they shall ever maintain to their satisfaction the space between the rails and 18 inches outside of each rail, thereby relieving the city or town of the expense of keeping that portion of the street in repair, which will usually average from ⅓ to ½ of the entire street; and that they shall so construct their tracks that carriages and vehicles of any kind can pass over them in safety.

One of the benefits that cities and towns receive from the street railway is the increased valuation of real estate along the line of the route.

In the case of electric roads, the towns and cities throughout the State are demanding much more expensive poles than they ever exacted from the electric light, telegraph or telephone companies, and the street railway companies have always been willing to meet the demands of the public in this direction. As to the wires that are necessary, in the construction of an electric road, there is not a single instance where a human being has been killed by the current used in the operation of electric cars; while we all know that the electric light companies are obliged to use a deadly current in order to give a satisfactory service.

Regarding the last statement, as to profits that the street railway companies receive, I would say that the public have a wrong idea, as a rule, as to the profits that are derived from street car traffic. According to the last annual report made by the board of railroad commissioners, the dividends from the street railways throughout Massachusetts averaged less than five per cent, on the money invested.

In conclusion, I would say that if too many restrictions are placed upon the street railway companies, and too many requiremants exacted of them, they will necessarily be unable to give the public the cheap transportation and efficient service that they now furnish.

SOME OF THE TERMS OF THE HATHERLY, MASS., RAILROAD FRANCHISE.

As great interest is taken in electric railway franchises, we append, as an example, some of the more important provisions in the franchise just granted to the Hatherly Street Railway Co., by the selectmen of Whitman, Mass.:—

"The right to lay down the tracks located by this order is upon condition that the said company shall well and truly comply with all the laws of this Commonwealth applicable thereto, also with all the requirements of this order and such further regulations as the Board of Selectmen may from time to time, adopt. Upon condition also that the said company shall give a bond with sufficient sureties to the approval of said Board in the penal sum of ten thousand dollars to comply with the said laws, regulations and requirements and to indemnify the town for all losses, injuries, expenses, suits and actions arising from any carelessness or neglect of themselves or of their employés, or from, or on account of the existence of said tracks. Said tracks shall be laid in conformity with the existing or established grades of said streets and in case the grade of any part of said streets shall be changed by the proper authority, the expense of taking up and relaying said tracks shall be borne by said railway company. In case a change in the grade of said streets or any portion thereof shall be judged necessary by the road commissioners and selectmen for the proper laying of said tracks, the expense of making such change of grade shall be borne by said company including all damages paid abuttors by the town on account of damages, from any such change of grade.

"Where the tracks are laid on one side of the street, there shall not be less than eighteen feet width of space safe and available for carriage travel between said tracks and the opposite curb line of said highway, and whenever any widening of the road bed shall be necessary to comply with this requirement the whole expense of such widenings, including land damages, shall be borne by said company.

"The kind of rail used shall be the Johnson girder rail, weighing not less than forty-five pounds to the yard in conformity with the plan. The remainder of the distance, the same kind or the T rail of the same weight may be used. All rails shall be laid on steel chairs or four by six inch timbers, all such chairs and all timbers under either kind of rails, shall be laid on chestnut or oak ties not exceeding six feet apart between centres, said rails have fish plates at their joints. From West street to the north corner of Vernon street and from Temple street to the west corner of Harvard street, also wherever said tracks cross a street, said tracks shall be paved eighteen inches on the outside and twelve inches on the inside of the rails, the remaining space between the rails to be filled in with crushed stone.

"The paving stones used shall be of the first class subject to the approval of the Road Commissioners. The whole work of laying down said tracks shall be to the satisfaction of the Road Commissioners and approved by the selectmen. All streets shall be left by said company in as good and safe condition as the same may be when the laying of said tracks is commenced to the satisfaction of the Road Commissioners. In case said company shall neglect or refuse to keep its tracks safe and convenient for travelers within the requirements of the statutes necessary and reasonable repairs may be made therein by the town under the direction of the Road Commissioners and Selectmen and the cost thereof, shall be borne by said company.

---

[1] *Nature.*

[2] Open letter of the president of the Merrimack Valley Street Railway Co.

"When there shall occur a fall of snow sufficient to allow the use of conveyances on runners on said streets, no snow plough shall be used on said tracks nor shall said company cause or allow snow to be removed therefrom, nor use or allow to be used any salt or other substance or substances for the purpose of melting snow on said tracks, unless written permission be obtained of the road commissioners.

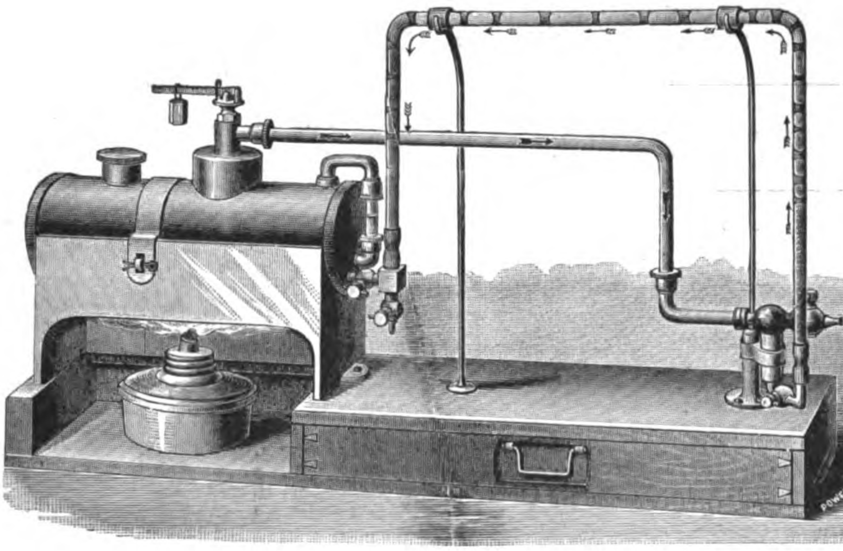
"Said company shall have the right to erect poles and structures for the purpose of operating their road by electricity. Said poles may be sawed square, or round at the option of said company, but whatever kind is used, they shall be straight and well dressed, subject to the approval of the selectmen.

"In all cases where said tracks are laid on one side of a street there shall be not less than three and one-half feet from the curb line of the sidewalk to the rail."

THE STEAM LOOP.

A LONG-STANDING synonym for impossibility has been the inherent inability of water to "run up hill;" but that it can be made to do so without the aid of pumps, traps or any form of mechanism, is demonstrated by the steam loop, a working model of which is illustrated herewith.

The purpose of this loop is to return the water of condensation from a steam system to the boiler from a point either above or below the water level. In the model, illustrated in the accompanying engraving, for which we are indebted to our excellent contemporary *Power*, such a system is represented by the pipe leading from the steam dome of the boiler and discharging through the valve at the right. This, for example, might be the main steam pipe connecting an engine with the boiler. Just before being discharged in the model, the steam passes through a separator which enables the suction or "steam sweep" of the loop to collect the water which has been carried over with the steam or resulted from condensation. The loop commences with the riser at the right. The pipe forming this riser is, at proper height, turned toward the boiler with a slight inclination, and at the boiler again turned to form a drop leg communicating with the interior below the water line.



THE STEAM LOOP.

In order that steam may flow from one point to another a preponderance of pressure is required at the starting point sufficient to overcome the frictional resistance to its movement. It follows then, that at any point on a circuit of moving steam the pressure will be less than that in the boiler by an amount increasing with the distance from the boiler, measured by the flow and the velocity of the movement.

As the riser is placed at the end of the system and the pressure is further reduced by the resistance of the loop itself, it follows that the point of lowest pressure will be in the drop leg. Were the pressure uniform throughout the system the water would stand in this leg at the same level as in the boiler; but, having a lesser pressure above than below, when the stop valve between the boiler and drop leg is opened the greater pressure in the boiler forces the water in the leg upward until the height of the column balances the difference in pressure. The top of this column forms a "dead end" at the point of lowest pressure, and toward it the circulation naturally sets, carrying with it the water of condensation, at first in the form of a spray or a thin film swept along the inner surface of the pipe, and afterwards, when the accumulation of water is sufficient, in the form of small slugs or pistons of water, which completely fill the pipe at intervals, traveling rapidly toward the dead end. This action is very plainly shown in the glass tubes of the model. As each slug is deposited on top of the column in the drop leg it increases the weight of the column above that due to the difference in pressure at the top and bottom, and sufficient water enters the boiler by gravity to maintain the equilibrium.

The arrangement is thus equivalent to a gravity return, the water reaching the boiler continuously and rapidly and at a temperature very nearly that of the boiler itself. Its application to an engine results in removing the cylinder from the dead-end of the system to the middle of an active circulation, overcoming the tendency of water to accumulate at that point and returning to the boiler what would otherwise not only be wasted in the exhaust but would be also a potent cause of trouble and danger to the engine. Its application to radiators, jackets, steam vats and other forms of apparatus where steam is used for heating not only furnishes a simple method of returning the consequent condensation, but results in an active circulation which much increases the efficiency of the heat-using appliance. It is being applied by Westinghouse, Church, Kerr & Co., 17 Cortlandt street, New York.

EXPERIMENT WITH A CONDENSER.

Writing to the *Electrician*, Sir William Thomson says: "On the day after our last meeting of the Physical Society I saw at Deptford, in a test by Mr. Ferranti of a vulcanite tray subjected to 20,000 volts (square root of mean square), a most interesting illustration of one of the subjects discussed in connection with Mr. Swinburne's paper. The tray was rectangular, with rounded corners and edges, and may have been 8 inches or 10 inches long, by 5 inches or 6 inches broad. and 1½ inches deep (I write from memory). The vertical sides ended in a flat lip, about 1 inch broad, projecting horizontally on all sides. It was laid on the bottom of a large metal tray filled with water, and was filled up inside to a depth of about half an inch. During the test we observed a blue line of light all round the water line, both inside and outside, which seemed to be everywhere about a quarter of an inch broad (we did not apply a ruler or compasses to measure it). When the test was completed and the electrification stopped, we took the tray out and looked at it carefully all round. We found, as we expected, that there was no sign of perforation, but we saw a very remarkable appearance all along the lines, inside and outside, which had been the boundaries of the water. They showed, at regular intervals, little vertical marks; the explanation of which was, no doubt, capillary standing waves produced in the water by the electric force, and analagous in hydro-kinetic and capillary quality to the ripples seen inside a finger-glass caused to sound by a wetted finger drawn along its rim. The blue light which we saw was, of course, due to the same cause as the well-known sparkling at the edges of the coatings of a Leyden jar when suddenly charged or discharged. The sparkling described by Mr. Swinburne in his mica condenser was no doubt due to the same cause. When the breadth of a band of sparking round the edge of a metallic coating is considerable in comparison with the linear dimensions of the coating in any condenser subjected to rapidly alternating high potential, there must be considerable heating due to it; and the mere fact of heating would not prove that any sensible proportion of the heating is due to viscosity of electrostatic inductive capacity.

"An internal sparkling or quasi-sparkling in some of the ingredients of heterogeneous insulators may be the cause of some of the heating of condensers which has been observed by Mr. Swinburne and others.

"Recurring to the subject of duration of contact between two mutually impinging metal balls, we must not assume that this is the duration of electric conductance between them. On the contrary, when the potential of the charge is several thousand volts, there might be separation to the extent of a millimetre or two without cessation of very effective electric conductance. But it will be interesting to find whether, with charges of one or two volts, the exceeding shortness of the duration of metallic contact of mutually impinging balls can suffice to let us sometimes find the electrification of a condenser reversed, after a discharge by impact, even in cases in which the period of the oscillatory discharge with constant resistance is only a few ten-thousandths of a second."

JOY IN CUMMINSVILLE.

An amusing instance of the enthusiasm with which electric railroads are greeted all over the country is furnished by the following item from the Cincinnati *Times-Star:* "The citizens of the Twenty-fourth and Twenty-fifth wards will all unite Saturday night to celebrate the completion of the circuit around Cumminsville of the Colerain avenue electric railroad. They will meet at the intersection of the Colerain and Spring Grove avenues at half-past 7 o'clock sharp. All who may wish to make the trip downtown over the entire route will be amply accommodated, as a sufficient number of cars will be provided by the company to carry all comers. A band of music will head the train and the gentlemen will all bring their horns and the ladies their bells to make the event memorable. This route will bring the citizens of Cumminsville within 25 minutes of the post-office, and its completion opens up a new era for the large and available territory of that suburb."

European Correspondence.

LONDON.

Lighting in Venice.—Village Lighting Plants in Europe.—Russian Telegraph Work.—Accident to Mr. Drake.—Chamberlain and the Chelsea Co.

An alternating current station which was erected at Venice by a Milan company some time ago, has so great a demand upon it for light that it is deemed necessary to still further increase the power. A fourth machine for 80,000 watts will be placed in position. This addition will raise the capacity of the station to 320,000 watts. A short distance from this station the same company is erecting a private installation for a local manufacturer. A large water power is to be utilized, and it is intended to supply electric light and motive power to the establishments in the valley. This installation presents interesting features, since the alternating current will be used both for lighting and power.

The rapidity with which small villages on the European continent take up electric lighting is well illustrated by one or two examples to hand. Such minor Italian villages as Nicastro and Villagio Bella have resolved on the introduction of electric light to be supplied from a single central station erected at Nicastro. For the public lighting in the latter village it is proposed to erect 150 glow lamps of 16 c.p., 40 of 25 c.p. and 10 of 100 c.p., and three arc lamps. Bella is content with 20 glow lamps for its streets.

The distance between the central station of Nicastro and the village is 1300 metres.

Another instance of enterprise on a small scale is Callais, near Nimes, where 465 people dwell, and the streets are lighted by 25 lamps. The motive power is derived from a small waterfall. Besides lighting the village, the current is employed during the day in putting into motion pumps for supplying the neighborhood with water.

The Russian Telegraph Service is contemplating the construction of a telegraph line along the shores of the White Sea to the Norwegian frontier. The present means of communication is a bi-weekly postal service.

Mr. Drake, of the firm Drake & Gorham, of London, has met with a serious accident While superintending the electric lighting work at the New Scotland Yard, he fell into an area fifteen feet deep, and broke his thigh.

The temporary failure of the supply of electricity from the Grosvenor Gallery station is producing effects which will not bear favorably on the electric lighting companies here. Long letters have been sent to the *Times*, complaining about the supply of current by the London Electric Supply Corporation, and this gives Mr. R. Chamberlain an opportunity to attack the Chelsea company. This gentleman asked in the House of Commons a few nights ago, whether the attention of the Board of Trade had been called "to a long continued default of the Chelsea Electric Supply Company to furnish the statutory current of 100 volts, and to the serious loss of illuminating power sustained by consumers in consequence." In his letter he complains that the pressure drops to 98 volts, thereby leaving the place in semi-darkness. On the other hand, the company state that 100 volts is constantly maintained and Mr. Chamberlain is the only customer who complains. They further cite with justice, the fact that the Board of Trade allow a variation of four per cent. above and below 100 volts. One can see at once that the complaints are not well based and that Mr. Chamberlain endeavors to stretch a point when he says that two per cent. variation causes semi-darkness. Unfortunately, the public may follow the error and conclude all is not well with electric lighting.

London, Dec. 20, 1890.

"A Palace of Light.—The Chelsea Electricity Supply Company.—Swansea Lighting.—Electricity and the Census.—Post Office Lighting.—City and South London Railway.

What is well named a "Palace of Light" is the Hofburg of Vienna—the residence of the Emperor of the Austrians—which for the past two or three nights has been one blaze of light. The electric light has been completely installed throughout the place. Incandescent lamps are wholly used. The chief difficulty experienced in fixing these was on account of the strict orders against any alteration of the character and outward appearance of the handsome candelabra in embossed gold which date from the time of Francis I. In the great hall there are twenty-seven of these with fifty-four lights apiece. The difficulty in mounting the fittings was surmounted by inserting small white lacquered wooden tubes, resembling candles at a distance, into the old lustres, each tube being fitted with a movable lamp. The entire installation when completed will consist of 5,250 lamps and nearly 1,800 lights in the entrance halls, galleries, etc. This will no doubt be about the largest installation in any one building in the whole of civilized Europe. The length of wires is said to be fifteen miles. The results of the experimental lighting are said to have filled the spectators with enthusiasm for this mode of lighting. Magnificent ceilings were seen as they had never been seen before and a wealth of color was developed in the famous Flemish tapestries on the walls of the privy council chamber the existence of which had never been suspected.

As the various systems employed by the London companies are subjected day by day to further tests one becomes acquainted with some of the failures in cases of emergency. We referred last week to complaints in the *Daily Press* against the Chelsea Electric Lighting Co. Further information to hand makes one prone to think that something must be out of gear. As your readers may know, this company uses the direct current with accumulators charged at high pressure and discharged direct at low pressure on the mains. A notice has been issued by the company which states that it is the intention to discontinue the supply of electricity between the hours of midnight and four o'clock in the afternoon. This is a measure rendered necessary owing to the continuance of the fog. Naturally enough consumers feel very bitter at being deprived of light when all around is darkened by the fog, and this feeling extends to the vestry controlling the district. At the last meeting of this body a resolution was passed which will injure the reputation of the concern far more than letters in the *Times*. It was to the effect that until this company could supply light night and day, permission would not be granted to extend the area of supply.

Mr. Preece, who occupies the responsible position of technical adviser to many local bodies, has recommended the Swansea Town Council to adopt the tender of Messrs. Crompton for the erection of arc lamps of 2,000 c. p. in the streets at a cost of £23 per lamp per annum.

The Austrian Government is resolved to follow the example set by America in utilizing electrical counters at the next census.

Electric lighting in Postoffice work is gradually growing in favor. Newcastle offices already lighted and the Bristol post-office will soon be supplied in the same way.

Up to date the working of the City and South London underground line has been most satisfactory, the only difficulty being that of carrying the number of passengers desirous of traveling by it. Thirty thousand people traveled by the line on the opening day and since then the rush has at times been so great that the booking of passengers has had to be stopped till the platforms were cleared of those who were waiting. The working has consequently been strained to the utmost and trains have sometimes left with as many standing as sitting passengers; nevertheless there has been but one hitch due to electrical cause and that was merely the slipping out of a connection. As a precautionary measure, however, the traffic is stopped early—at about half-past ten—and all the day on Sundays in order to give time for a thorough examination and inspection of everything.

H. S.

London, Dec. 24, 1890.

Society and Club Notes.

MR. F. L. POPE TO LECTURE BEFORE THE ELECTRIC CLUB.

The next regular meeting of the Electric Club will be held Jan. 22. Mr. F. L. Pope will deliver a lecture entitled "Some Notes on the Electric Railway, Historical, Statistical and Technical." The subject is one of which Mr. Pope has long made a special study. He will handle it in a broadly popular manner so as to make his points clear to the large gathering that may be expected of those who will hasten to enjoy the Club's hospitality that night, and who have hitherto been looking for just such an exposition of the subject.

MASSACHUSETTS ELECTRICAL ENGINEERS AND MECHANICS ASSOCIATION.

At the meeting of the Massachusetts Electrical Engineers and Mechanics' Association, Boston, last week, the following named officers were installed: Past president, John Dean, Jr.; president, James E. Cole; vice-president, Eugene C. McCarthy; treasurer, Charles Toner; financial secretary, George W. Newman; recording secretary, James E. Lynch; corresponding secretary, W. C. Woodward. The committees on the ball to be held in Odd Fellows' Hall the 29th inst. made favorable reports, and it was voted on that occasion to make the finest display of electric lights and lighting that Boston has yet witnessed.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The 53rd meeting will be held at eight o'clock, on Tuesday evening, January 20th, at the rooms of the Institute, No. 12 West 31st street, near Fifth avenue. The session will be devoted to the discussion of the following subjects: Inductance and Its Proposed Unit, the "Henry." This discussion of Mr. Kennelly's paper, postponed from the last meeting, will be opened by Dr. Cary T. Hutchinson. The paper will be found printed in full, and revised by the author, in THE ELECTRICAL ENGINEER, Dec. 24th. Reports of the following Committees will also come up for action: The Standard Wiring Table Committee; Committee on the Value of the "Henry"; Committee on Amendment of the Patent Law. Copies of the reports of the first two Committees will be furnished upon application to the secretary.

Non-resident members who are interested in the above subjects are invited to contribute their views in writing. Gentlemen not identified with the Institute are cordially invited to attend.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

All parties desirious of exhibiting in the hall secured by the National Electric Light Association at Providence, R. I., on the 17th, 18th and 19th of February next, must send in their application at once, as the allotment of space will soon begin. The applications already sent in aggregate nearly all the available space in the hall, and it may be necessary to cut down the applications pro rata.

Appointments, Etc.

APPOINTMENTS, &c.

MR. JOHN H. SHARPE, of the Edison Illuminating Co., in Brooklyn, has been appointed general superintendent of the Nyack Electric Co., Nyack, N. Y.

MR. H. W. BLAKE, late of the Intelligence Department of the Sprague and Edison General Companies, has become assistant editor of the *Street Railway Journal*, with special charge of the electrical department.

MR. A. CHURCHWARD, late of the Crocker-Wheeler Motor Co., has been appointed assistant electrician of the Riker Electric Motor Co., of Brooklyn.

MR. JOHN D. EASTERLIN, under the re-arrangement of the districts of the Southern Bell Telephone Co., has been appointed superintendent of the consolidated second and third divisions, with headquarters at Atlanta, with charge of the united repair shops there.

Mr. JOHN CASSIDY, who has long been in charge of the telephone service of the Sandwich Islands, has been appointed by the government to the supervision of the electric light circuits, etc.

LIEUT. JAMES A. SWIFT, Signal Corps, now on duty at Titusville, Fla., will make a thorough inspection of the Signal Service stations in Florida.

Patent Notes.

EFFECT OF DULL TIMES ON INVENTORS.

As the Inventors' Record in THE ELECTRICAL ENGINEER shows, the number of electrical patents issuing is remarkably well maintained, and the recent financial stringency would seem to have had little effect in electrical fields of invention. But as to the situation, a special dispatch from Washington, of Jan. 8, to the *Evening Post*, says:—"The 'hard times' produced by the McKinley Tariff Act and the backing and filling of the Republican financiers in Congress have told upon even the Patent Office—a quarter where one would scarcely look for a barometer of public feeling in pecuniary matters. The law gives inventors six months, after notice of allowance of their claims, for the payment of the final fee and the issue of their patents. The final fee is $20—a sum which, in the cases of a large number of ill-paid mechanical geniuses, is not so easy to scrape together. So many budding patentees have found the money stress too great for them that the weekly issue has sunk from an average of about 500 letters to something more than 300, and the income of the office from fees is estimated to have fallen off at least 25 per cent. Leading patent attorneys in this city are complaining that business was never so dull before, and that they are hardly making enough to keep their offices running. As times grow easier, doubtless the figures will spring back again. Meanwhile, his enforced leisure, comparatively speaking, will enable the Commissioner to give to the necessary improvements in his office a part of the thought which has hitherto been almost monopolized by the survey of work accomplished. The office is in very bad condition—overcrowded, and ill supplied with facilities. A strenuous effort on the commissioner's part to force upon Congress the recognition of his most pressing needs would perhaps be more fruitful of future good to the service than his ambition to show what wonders can be accomplished with the meagre resources now at his command."

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of January 10, 1891, from New York, Boston and Washington; Pittsburgh, January 9.

NEW YORK.

	BID.		BID.

PITTSBURGH.

	BID.
Westinghouse Electric and Manufacturing Co.	8¾

* Ex Dividend.

WASHINGTON, D. C.—The Board of Electrical Control of the District of Columbia, created by Act of Congress, has organized. It consists of Prof. H. A. Rowland, of Johns Hopkins, Lieut. F. R. Shunk, of the U. S. Engineers, and Mr. A. Rosewater, of the *Omaha Bee*, an old telegrapher.

ELECTRIC RAILROADING IN AUSTRIA.—It is said that an electric road is to be built from Vienna to Buda Pest, a distance of 250 kilometers. The journey now occupies 4½ hours, and it is proposed to do it in 2½. The statement lacks confirmation.

Reports of Companies.

LAREDO IMPROVEMENT CO.

A special dispatch of January 7, from Lawrence, Kan., says: Chas. F. Yeager and B. F. Nicholson were yesterday appointed receivers of the Laredo Improvement Company. Mr. Moore, of Lutcher & Moore, of San Antonio, president of the company, says the assets are $395,000, the actual cost of the real estate and improvements and their electric street-car railroad. He also places their liabilities, including capital stock, at $355,000.

THE RHODES MANUFACTURING CO.

The Rhodes Manufacturing Company, of Philadelphia, made an assignment on January 5. It conveys no real estate. The company was incorporated on the 10th of March last for the manufacture of electric motors. It was stated last week that the authorized capital was $200,000, of which amount it was claimed $170,000 was paid in, made up of machinery, tools, stock, real estate, and patents, the latter of which were valued at $50,000. The company's credit was good. No estimate of liabilities and assets can be formed at present.

HUDSON RIVER TELEPHONE CO.

By the termination of a lease the Hudson River Telephone Company has come into possession of the property and franchise of the New York and Vermont Telephone Company. Formerly the Hudson River Co. confined its business to the main lines around Albany. Several branch lines were leased to other companies, among them the Union, of Saratoga, and the Schenectady, Amsterdam, Gloversville, Hudson, Catskill, and New York and Vermont companies. These leases were given by the Hudson River Telephone Company when it controlled the territory over which the various lines were operated. Subsequently another syndicate was formed, which purchased the leases of all the lines except the Union of Saratoga and the New York and Vermont. There is talk of forming another syndicate to include some of the cities along the Hudson and at interior points.

GLENNS FALLS, N. Y., STREET RAILROAD CO.

At a meeting of the street railroad company held Dec. 22, the following directors were chosen: J. M. Coolidge, B. B. Fowler, W. W. Rowe, of Troy, Samuel Bolton, Jr., Peter McCarty and J. A. Powers, of Lansingburg and H. R. Leavens. The board organized as follows: President, J. M. Coolidge; secretary and treasurer, B. B. Fowler; executive committee, J. M. Coolidge, B. B. Fowler and J. A. Powers. Resolutions asking the State board of railroad commissioners to change the motive power to electricity, and also to increase the capital stock from $70,000 to $120,000 were passed.

THE THOMSON-HOUSTON AND BRUSH ELECTRIC CO'S.

The Thomson-Houston Electric Co., having fulfilled all the terms of its purchase of the Brush Electric Co., has entered upon the management of that valuable property. It is rumored that the affairs of the Brush Co. will be handled in Boston although a large staff with onerous responsibilities will be maintained in Cleveland. The *Boston Globe* of January 3, says:

"A notable change in the directory of the Thomson-Houston Electric Company took place Jan. 1, by the resignation of Mr. S. A. Barton, the organizer of the company and a member of the board since 1882. From 1882 to 1886, Mr. Barton also occupied the position of general manager and treasurer; at which time he removed to Chicago to build up a Western business. On returning in the winter of 1889 he organized a central purchasing department for the various Thomson-Houston interests, and has recently assented to taking the presidency of the Brush Electric Company at Cleveland, O., and re-organizing the same, but will not change his residence." In connection with this change of work, it is further understood that to Capt. Eugene Griffin will fall a large part of the work, as the right hand man of Mr. C. A. Coffin, under the readjustment of duties at the Thomson-Houston headquarters, and that, in turn, some of Capt. Griffin's old duties will devolve on Mr. O. T. Crosby.

DIVIDENDS.

MILFORD, MASS.—The Milford Electric Light & Power Co. has declared a dividend of 2 per cent.

STOCKS AND BONDS.

RICHMOND, IND.—The Richmond Street Railway Co. has filed a mortgage with the Union Trust Co., of St. Louis, and J. B. Dougan, a local banker, for $200,000 to secure that amount of thirty year $1,000 bonds at 6 per cent. Among those interested are J. C. Shaffer, the street railway magnate of Indianapolis, and Russell Harrison, son of President Harrison. The road is a very successful one.

THE UNION TELEPHONE CO., of Saratoga Springs, N. Y., has passed into the control of the Hudson River Telephone Co. A new local company will be formed January 14. It is proposed to spend $5,000 in improving the system.

ANGOLA, IND.—The tax-payers are seriously considering the advisability of the city purchasing the electric light plant established by private parties. The electric company is willing to sell if it receives dollar for dollar of its investment, but an offer of eighty cents for a majority of its stock by outside parties has been refused.

WOONSOCKET, R. I.—The Providence *Financial News* says Woonsocket Electric stock has recently, in a few cases in Providence, sold at $95, and adds that it is in good demand in Woonsocket at that price, will probably sell higher, and would be more active in Providence if dealers were fully acquainted with its merits.

MAYOR GRANT ON NEW YORK CITY WIRES.

In his annual report, Mayor Hugh Grant says:—The work of removing the poles and overhead wires has been continued without interruption during the past year, and in every instance in which the companies have contested the right of municipal Government to compel the removal of these poles and wires the city has been successful. The Board of Electrical Control during the past year has constructed for the reception of telegraph and telephone conductors 178 miles of single duct in nine miles of street trench, making a total construction of telephone and telegraph subways of 697 miles of duct in 38 miles of street trench. There have been constructed 132 miles of duct in 39 miles of street trench for electric light conductors, making for electric light service constructed up to date 647 miles of duct in 85 miles of street trench. There have been placed in the subways 10,150 miles of telephone and telegraph wire and 340 miles of wire for electric light service, making in all now in the subways, telephone, telegraph, and electric light wires, 23,797 miles. There have been removed during the year 1,361 poles and 18,949,645 feet of overhead wire.

At the present time many of the departments operate separate systems of electric wires, which are largely maintained through separate cables. In several of the large cities of the United States a central electrical exchange, through which intercourse can be had between the different departments of the city Government, is in existence, under the control of the local authorities. It is a question for serious consideration whether such a system should not be adopted in this city. If it should be ultimately concluded to adopt such system it could be extended to enable the city to furnish its own electric lights.

THE BITE OF AN ELECTRIC BUG.

The following dispatch from Philadelphia of Dec. 28 is of very peculiar interest as presenting another argument against overhead wires:

"Physicians and medical students have been studying with great interest a case without a parallel, so far as is known. Little Mamie Lurker, walking in Girard avenue a few days ago with her aunt, suddenly stopped, and, putting up her hands to her face, screamed, "I am shot." The aunt seized the child's hands and immediately staggered back as if she had received an electric shock. A crowd speedily gathered and a man crushed with his foot a peculiar bright-hued bug, bottle-shaped and hard-shelled, which, falling from a wire overhead, had dropped on the girl's face and stung her. A bright crimson spot, in Mamie's cheek showed where the bug had made the wound and evidently inoculated her with the electricity with which it was charged by being in contact with the wire. Little would have been thought of the accident had it not been for the peculiar symptoms of the girl, who was nervous and uneasy and whose grasp sent an indefinable tingling sensation to the hands of everybody who touched her. Dr. De Beust diagnosed the case as bullis, or vasicular poisoning, and administered the remedies usual in cases of that kind. To his astonishment, however, the bright-hued sore on the cheek was followed by other bright-hued eruptions on every part of the body, each one emitting the same peculiar tingling sensation when touched. In his opinion the bug was of a Brazilian species brought to this country in the year of the Centennial. The insect in itself is not known to be poisonous and is distinguished for its peculiar bottle-shaped appearance.

"The patient is now considered out of danger, after unremitting attention on the part of the physician, but still suffers from the inocculated electric bite."

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JAN. 6, 1891.

Accumulators :—

Electrode for Secondarg Batteries, S. C. C. Currie, 444,392. Filed June 10, 1890.

The electrode is composed of the salt or salts of a metal or metals and is provided with an integral tough and compact or dense supporting-rim of the same material or materials, distinguished from the active portion of the electrode.

Alarms and Signals :—

Electric Annunciator, A. Hormel, 444,245. Filed July 29, 1890.

An electro-magnet on the upper shank of a frame has an armature pivoted to the back part of the frame, the armature having a knob or hook on its free end with an elbow-lever having an aperture and pivoted to the lower shank of the frame, so that the lever is kept in an upright position by the knob or hook of the armature ; a lifting lever serves to raise the elbow-lever when it is released from the armature.

Signal-Box, J. C. Wilson, 444,144. Filed Jan. 14, 1888.

Applicable to signal systems including telephone circuits.

Claim 5 follows :

In a signal-box, a signal-transmitter and answer- back bell, a telephone, a shunt-switch for said answer-back bell automatically closed by the removal of the telephone, a normally-open ground branch leading from the signaling circuit for the telephone, and a switch for closing it automatically when the door of the box is opened.

Conductors, Conduits and Insulators :—

Man-Hole for Underground Electric Conduits, W. H. Hart, 443,992. Filed Mar. 22, 1890.

Designed and constructed to preclude the entrance of gas into the man-hole, and to prevent the shocks and jars due to passing vehicles from injuring the walls of the man-hole and impairing the joint between the walls and the cover.

The base or floor is constructed of material impervious to gas and moisture ; double walls are built upon such base and between them is interposed a filling of composition impervious to gas and water. A yielding gasket is interposed between the cover section and the walls.

Tightening Device for Suspended Electric Conductors, D. Mason, 444,005. Filed May 28, 1890.

Claim 1 follows :

A suspended electric conductor having a tightening device interposed therein for tightening or loosening the same, substantially as and for the purpose set forth.

The device shown and described consists of a winding drum to which the conductor is attached so as to be wound or unwound ; the drum is provided with a cog or ratchet and a detent for engaging and retaining it. The device is attached, preferably, to a hanger attached below an insulator.

Tightening Device for Suspended Electric Conductors, D. Mason, 444,006. Filed May 28, 1890.

A spring is employed to keep the conductors stretched, instead of a winding drum as in No. 444,005, above.

Claim 3 follows :

A suspended electric conductor having interposed therein a spring acting to tighten the conductor, for the purpose described.

Electric-Wire Insulating-Cleat, J. S. Potter and D. J. Cartwright, 444,317, Filed Aug. 16, 1890.

The cleat, which is formed in two parts secured to the wall or ceiling by screws passing through them and clamping them together, has the ducts or perforations tapered so as to permit the insertion of wedges to secure the wires in position.

Molding for Electric Wiring, G. Cutter, 444,377. Filed July 21, 1890.

In order to prevent the charring or carbonizing of the partitions in a molding for electric light wires—which is usually formed entirely of wood, and which is liable to cause short-circuiting—the grooves of the moulding are separated by longitudinal partition-strips of insulating material

Dynamos and Motors :—

Dynamo-Electric Machine, A. G. Holcombe, 444,067. Filed Sept. 17, 1890.

The invention is particularly applicable to alternate-current generators, and relates to the construction of machines of the class in which currents are generated by revolving electro-magnetic pole-pieces, without coils, in proximity to fixed armature coils, the exciting coils also being stationary.

Electric Motor Attachment for Reed Organs, L. K. Fuller, 444,169. Filed July 19, 1889.

Modification of the pneumatic and mechanical devices of reed-organs for the adaptation of electric motors to actuate them, including intermediate speed-reducing gearing, and including also means whereby the performer may regulate the force of the electric current supplied to the motor.

Electric Motor, C. J. Van Depoele, 444,188. Filed March 22, 1889.

Improvement or amplification of electric motor described in patent No. 443,980, Dec. 30, 1890 (see *Inventors' Record* in the ELECTRICAL ENGINEER, Jan. 7, 1891).

The present invention comprises a motor including the three elements shown in the patent above referred to ; but the induction coil for the armature instead of being the primary circuit of an inducting system is arranged in a secondary relation to the field magnets, and therefore the armature becomes a tertiary induction system ; the current in the coils of the field magnet produces a secondary current in the induction coils surrounding or embracing the armature, and such secondary currents in the induction coil induce tertiary currents in the armature, which serve to establish the requisite poles therein. The poles thus produced in the armature are located by providing a definite path or paths for the currents circulating in it, as described in the previous invention above referred to.

Lamps and Appurtenances.

Electric Arc-Lamp, A. W. Reppy, 444,104. Filed Sept. 27, 1890.

The invention relates particularly to the form of the carbons and the mechanism for feeding them, and consists chiefly in the combination, with two rotary carbons mounted edge to edge, of means for rotating and feeding them at the proper relative rates of speed.

Claim 1 follows :

In an arc lamp the combination of the two rotary carbon discs having the pinions of unequal diameters, the stationary rack engaging the smaller pinion, and the rack carried by the carbon having the smaller pinion, said rack engaging the larger pinion, whereby the carbons rotate at unequal rates of speed.

Electric Arc-Lamp, J. J. Skinner, 444,154. Filed April 27, 1886.

Relates to the class of arc lamps in which the feed is controlled by an electro-magnet independent of the one separating the carbons, the feed controlling magnet being either in the main circuit or in a shunt, according as the lamp is used in a single circuit by itself of forms one of a series.

The devices comprise a clamp pivotally connected with the armature of the feed-controlling magnet at one side of the carbon rod, and an independent lever connected at an intermediate point of its length with a fulcrum, and having one arm in position to be engaged by the armature of the feed magnet and its other arm in position to engage with the free portion of the clamp.

Support for Electric Lamps, J. Chase, 444,330, Filed May 17, 1890.

A device designed to hold out-door arc lamps firmly in position during high winds, avoiding swinging or vibration ; also to secure perfect electrical contact during the raising or lowering of the lamp.

Electric Switch, C. E. Wilson, 444,874. Filed Sept. 18, 1890.

A design and construction for a positively acting switch for incandescent light systems, the parts of which are all of such simple construction as to be punched out and assembled at small cost.

Metallurgical :

Magnetic-Ore Separator, C. Q. Payne, 444,223. Filed Aug. 19, 1890.

Designed to obtain a more perfect concentration of lean or low-grade iron ores. The electro-magnets are constructed in the main with a view of securing a better arrangement of the lines of force in the magnetic field in which the separation takes place.

Claim 1 follows:

In a magnetic separator, two segmental ring-shaped pole-pieces magnetized, respectively, by positive and negative polarity and placed concentrically, so as to constrain the lines of force to occupy positions normal to their adjacent surfaces.

Miscellaneous :—

Electrical Range-Finder, B. A. Fiske, 444,217. Filed June 25, 1890.

Invention embraces the determination of a fractional portion of a conducting body bearing in length a ratio to the angle included between two lines of sight directed upon a distant object, and simultaneously causing a disturbance in an electrical balance including said body in its circuit proportional to the resistance of said fractional portion, and, observing the difference in potential in the circuit due to the disturbance. Provision is made for reading directly from a suitably marked scale of an electrical measuring instrument constructed to measure the amount of the disturbance.

Electric Agricultural System, E. M. Bentley, 444,265. Filed May 11, 1888.

The invention relates to a system of the same general type as that shown in the same inventor's patent number 382,941 of May 15, 1888, which included two supply wires suspended upon opposite sides of a field and an electrically actuated machine driven forward and backward across such a field and provided with electrical connection with the two opposite wires. The present invention consists in arrangements for applying the system above referred to to a large number of fields to be operated simultaneously or successively. It consists partly in details of devices for electrical connection of the machine and the supply wires and partly in a specific form of machine by which a plow or similar agricultural instrument may be operated.

Registering Mechanism, or Counter Actuated by Electric Currents, R. Jewell, 444,358. Filed June 20, 1890.

An application of electro-magnetic mechanism to actuate a registering or counting machine embracing one or more dials.

Railways and Appliances :—

Brake for Electric Cars, B. L. Randall, 444,110. Filed Sept. 11, 1890.

Consists in mechanism to enable the driver when applying the brake to cut off the power automatically and simultaneously. The shutting off of the current is governed directly by the action of the brake.

Current-Collecting Device for Electric Railways, R. M. Hunter, 444,397. Filed Sept. 24, 1890.

Consists essentially of the employment of iron wires as working conductors—suitably connected at intervals with supply conductors—and of trolley wheels of iron in contact with the poles of electro-magnets carried on the trolley-pole ; the motor current passing through the electro-magnet ; with a view of securing the best possible contact between the trolley-wheels and the working conductor.

Telephones and Apparatus :—

Signaling Apparatus, I. H. Farnham, 444,108. Filed Aug. 20, 1890.

Relates to telephone circuits of the class in which a number of stations are connected upon one line, and particularly adapted to metallic circuits. The invention includes an electro-magnetic call-receiving device located at each station in a permanently closed bridge or branch of the circuit, and a call-sending generator at each station in a normally open bridge or branch of the circuit, parallel to the above mention closed bridge or branch, and means for closing the generator circuit to send an out-going signal, and for simultaneously increasing the resistance of the parallel bell-branch circuit at the same station.

ELECTRICAL PATENTS EXPIRING IN DECEMBER, 1890.

Telegraph Cut-Out, W. G. Lion, No. 145,064, December 2, 1873. *Telegraph Register*, W. H. Sawyer, No. 145,128, December 2, 1873. *Non-Freezing Battery*, E. H. Ashcroft, No. 145,143, December 9, 1873. *Electric Signaling Apparatus for Railways*, F. L. Pope, No. 145,308, December 16, 1873. *Telegraph Transmitter*, D. Hermann, No. 145,567, December 16, 1873. *Lightning Rod*, J. Drew, No., 145,851, December 23, 1873. *Telegraph Insulator*, Fox and Heston, No. 145,997, Dmber 30, 1873.

"THE SCHOOL BELL."

The above is the title of an excellently printed and cleverly edited newspaper of 8 pages, issued by the young folks at Arlington, N. J. We are indebted for a copy of it to Mr. George A. Wiley, of the Standard Underground Cable Co., an old resident of Arlington. The paper is full of pretty little articles and poems, and we wish to commend specially the article by Master F. E. Suderly, on "Electricity and its Uses." When the coming generation of citizens can show the appreciation of the benefits of electricity that this article evinces, electricians need have no fear as to the future of their art. There is also a good essay on "Journalism," by E. P. Fredericks.

NEW YEAR WISHES.—The London *Electrical Review* has issued a neat card of New Year wishes to its contemporaries. Up in one corner is a projector, whose brilliant beams suggest the fierce white light of publicity that a modern journal throws upon things within its ken.

Legal Notes.

PAYMENT FOR STREET PAVING BY STREET RAILWAY COMPANIES.

Notice has been served by the city, on the Omaha Motor Line Co. to the effect that a suit is to be begun in the Superior Court to force the company to pay $7,000 due for the paving of street intersections over which the line runs. The contention is that under the State law the company is liable for the paving of their tracks and for a foot outside. The motor company claims that the cars do not make any wear on the streets, all the wear falling on the tracks.

I. A. BARNES vs. CARPENTER-NEVINS ELECTRO-HEATING CO.

Isaac A. Barnes, the attorney, is the plaintiff in a suit soon to be brought against the Carpenter-Nevins Electro-heating Company, to recover $10,500. About six months ago, Barnes, after hearing glowing accounts of the company's success from the lips of Frank W. Nevins, secured 50 shares of stock, giving in exchange $500 and real estate which he says was worth $6,000. He also says that Nevins represented that the company was magnificently prosperous, and made other misrepresentations: for instance, that the wire coiling, an important part of the apparatus, would last 10 or 15 years, when, in fact, its life is only about two months. Barnes sues to recover the property and money invested and $4,000 damages additional.

BRUSH-SWAN CO., OF N. E. vs. BRUSH ELECTRIC CO.

In the action of the Brush-Swan Company of New England against the Brush Electric Company of this city, Judge Coxe, of the United States Circuit Court, New York, on Jan. 2, granted an order permitting the defendants to sell their apparatus as fast as manufactured, and requiring them to pay over to the plaintiff 20 per cent. of such sales. The plaintiff is required to file a bond in $25,000, and in the event of their failing to do so, the percentage must be paid into the registry of the court and remain there to await final action of the courts.

THE GOVERNMENT TELEPHONE CASE.

The annual report of the Attorney-General of the United States, dated Dec. 1, 1890, contains the following paragraph:

"As foreshadowed in the last report, the taking of evidence in the case of the United States against the American Bell Telephone Company and Alexander Graham Bell was commenced very shortly after that report was made, and has been prosecuted diligently ever since. The evidence on behalf of the Government has not as yet been completed. The defendants decline to agree, and the court declines to order that the testimony be taken by a stenographer. The cross-examination of the government's witnesses is greatly protracted, with the probable effect of delaying the progress of the case so that no decree can be reached before the expiration of the defendants' patent. Seventy days have been occupied by the defense in the cross-examination of one witness, and the cross-examination is still going on at the date of this writing. The case will be pushed as rapidly as possible under the circumstances."

At Boston on January 6 before Judge Colt, the plaintiff moved for an order of court that the time allowed for taking testimony be extended in this case to April 1. There was now a hearing upon the motion, and the judge ordered the time extended to April 1. C. S. Whitman for the plaintiff; G. L. Roberts for defendants.

W. TAYLOR vs. NEWARK, O., AND GRANVILLE ELECTRIC ROAD.

At Newark, O., on January 5. Judge McElroy rendered his decision in the case of Waldo Taylor against the Newark & Granville Electric Road. The case has attracted widespread attention. Taylor asked for an injunction restraining the issuing of stock on bonds and applied for the appointment of a receiver, setting up the usual charges in such cases. After a lengthy review of the case the application for an injunction is refused, the petition dismissed and the motion for a receiver overruled.

A REVIEW OF RECENT STORAGE BATTERY LITIGATION.

With regard to recent storage battery litigation and the statements made in regard thereto, Mr. D. H. Bates, president of the Electrical Accumulator Co. says, of the report of Judge Brown's decision at Cleveland, O.:

Meanwhile, the suits instituted by The Electrical Accumulator Company against the Brush Company in the Ohio District to determine the respective standings of the Faure and Brush patents had, owing to dilatory proceedings instituted in great part by the defendants, progressed no farther than the preliminary pleadings, and the merits of the case have not been brought into question, and no testimony has been taken. It is in this case, that Judge Brown has made an interlocutory decision, involving three questions of law and fact, as follows:

The Accumulator Company applied to the court for leave to dismiss the two interference suits, alleging that, owing to the construction placed upon the Faure patent by Judge Coxe, there no longer remained any interference. In one of these cases, namely, the one in which the Faure patent was in interference with the Brush patent, 337,298, the court decided the motion in favor of the Accumulator Company; in the other case, Judge Brown held that the question of the expiration of the Brush patent, by reason of the prior grant of the Italian patent, could not be decided until after full hearing and hence sustained the demurrer of the Brush Company to that portion of the Accumulator Company's bill, leaving the case to proceed on its merits.

In the same case the Accumulator Company filed a supplemental bill, setting up that since the disclaimer filed to the Faure patent, there was no longer any interference between the first claims of the Faure patent and the formerly interfering claims of the Brush patent. The Brush Company filed a demurrer to that supplemental bill, on the ground that this question could not be tried in that case, and Judge Brown also decided this question in favor of the Accumulator Company.

The facts are, therefore, that in the recent case three points have been decided, two in favor of the Accumulator Company and one in favor of the Brush Company, leaving the case still to be tried on its merits.

The Accumulator Company claims, and its claims are based upon a long and wide experience in the business, that no form of storage battery so far made has proved or can prove successful, except that made by the Faure process where the active material is supplied to the support plate in the form of a paint, paste or cement prior to immersion in the battery fluid, and that where, according to Judge Lacombe's construction of Brush's experiments, a perfectly dry power is compacted upon the grid by a hydraulic pressure and no fluid added until the plate goes into use in the battery, the absorption of the fluid by the active material causes it to expand and to exhibit a tendency to disintegrate, such tendency being accelerated on the occasion of each succeeding charge and discharge. In other words, a battery so constructed is not durable and breaks down when subject to any but ordinary strain.

PUMPELLY STORAGE BATTERY.—Wm. J. Brown has begun suit at Detroit on a judgment against the Pumpelly Storage Battery & Electric Motor Co., of Illinois, for $15,000 damages.

A TRIAL FOR EMBEZZLEMENT.—A special dispatch from Sioux Falls, S. D. of January says: The trial of E. J. Mannix, ex-manager of the Western Union Telegraph office in this city, was begun yesterday. The charge is the embezzlement of $3,472. The Western Union is making a bitter fight to secure the conviction of Mannix, who is resisting with able attorneys. Evidence is being introduced by the Western Union people to show that a conspiracy existed between a dozen telegraph points in South Dakota, and that Mannix was one of the principal conspirators.

UNION OF ALUMINUM AND GLASS.

A special dispatch from Cincinnati of Jan. 8, says: Bradford McGregor, the mechanical expert of this city, has succeeded in uniting aluminum with glass, and he claims to be the first who has done so. A large piece of the aluminum with a glass tube in the centre was turned in his lathe, and it was impossible to detect the joint where they united. Heretofore no metal could be made to unite with glass in which the contraction and expansion were the same, and it is claimed that this will create a revolution in the way of reducing the cost of incandescent lights, as it will take the place of platinum, which costs $320 a pound, while the new discovery will cost only $10.

ANNUAL ELECTION OF THE MAGNETIC CLUB.

The annual meeting of the Magnetic Club was held January 8. President Dealy, though nominated, declined re-election and anticipating that the members would favor and second his desires, made a requisition in due course upon the W. U. superintendent of supplies for the services of Mr. E. C. Cockey as president. The nomination being made, Mr. Cockey's election was enthusiastically and unanimously made. The vice-presidents are W. H. Baker, W. L. Ives, M. J. O'Leary and T. E. Fleming; secretary, G. F. Fagan; treasurer, J. Brant.

HOLTZER-CABOT CO.

The above enterprising Boston concern have issued a very handsome calendar, the engraving upon which is after one of the best of Landseer's Highland deer pieces. It shows also the fluctuations of the moon. It is worthy mention that the company issues a remarkably fine catalogue of its productions, which should be applied for when writing for a calendar.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"Be liberal with your publisher; candid with your public, and Heaven will send you customers."

THE "CHAMPION" PRIMARY BATTERY.

THIS is the name of a new primary battery of the sal ammoniac type which has recently been improved by Mr. C. J. Hirlimann, of No. 91 Greene street, this city, one of the original manufacturers of the Leclanché batteries in this country. The accompanying engravings illustrate the new "Champion" cell, which is made up in two distinct patterns; the difference, however, lying only in the form of the zinc. Thus, it will be seen that in one form, Fig. 1, the zinc consists of the ordinary rod zinc, while the other has a large surface of corrugated sheet zinc, Fig. 2.

FIG. 1.—ROD ZINC OF CHAMPION BATTERY.

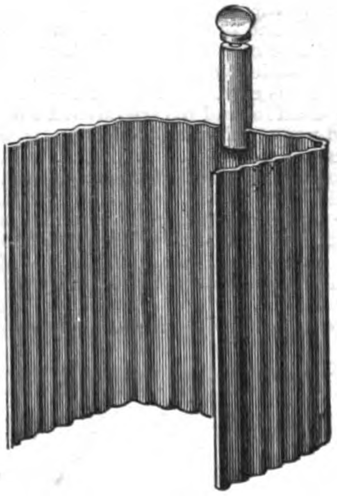

FIG. 2.—CORRUGATED ZINC OF CHAMPION BATTERY.

When the rod zinc is employed the battery is most suitable for telephone work, and where a constant output of energy is required, while the corrugated zinc is used where large quantities of current for a short time is the desideratum, as in gas lighting work, electric bell ringing, etc. In further support of the merits of the battery a measurement of the cell by the well-known electrician, Mr. George d'Infreville, of this city, is given as follows: Electro-motive force, 1.4 volt; internal resistance, .17 ohm; current, 8.3 amperes.

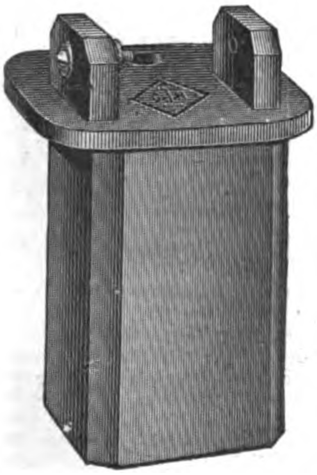

FIG. 3.—CARBON RESERVOIR OF CHAMPION BATTERY.

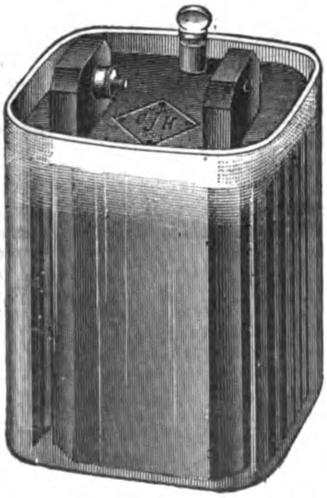

FIG. 4.—COMPLETE CELL OF CHAMPION BATTERY.

It is needless to say that if these figures can be depended upon uniformly in all the cells of this battery manufactured, the Champion battery will be a valuable acquisition to the trade, and Mr. Hirlimann, so far from having any doubts in this regard, states that by a special process through which the carbons are put after baking, there will, if anything, be an increase in the amperage of his cell beyond the official report above given.

The carbon reservoir, Fig. 3, is quadrangular in shape and charged with ingredients under a secret formula, and is provided with a neat top, fitting closely into the glass jar, to prevent evaporation and facilitate sealing, as shown in Fig. 4.

The Champion battery, both with rod zinc and corrugated zinc, will be on sale at all prominent supply houses in this country, and patents in Europe, we understand, are applied for.

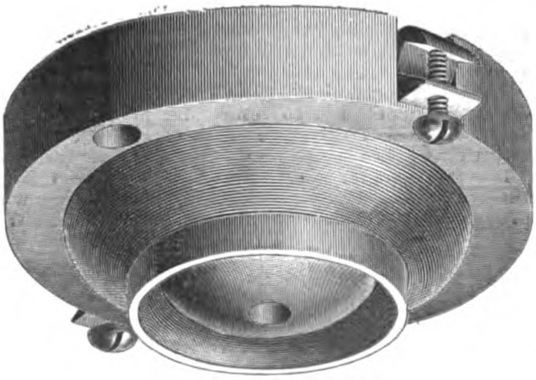
THE PAISTE IVORY CHINA SWITCHES.

H. T. PAISTE, manufacturer of the well known Paiste specialties, is now placing on the market a switch, the handle, cover and base of which are made of English ivory china. The switches are very neat and artistic, and designed for fine residence installations. They are furnished in all colors, to match wall paper and felts. Those with the dull gold finish are particularly fine. The demand for these goods has been so great that 500 are being imported weekly. One noticeable feature is that the cap screws on the base with a thread cut in the china. Mr. Paiste claims for these switches that they will always present a fine appearance, as the china cover will not tarnish, as all metal caps do in time when exposed to atmospheric changes.

THE PAISTE IVORY CHINA SWITCH.

A NEW PETTINGELL, ANDREWS CEILING BUTTON.

WE illustrate in the accompanying engraving a new ceiling button which is being introduced by the Pettingell, Andrews Company of Boston. This button does away with the necessity of cutting the wires and making a soldered joint to the flexible cord.



NEW FORM OF CEILING BUTTON.

As will be seen the cord is put through the hole in the centre of the button and is fastened by screws to the inside ends of the clamps. The clamps themselves are for the reception of the main branch wires and are put in circuit like the ordinary K. W. cut out.

W. H. GORDON & CO.

W. H. Gordon & Co., 115 Broadway, carry a full line of the Star Electrix specialties. The new socket is going like hot cakes as the construction men seem to appreciate the fact that this socket can be connected up in a short time. It is only necessary to loosen two screws to get at the connections.

A GOLD MEDAL FOR "INTERIOR CONDUITS."

The recent demonstration and tests of the conduit system of wiring made by the Interior Conduit & Insulation Company, of New York, in the city of Chicago, before the city authorities, electrical experts, insurance representatives, and later before the Illinois Chapter of Architects, were very elaborate in detail, and were the means of convincing all who were fortunate enough to be present of the superiority of the system for electric light wiring. Prof. John P. Barrett, superintendent of city telegraph of Chicago, endorses the system as follows:

CHICAGO, ILL., Dec. 24, 1890.

INTERIOR CONDUIT & INSULATION CO., NEW YORK,

Dear Sirs:—

After careful examination, I beg leave to say I thoroughly endorse the system of the Interior Conduit & Insulation Company for inside wiring. I further would state that the method of running the two branch wires in a single tube for incandescent electric wiring is approved by me, and I will cheerfully pass any electric installation that is equipped with this system, believing it to be the safest method of interior wiring yet devised.

The appliances of the system are worked out in a manner which insures not only safety but easy accessibility at all times.

Yours respectfully,
J. P. BARRETT, Supt.

P. A. Sowden, superintendent of surveys, Chicago Fire Underwriters Association, was so much pleased with what he saw that he wrote as follows:

INTERIOR CONDUIT & INSULATION CO., NEW YORK,

Dear Sirs:—

I have also examined the system of the Interior Conduit & Insulation Company, and agree in every respect with Mr. J. P. Barrett, and highly recommend your system of interior wiring.

T. A. BOWDEN,
Supt. of Surveys,
The Chicago Fire Underwriters Association.

The Interior Conduit & Insulation Company have recently received a gold medal, first award, at the Mechanics' Fair Association, of Boston, Mass., for their admirable system.

TEYGRAPH V. DUSMILKCOW.

The above is not the name of any recent distinguished arrival from Russia, but is the composite appellation lately assumed and worn proudly by the aggregation of talent that comprises the staff of the progressive Electrical Supply Co. in Chicago. It includes all the letters in his respective surnames, and, as will be seen, presents at once suggestively and graphically the peculiar combination that Chicago fascinates the visitor with, of modern inventions and facilities, alongside the most innocent of rural occupations. In business this energetic gentlemen are hustling like ten little niggers, and then on going home to dine in the evening they beguile his pastoral hours in the suburbs by milking cows. As an accompaniment for their composite name, this accumulated individual has sent us also their composite photograph, which "represents us as we are," he says. The portrait is strikingly attractive in its blend of youthful, manly beauty, with the chiseled serenity of wise old age, due to the fact that the combined years of the nine and his umpire reach about 250. There is also something peculiarly Chicagoan in the keen alertness of the upper part of his face and the soft tenderness that plays around the lower part of their physiognomy. The motto under the portrait is as novel and original as the method thus adopted of sending New Year wishes, while the verses prove that another Sweet Singer has risen in the West.

THE HUNT ENGINEERING CO.

The Hunt Engineering Company, of Brooklyn, N. Y., was incorporated on January 1st, 1891, with a capital of $30,000, the incorporators being George W. Hunt, Albert E. Rich and T. Leeds Waters, all of Brooklyn, and the directors for the first year, Hiram W. Hunt, De Witt N. Cole, George W. Hunt, Albert E. Rich and T. Leeds Waters. The company have moved from their old offices, 177 & 179 Montague street, into new quarters, taking a commodious three-story building at 238 Washington street, which will give them every facility for carrying on their rapidly growing business. They have recently brought out a new improved lamp socket to fit either a Thomson-Houston or a Westinghouse lamp. Messrs. Alexander, Barney & Chapin, of New York, have taken the general agency for this socket.

The company have also under course of construction several new and approved snap switches and other appliances, which they will manufacture and keep in stock, and for which there will doubtless be a ready demand. The Hunt Engineering Company have done construction work for isolated plants and central stations from Brunswick, Maine to Charleston, S. C., averaging about 1800 lights per month, and start in on the new year well equipped in every way for a large and prosperous business.

MORE CHANGES ON "THE ELECTRICAL WORLD."

The following notice in *The Electric Age* of last week will interest a very large circle of electrical readers:

> Mr. Walter T. Hunt, who for the past seven years has been manager of the advertising department of our contemporary, the *Electrical World*, has severed his connection with that paper and assumed a like position with *The Electric Age*. Mr. Hunt is so well known in the electrical trade that it is hardly necessary now to formally introduce him.

This news will probably not surprise anyone who has watched the course of events during the past year in electrical journalism, and Mr. Hunt is to be heartily congratulated on making this change of base while he can still point to the evidences of his good work and to the success he achieved in the special sphere of labor that he now deems it prudent to quit. A more loyal, energetic and wideawake advertising agent than Mr. Hunt cannot be found in this city, and though he can only at this juncture carry his reputation and his friends with him, if nothing else, he may depend upon it that before long a large share of his old business will naturally have followed him, too. The fault will not be his if it doesn't, and he is fortunate, moreover, in being associated with the Messrs. Taltavall, who have already shown their ability, before enlarging their field, and issuing also their electrical journal, by conducting the brightest and best telegrapher's paper ever seen in America. Mr. Hunt will be accompanied in his new departure by the wishes of many who, like ourselves, have watched his career, and know the sterling stuff he is made of. He may count on finding his services appreciated ungrudgingly and without any of the sneering discouragement that often besets honest endeavor and takes the heart out of even the best of us. Mr. Hunt, we understand, is Vice-President and Manager of the Advertising Department of the *Age*.

On Saturday evening, January 10, Mr. Hunt tendered a number of his journalistic friends a dinner at Martinelli's, in recognition of the many expressions of kindness and good will that had reached him from them on the announcement of his change. The evening was spent very pleasantly, and wound up with an hour at the Electric Club.

MR. E. T. COPELAND.

Mr. E. T. Copeland, for the past 12 years general agent of the New York Safety Steam Power Co., announces his establishment of new quarters at 106 Liberty street, corner Church, with superior lines of steam engines, boilers, etc. He invites customers old and young to visit his sales and exhibition rooms.

MR. J. F. MORRISON.

This gentleman, so well known in connection with various electrical enterprises, has decided, for the present at least, to close up his business connections with the various Baltimore enterprises with which he has been connected. Probably the best known among these is the Southern Electric Co., which was established by Mr. Morrison as a supply company in 1879. In 1882 Mr. Morrison associated with himself Mr. D. H. Tuxworth, of Baltimore, the firm carrying on business under the old name. For the past six years other enterprises have so claimed Mr. Morrison's attention that the time devoted to the interests of the Southern Electric Co. was necessarily very limited. He has therefore finally decided to sever his connection with the company, which action took effect January 1st. Mr. Tuxworth assumes all the responsibilities of the Southern Electric Co. from that date.

EDWARD R. KNOWLES, C. E.

Mr. Knowles, who has had a practical experience in various branches of engineering and patent matters for over 18 years, and particularly in electrical work for ten years, has opened an office recently at 181 Broadway, this city, for the transaction of a general expert engineering business. He will undertake any professional work falling within his field, and is competent to begin with the inventor's crude idea, help him work it up, get him a good patent, place the device on a practical working basis, and offer good advice as to further development or as to fighting off infringers. Having known Mr. Knowles throughout his electrical career, we do not hesitate to recommend his services highly.

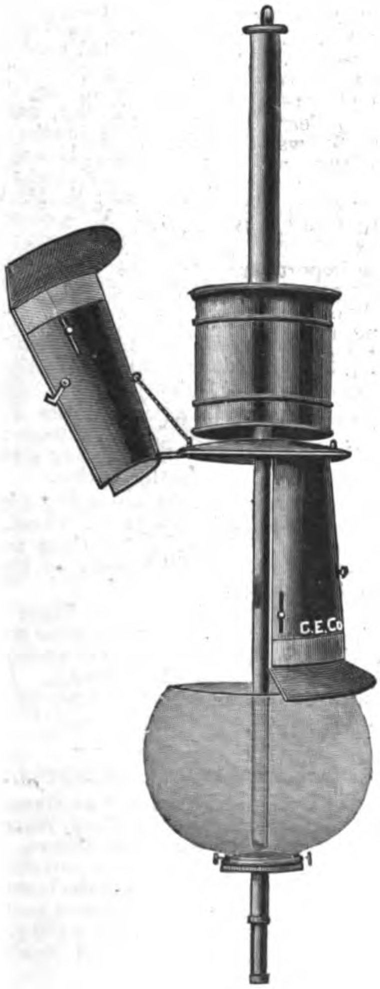
THE COMMERCIAL CABLE CO.

We are indebted to Mr. George G. Ward, general manager of the Commercial Cable Co., for a copy of the handsome big calendar issued by his company. It is in the diamond shape they have adhered to, and the calendar tablet is prefaced with a little greeting in keeping with the season. At the back of the tablet are several fly leaves giving a variety of information likely to be of use to those who use ocean cables.

THE ROBERTSON CARBON PROTECTOR.

The cut shows an ingenious device for protecting carbons and carbon rods from the effects of sleet and snow. The protector is made of galvanized sheet-iron and japanned, and is strong enough to withstand a great deal of hard usage.

At the bottom is an extension feature that permits the protector to be adjusted to almost any size of lamp, and the cut shows one side thrown up to allow the trimmer to give the lamp necessary attention. The lower flange is also shown partly extended. Several hundred of these protectors have been in use in Minneapolis for some time and have given perfect satisfaction. The device can also be used as a spark arrester.



The Robertson Carbon Protector,

The Central Electric Company, of Chicago, are introducing the article.

THE WHELESS CONDUIT RAILWAY SYSTEM IN A SNOW STORM.

The operation of the electric roads during the late snow storms was closely watched. Reporting the state of affairs at the National Capital the *Washington Post* says of the Wheless system: "The conduit system made the best showing during the snow-storm of Friday. Although the conduit was filled with snow and sleet, the current was not dissipated. * * * The conduit line did not miss a trip during the storm."

MUNICIPAL LIGHTING PROPOSED FOR QUINCY, MASS.

Mayor Fairbanks, of Quincy, in his annual address says:—"Light has become a necessity, and there is no true business reason why a city should not only have the right of furnishing light as a protection to travel on its highways, as an aid to its police force, but also to supply its surplus to private citizens. I am aware of the many obstacles apparently in the way, but I think the council can render important service to the city by studying this problem, and become acquainted with the steps being taken in other cities to accomplish this one object of properly lighting our city."

PERRET MOTORS FOR PUMPS AND ELEVATORS.

A 20 h. p. Perret multipolar low speed motor has just been placed in the Hamilton Club Building, Brooklyn, to operate the pump of a hydraulic elevator, superseding a motor of another make. The company is now filling orders for motors from four different elevator builders. These low speed machines are rapidly coming into favor for the operation of elevators, some being connected direct to the screw shaft of passenger elevators and some being belted to power elevators in the ordinary manner. They are giving great satisfaction under all these methods.

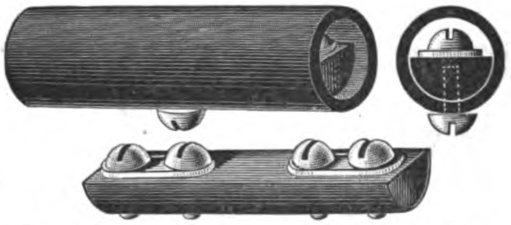
The motors are now equipped, unless otherwise ordered, with self-oiling bearings and with self-feeding carbon brushes, which require practically no attention or adjustment, thus avoiding all the difficulties with brushes sometimes experienced by those unfamilar with motors.

GREENBERG—CARNOTT.

Mr. A. G. Greenberg, special agent of the Fort Wayne Electric Co., was married to Miss Eleanor Gertrude Carnott, of Brooklyn, on December 17th, at the home of the bride's parents. After the ceremony the happy couple started South to enjoy their honeymoon. The many friends of Mr. Greenberg will be pleased to hear of his advent into the ranks of the Benedicts, and hundreds of well wishes will accompany the young people as they set sail on the matrimonial sea.

THE "MIDGET" COVERED FIXTURE CUT-OUT.

Among the recent productions of the Emerson Electric Mfg. Co., of 513 Elm street, St. Louis, Mo., is their "Midget" covered fixture cut-out, illustrated herewith, full size. This hard rubber cut-out is for electrolier and gas fixture work and to conform with the requirements of the fire underwriters. It is extremely small and compact. The cover is an important feature and will prevent much trouble from "grounds" in fixture work. The screw which holds the cover in place is tapped into both the cut-out and cover, and does not drop out and get lost, when loosened to remove the cover. It is substantially and well made, and while small size is the chief feature, the design provides for ample fusing break, long screw threads and sufficient room inside the cover for the wire.



The "Midget" Covered Fixture Cut-Out.

THE COMMERCIAL ELECTRIC COMPANY, OF DETROIT.

The Commercial Electric Company, of Detroit, Michigan, electrical engineers and contractors, have recently installed the following incandescent electric lighting plants: E. S. Fitch & Co., E. J. Hargraves & Son, Green & Bramen, Edmund Hall, Bousfield & Co., all of Bay City, Michigan; P. L. Sherman & Co., of Lidwood, Michigan; A. J. Douherty, of Clare, Michigan; Peninsular Car Co., of Detroit, Michigan, and are now fitting out the laboratory of Parke, Davis & Co. for 500 incandescent lights. Both their construction and supply departments are doing an excellent business and the prospects for business next year are very favorable.

THE "UNIVERSAL" ARC LAMP.

The "Universal" Arc Lamp Co., 49 West 22d street, this city, are meeting with considerable success in the introduction of their new style of arc lamp for incandescent circuits. These lamps are now on trial in the large Edison stations at Boston and Philadelphia. A number have also been sent to the station at Amsterdam, N. Y., where they are giving very good satisfaction. These lamps burn two in series on 100 and 110 volt circuits, and require but 9 amperes of current.

Mr. C. B. Hanna, the general agent of the Carpenter-Nevins Electric Heating Co., of Minneapolis, Minn., reports the equipment of seven cars with their well-known system of electric heating apparatus for the Tacoma and Steilycoomb Street Railway Co., of Tacoma, Wash.

QUEEN & CO.

Queen & Co., Philadelphia, have just finished "taking stock," and are congratulating themselves that in spite of the general dulness in business during the past three months their sales have been greater than ever before, and the demand for their specialties is increasing month by month.

Their standard resistance boxes, portable testing sets, ammeters and voltmeters, photometers, both portable and stationary, are of such a quality as to demand at least careful consideration, and large orders are received from all parts of the United States, as also for export.

In addition to manufacturing a full line of instruments of the regular types, they are continually engaged in designing new apparatus to meet the ever varied wants of the electrical engineer.

In this connection should be mentioned the new testing laboratory which Queen & Co. have added to their establishment. The room heretofore used for such purposes proving too small for the increasing work, a large isolated apartment has been built, which will contain everything necessary for first-class work.

Queen & Co.'s factory is one of the finest in America, devoted to the manufacture of scientific instruments. Skilled workmen are employed, and the lathes and other tools are the best and most complete. Close attention is given to the making of apparatus for special work after designs or specifications furnished, or they will design instruments to fulfill special requirements. With Prof. Anthony as consulting electrician in addition to the competent corps at their headquarters they are certainly well prepared to handle their large and increasing business.

MR. F. SARGENT, CHICAGO.

Mr. Frederick Sargent, the well-known mechanical and electrical engineer, Owing's Building, Chicago, has just been officially appointed electrical engineer-surveyor for the Western district, which comprises the great lakes of the United States Standard Steamship Owners', Builders' and Underwriters' Association. The selection of Mr. Sargent for this responsible position is a most timely one, as his reputation in electrical and engineering work is widespread all over the country.

He has had a most extensive experience in marine engineering. This is the only association that inspects under well framed rules electrical installations in vessels.

In land installation inspection has become a prime and indispensable factor of the greatest value to all concerned, and the same necessity for inspection exists on steamships. Those interested in marine installations should see to it that the work is carried out under the eye of a competent inspector, thereby ensuring thorough and proper workmanship.

Mr. Frederick Sargent has also just completed plans of the new South Side Edison station at 26th Street and Wabash avenue, and the whole plant will be built in accordance with the same and to the specifications of Mr. Sargent, who is consulting engineer of the company. He has also furnished plans and specifications for a new arc light plant for the People's Light & Power Co., of South Chicago.

ARMINGTON & SIMS ENGINE CO.

The *Providence Journal* in its admirable yearly review of local growth says: The Armington & Sims Engine Company report about the same story as told a year ago; a constant, steady increase of business. There has been no time during the past year when they have not had a very large number of orders booked, and the amount of business done shows an increase of fully 33 1-3 per cent. over 1889. As the demand increases they have gradually increased their plant and facilities, until they now have the largest and best equipped concern in the world for their especial line of work. They have a large amount of work in progress, not only for their standard high-speed engines, but also special engines of large sizes for electric power stations and large triple compound engines for rolling mills. The outlook for the coming year is favorable for a very large business."

A NOVEL FEATURE FROM THE NASSAU ELECTRIC CO.

A striking and novel electrical effect was produced at the Amphion Theatre, Brooklyn, on Tuesday of last week, in the play called "Jenny Daw," by the Hattie Harvey Company, in the shape of electric canes and umbrellas carried by the performers. Small incandescent lamps were placed in the handles of the canes and umbrellas and at a given signal they were flashed up, producing a weird and beautiful effect. These canes and umbrellas were manufactured expressly for this performance by the Nassau Electric Co., No. 19 Park Place, this city.

Gibbon Duplex Rails.—Arrangements have been made by the Gibbon Duplex Rail Co., of this city, with the Illinois Steel Co., of Chicago, to roll the Gibbon duplex rails for the West, and with the Tidewater Steel Co., of Chester, Pa., to roll those used in the East. By this arrangement a great saving is to be effected in the item of freight.

WESTERN TRADE NOTES.

Mr. George Cutter has returned from a highly successful business trip to the East and is now busily engaged preparing to meet a large demand for his many patented specialties. He is now fitting up a shop in the most complete and thorough manner in which these will be manufactured on an extensive scale, and he will soon place them on the market in very large quantities, together with the many new and good things which he has in store for '91.

The Electrical Supply Co, Chicago, have issued to their many patrons and friends a most beautiful souvenir for the new year. It consists of a handsomely printed card of eight pages, the prominent feature being a composite photograph of the ten gentlemen who are at the heads of the various departments, as follows: F. S. Terry, manager; Wm. Taylor, assistant manager and Electric Railway Department; Wells Goodhue, Electric Light and Power Department; W. R. Pinckard, House Goods Department; H. D. Ames, Accounting Department; Charles Wirt, Electric Light Engineering Department; M. M. Wood, Electric Railway Engineering Department; G. W. Conover, Purchasing Department; G. G. Carter, Sales Department; D. D. Merton, Advertising Department. That the Electrical Supply Company are artists in getting up attractive souvenirs and the like has long been an acknowledged fact by all who have perused their many and striking novelties in this line, but they have excelled themselves in their last unique effort. In a few fitting words of friendly greeting they introduce themselves in their unity as they appear to the great electrical fraternity.

The Illinois Electric Material Co. are kept busy filling orders for poles, "Canvas-jacket" and Bishop wire, and their other numerous specialties. They are placing a very efficient and economical incandescent lamp on the market.

The Electric Merchandise Co. are doing a brisk business in electric railway supplies of all kinds to which business they devote themselves exclusively. Inquiries for their new "mammoth catalogue" are numerous. It will contain an immense fund of the most useful information.

"**The Age of Steel**," published in St. Louis, an old technical journal of established merit and ever renewing enterprise, salutes the New Year with a most interesting issue largely devoted to the industrial growth and progress of the South. It is replete with valuable statistics, and as all the articles are by authorities, the opinions and deductions are entitled to unusual consideration.

NEW ENGLAND TRADE NOTES.

The National Pipe Bending Co., of New Haven, Conn., manufacturers of the well known National Feed Water Heater, have opened a branch office at 8 Oliver street, Boston, under the charge of Mr. T. P. Lennox. Among the most recent sales of Mr. Lennox in this territory, are a 600 h. p. heater to the Lowell Electric Light Corporation, Lowell, Mass., a 500 h. p. heater to the Edison Illuminating Company, of Newport, R. I., and a 200 h. p. heater to the Newburyport Street Railway Company, of Newburyport, Mass., for their new electric railroad.

The Standard Electric Company of Vermont have sold a 500 light plant to the Washington Market Company, Washington, D. C. The plant will be used for lighting the armory and the cold storage part of the market building.

The Germania Electric Co., of Marlboro', Mass., has been formed to go into the business of manufacturing incandescent lamps. Mr. George Fred. Williams is counsel for the company, and among its promoters are Messrs. H. B. Endicott and Winslow Warren, of Dedham.

Mr. H. F. Parshall, formerly general manager of the Wenstrom Electric Manufacturing Company, at Baltimore, has entered the service of the Thomson-Houston Electric Company, and will be stationed at Boston.

Messrs. S. C. Nightingale and Childs are extremely busy at present furnishing their magnesia covering for steam pipes in a large number of electric light and power stations throughout New England. Steam engine manufacturers also are using it in large quantities for covering the cylinders of their engines, and find it a most efficient preventative of radiation of heat.

ST. LOUIS TRADE NOTES.

Wr. A. W. Dutton, the Southwestern representative of the Brush Electric and the Short Electric Railway Companies, has closed a contract for an electric road at Texarkana, Ark., also a No. 4 steamboat plant for the new steamer "City of Sheffield," of the St. Louis and Tennessee River Packet Co.

The Emerson Electric Manufacturing Co. are now manufacturing the Bagnall trolley crossing, which has been adopted by the Lindell Railway Co.

Mr. H. P. Broughton, a Cornell University man of '90, has taken the agency for Chadbourne, Hazelton and Co., and The Consolidated Electric Storage Co.

THE
Electrical Engineer.

VOL. XI. JANUARY 21, 1891. No. 142.

THE INVENTORS OF THE ELECTRIC MOTOR.—III.

WITH SPECIAL REFERENCE TO THE WORK OF THOMAS DAVENPORT.

BY

Franklin Leonard Pope.

RANSOM COOK, the new partner in the enterprise, was in many respects no ordinary man. A native of Connecticut, he had been brought to the state of New York by his parents while yet a child, and had begun life in the then newly settled region of the upper Hudson as a journeyman cabinet-maker. Having by diligence and economy accumulated a small capital, he commenced on his own account in 1822, the manufacture of furniture in Saratoga Springs, and a few years later was able to fit up the large and well equipped shop referred to, which stood on the site of the present Grand Hotel.

Ransom Cook

AGED 83 YEARS AND 7 MONTHS.

[*From a Photograph made in 1877, by W. H. Baker, of Saratoga, N. Y.*]

Cook was a characteristic type of that self-educated, intelligent, ingenious, and enterprising class of American mechanics, the products of whose industrial skill have become known and esteemed in every country of the civilized world. From his very boyhood, every moment that could be spared from toil was utilized to the utmost in increasing the small store of knowledge with which a common school education had furnished him, and books, not only of the natural sciences, but of history, law and politics, were his unceasing recreation and delight. A man of scrupulous integrity, diligent and successful in business, cordially detesting every form of chicanery and hypocrisy, yet ever ready with hand and purse to aid the needy and deserving; distinguished no less for his sound judgment than for his self-reliance and independence, he was one who could not but occupy a leading position in any community in which his lot was cast. Touched with the narrative of Davenport's struggles and misfortunes, not only did Cook hasten to relieve his immediate pecuniary necessities, but instinctively perceiving the future possibilities of his invention, he suspended the lucrative business which he was carrying on, that he might throw himself heart and hand into the new enterprise. Writing of this period Davenport says :—

> My mind was now measurably relieved, and I felt that I could apply myself to the object in view, with renewed diligence. As the patent had not been obtained, we commenced building a model for the Patent Office. Mr. Cook seemed to be more and more enamored with the invention as the work progressed. Several hands were now employed in constructing models, and important alterations in the arrangement of the machine were made by Mr. Cook, which seemed to increase his confidence in the ultimate successful application of the power. As soon as we had completed a model for the Patent Office, I proceeded to Washington and deposited my model and papers. A great variety of experiments were made in Mr. Cook's shop, with regard to the best mode of constructing both steel and electro-magnets, and many models of various sizes were completed.

At least two of the working models constructed by Davenport and Cook during the winter of 1836-7 are fortunately still in existence in an excellent state of preservation. The writer has had an opportunity of making a careful examination of one of these, a small electric locomotive running on a circular railway 24 inches in diameter, an illustration of which is given herewith. The motor proper consists of two straight electro-magnets, one constituting a stationary field, and the other an armature revolving in a horizontal plane parallel to and above the field. The armature is connected with the driving wheels by a speed-reducing bevel-gear. The field and armature magnets are each 5½ in. long, with cores ¾ in. in diameter. They are each wound with two No. 16 copper wires connected in parallel, there being 24 convolutions of each wire on each core. The commutator is constructed with insulated springs rubbing upon insulated metallic segments. The connections with the battery are formed by mercury-cups. Perhaps the most remarkable circumstance about this motor is that the field and armature are connected in parallel, so that in this model we have a veritable example of a *shunt-wound motor*, built in 1836-7. The workmanship of the little machine is of the finest description, and would reflect no discredit upon the shop of any leading manufacturer of to-day. It bears in every feature the impress of the unusual mechanical skill of its designer. This model of the circular railway, together with several stationary motors embodying the same general principles, were intended for exhibition in the city of New York. Near the close of the year 1836, Davenport, who was impatiently awaiting the issue of his patent, received a letter from Congressman Slade, conveying the unwelcome intelligence that his model and all the papers relating to his application had been destroyed in the fire which consumed the contents of the patent office. Not a paper nor a single one of the 7,000 models contained in the hall escaped destruction.

This disaster occurred on the 15th of December, 1836. Another model was immediately constructed and a new set of papers prepared, and about the middle of January, 1837, Davenport, supplied with funds by Cook, set out on his third journey to Washington, and filed an application on January 24, 1837, for his patent, which was issued in due course on the 25th of February following.

The following extract from the columns of a local journal will serve to show the stage which the invention had now reached :

> [*From the Saratoga Sentinel*, *Jan.* 3, 1837.]
>
> DAVENPORT AND COOK'S ELECTRO-MAGNETIC ENGINE.
>
> In company with Dr. Steel and several other gentlemen, we called upon Messrs. Davenport and Cook, of this village, on Saturday, with a view of examining the electro-magnetic engine invented by the senior partner.
>
> The ingenuity, yet simplicity of its construction, the rapidity of its motion, together with the grandeur of the thought that we are witnessing the operation of machinery propelled by that subtle and all pervading principle—electricity, combine to render it the most interesting exhibition we have ever witnessed.
>
> Although we shall say something on the subject, it is perhaps impossible to describe this machine by words alone, so as to give more than a faint idea of it to the reader.
>
> It consists of a stationary magnetic circle, formed of disconnected segments. These segments are permanently charged magnets, the repelling poles of which are placed contiguous to each other. Within the circle stands the motive wheel, having the projecting galvanic magnets, which revolve as near the circle as they can be brought without actual contact. The galvanic magnets are charged by a battery, and when so charged, magnetic attraction and repulsion are brought into requisition in giving motion to the wheel—the poles of the galvanic magnets being charged more than a thousand times per minute. . . .
>
> We were shown a model in which the motive wheel was 5½ inches diameter, which elevated a weight of twelve pounds. And to [illegible] the facilities for increasing the power of this engine, another model was exhibited to us with a motive wheel of eleven inches in diameter, which elevated a weight of eighty-eight pounds. Although these models have been for some time in progress, and we have occasionally been permitted to examine them, we have waited till the present period, when the practicability of obtaining a rapid and unlimited increase of power seems to be placed beyond a doubt, before expressing an opinion, or calling the public attention to the subject.
>
> If this engine answers the expectations of the inventor (and we believe no one can assign a reason why it should not), it is destined to produce the greatest revolution in the commercial and mechanical interests which the world has ever witnessed.

While Davenport was in Washington attending to the issue of his patent, Cook formed in New York the acquaintance of a typical representative of a class of people who have become in later years much more widely than favorably known in electrical circles as "promoters." This person, whose prominent position as secretary of one of the leading scientific and technical institutions in New York apparently entitled him to confidence, suggested the advisability of forming a joint-stock association to exploit the patent. To this Cook, and Davenport, after his return from Washington, willingly acceded, the more so, that they had found that the cost of procuring patents in the different countries of Europe, and of building a machine large enough to give the public convincing proof of the value of the discovery, would be likely to be considerably beyond their individual resources. In accordance with this plan, early in March articles of association were drawn up, by the terms of which a portion of the stock was placed in the hands of the promoter to enable him to raise funds "for building models and machinery, and for testing the utility of said invention; for giving to the same its greatest possible value for the benefit of the stockholders (the constructions so made to belong to the association); also for securing the exclusive use of said invention in Europe for the benefit of the association."

A supplementary agreement was executed at the same time, by which the promoter pledged himself to pay Davenport and Cook $12,000 in cash within thirty days. This was a large sum of money in those days, and the struggling inventor at last felt able to congratulate himself that his pecuniary troubles at least were at an end.

Every prospect seemed as favorable as could be desired or hoped for. As a curiosity we give a fac-simile of one the certificates of scrip of this—perhaps the first joint stock company ever organized to exploit an electrical invention.

In March, Davenport received a letter from Professor Benjamin Silliman, of New Haven, requesting information about his machine for publication in the *American Journal of Science* and adding:

> I have no doubt you will always receive advantage from the sound and judicious advice of our friend Mr.——— (the promotor) whose experience in business and great zeal and fidelity in this affair will no doubt greatly aid in all the proper business part of your concern.

The publication in Silliman's Journal of April, 1837, of a detailed description from personal examination of two different forms of Davenport's machine, one having revolving electro-magnets in conjunction with fixed permanent field magnets, and the other composed entirely of electro-magnets both in its fixed and revolving members, excited very great interest in scientific circles both in this country and abroad. At the end of the article, which is signed with the initials of Professor Silliman, the author sums up his conclusions in reference to the invention as follows :

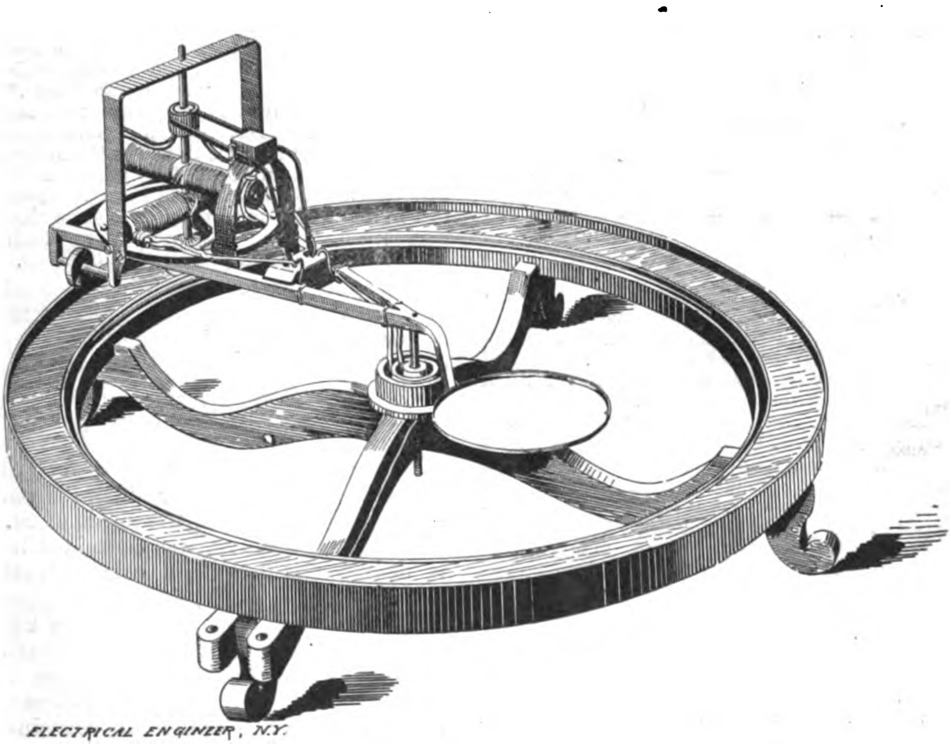
> 1. It appears then, from the facts stated above, that electro-magnetism is quite adequate to the generation of rotary motion.
>
> 2. That it is not necessary to employ permanent magnets in any part of the construction, and that electro-magnets are far preferable, not only for the moving, but for the stationary parts of the machine.
>
> 3. That the power generated by electro-magnetism may be indefinitely prolonged, since, for exhausted acids and corroded metals, fresh acids and batteries, kept always in readiness, may be substituted, even without stopping the movement.
>
> 4. That the power may be increased beyond any limit hitherto attained, and probably beyond any which can be with certainty assigned—since, by increasing all the members of the apparatus, due reference being had to the relative proportionate weight, size, and form of the fixed and movable parts—to the length of the insulated wires and the manner of winding them—and to the proper size and construction of the battery, as well as to the nature and strength of the acid or other exciting agent, and the manner of connecting the battery with the machine, it would appear certain, that the power must be increased in some ratio which experience must ascertain.
>
> 5. As electro-magnetism has been experimentally proved to be sufficient to raise and sustain several thousands of pounds, no reason can be discovered why—when the acting surfaces are, by skillful mechanism, brought as near as possible, without contact—the continued exertion of the power should not generate a continued rotary movement, of a degree of energy, inferior indeed to that exerted in actual contact, but still nearly appoximating to it.
>
> 6. As the power can be generated cheaply and certainly—as it can be continued indefinitely—as it has been very greatly increased by very simple means—as we have no knowledge of its limit, and may therefore presume on an indefinite augmentation of its energy, it is much to be desired, that the investigation should be prosecuted with zeal, aided by correct scientific knowledge, by mechanical skill, and by ample funds. It may therefore be reasonably hoped, that science and art, the handmaids of discovery, will both receive from this interesting research a liberal reward.
>
> Science has thus, most unexpectedly, placed in our hands a new power of great but unknown energy.
>
> It does not evoke the winds from their caverns; nor give wings to water by the urgency of heat; nor drive to exhaustion muscular power of animals; nor operate by complicated mechanism; nor accumulate hydraulic force by daming the vexed torrents; nor summon any other form of gravitating force; but, by the simplest means—the mere contact of metallic surfaces of small extent, with feeble chemical agents, a power everywhere diffused through nature, but generally concealed from our senses—is mysteriously evolved, and by circulation in insulated wires it is still more mysteriously augmented, a thousand and a thousand fold, until it breaks forth with incredible energy; there is no appreciable interval between its first evolution and its full maturity, and the infant starts up a giant.
>
> Nothing since the discovery of gravitation and of the structure of the celestial systems, is so wonderful as the power evolved by galvanism; whether we contemplate it in the muscular convulsions of animals, the chemical decompositions, the solar brightness of the galvanic light, the dissipating consuming heat,

and more than all, in the magnetic energy, which leaves far behind all previous artificial accumulations of this power, and reveals, as there is full reason to believe, the grand secret of terrestrial magnetism itself.

We shall hereafter give an accurate drawing, made to scale, of one of three or four machines, substantially alike, which were constructed in the winter of 1836-37, by Davenport and Cook. The model in the patent office in Washington was one of these, another was sent to Europe to be used in obtaining patents in various countries, and at least one other was kept on exhibition in New York, where it was inspected by crowds of curious spectators.

The workshop and laboratory of Davenport and Cook were in a large building at 42 Stanton street, which has long since disappeared and been replaced by tenement houses. Writing of this period, Davenport says:

> During the spring and summer of 1837, our laboratory, which was a spacious one, was crowded to overflowing daily by visitors to examine the variety of machines and apparatus which were on hand, and in progress of construction. Among the distinguished and scientific gentlemen who visited our work, were Professor Samuel F. B. Morse, then of the New York University, and Doctor Charles G. Page, then of Boston. Professor Morse frequently mentioned his intentions of experimenting on the electro-magnet for the purpose of producing signs for signals for telegraphic purposes, and stated that he had long ago conceived the idea of transmitting intelligence by electricity.[1] A gentleman from Germany, Baron D——, purchased secretly from one of our workmen drawings of some of the best models, and in about six months from that time the German papers were teeming with the news that Baron D—— had invented a new motive power, a model of a machine, put in motion by electro-magnetism! The German Diet is said to have voted this *gentleman pirate* 200,000 francs, or $40,000, as a compensation for his wonderful invention.[2] In the course of this summer we constructed a great variety of machines, testing the power of each to ascertain the amount of improvement, and among these was a miniature locomotive engine which moved on a circular railway of 14 feet in diameter, moving a train of half-a-dozen cars. Many of the public prints came out in favor of the invention, recommending that capitalists should examine the operation of the machines, and aid in the enterprise by their assistance in furnishing funds.



ELECTRICAL ENGINEER, N.Y.

MODEL OF ELECTRIC CIRCULAR RAILWAY MADE BY DAVENPORT AND COOK IN 1836-7.

[*From recent photograph and sketch by F. L. Pope.*]

Many of these newspaper notices are so characteristic, that I cannot forbear making a few extracts from them:

(*From the New York Herald, April* 27, 1837.)

A REVOLUTION IN PHILOSOPHY.—DAWN OF A NEW CIVILIZATION.

> We mentioned slightly the other day a few particulars descriptive of the electro-magnetic machine now preparing for exhibition in this city. We shall now go a little deeper into this most extraordinary discovery, probably the greatest of ancient and modern times, the greatest the world has ever seen, the greatest the world will ever see. . . . .
>
> We are in the commencement of a revolution in philosophy, science, art, and civilization. The occult and mysterious principle of galvanism is now beginning to be developed in all its magnificence and energy. . . . .
>
> It is utterly impossible to give vent to all those burning thoughts which crowd upon our mind at the contemplation of this discovery. It surpasses any discovery of ancient or modern times. The generalization of this principle, and its undoubted identification with all the phenomena of nature—with motion—with animal life—with earthquakes—with gravity—with electricity—with the motion of the earth and planets round the sun, must and will create an entire revolution in all science, in all art, in all philosophy, and in all future civilization. Indeed we may go further, and however droll it may appear, we have strong suspicions that the friendship, esteem and the mysterious love between the sexes is founded on the same principle with which Mr. Davenport turns his wheel, and the lightning flashes from heaven—and the aurora borealis spreads out its garments of rosy light in the sky—and the very planets themselves run their races round the sun from eternity to eternity.
>
> Enough for the present. We have long been a student in chemistry, electricity, galvanism, and such like sciences. We shall illustrate our views at our leisure. Meantime we bid all prepare for an organic revolution in science, philosophy, religion, and civilization. We are just entering upon a wonderful age.

(*From the N. Y. Evening Star, August*, 1837.)

> In concurrence, unanimously we believe, with all who have

---

[1] From the sworn deposition of Professor Leonard D. Gale, corroborated by others, printed in the record of the Supreme Court in the case of *O'Reilly* v. *Morse*, it appears that the first crude model of Morse's telegraphic recording apparatus was constructed by him in the late fall of 1835, and that Gale became associated with him in 1836. In his deposition Gale says:—"From April to September, 1837, Professor Morse and myself were engaged together in the work of *preparing magnets*, winding wire, constructing batteries, etc., in the University, for an experiment on a larger but still very limited scale, in the little leisure that each had to spare. . . . The latter part of August, 1837, the operation of the instrument was shown to numerous visitors to the University." It must have been while this work was going on, that Morse visited Davenport's laboratory. The marked likeness between the electro-magnet in the original instrument of Morse, preserved in the cabinet of the Western Union Telegraph Company, at 195 Broadway, New York, and the magnets in some of the motors of Davenport and Cook, constructed just before they brought their apparatus to New York, furnishes grounds for the belief that Morse's knowledge of the construction of Henry's magnet may, in part at least, have been derived from observations made during his visit to the laboratory here referred to.

[2] The writer, notwithstanding much research, has failed in his attempts to penetrate the incognito of the "gentleman pirate." The statement is given as it is written. Possibly others may be more successful.

witnessed the operations of this extraordinary and simple apparatus, and listened to the lucid and eloquent explanations of Mr. Cook, we confess our utter amazement at the prodigious changes which it manifestly foretells in the application of an entire new and immeasurable agent of mechanical power; and at the same time, while we see and admire, acknowledge ourselves, for want of language to sustain us, utterly incompetent to impart any correct conception of this marvelous invention to our readers. All we say is, "go and be convinced." . . . . . .

It is a sublime but not wild idea of Mr. Cook, that a ship's bottom, covered with suitable plates and the ocean for its bath, may drive herself along with incredible velocity, at the same time generating abundance of hydrogen to light her onward upon the deep. . . . .

But it is in a commercial view that it exhibits, in prospective at least, an importance combined with the finest sublimity. It is well known that sea-water forms an active bath for the galvanic battery when kept up by frequent changes. Is there any insurmountable objection to arranging the sheathing of the vessel so as to form a battery, and with the ocean for its bath and the application of magnetic power, "drive the ship onward in her course and guide her to the point of destination by the same agent?"

When the use of steam is proposed in conducting our distant commerce, we cannot avoid the reflection that on the vast deep the perils of wind and waves are sufficient without adding those of fire and explosion.

(*From the N. Y. Evening Post.*)

We learn that some recent improvements have been made in the application of electricity as a moving power to machinery. A larger apparatus than the one hitherto exhibited has been constructed under the direction of Mr. Cook, now in this city, which is to set in motion a turning lathe, in order that those who take an interest in the invention may see it at work. Nothing but the difficulty of the times now stands in the way of demonstrating the application of this power on a large scale to machinery of the most ponderous description.

(*From American Correspondence of London Morning Herald.*)

I did not write by the packet of the 16th [August, 1837], because I had made an appointment for the next day, to go and see the electric-magnetic machines of Mr. Davenport, and which I considered well worthy to be the subject of a letter, provided there were any grounds for the vast expectations founded upon them, not only by the inventor and his friends, but by every person who had examined them, and heard the explanations of Mr. Davenport. Having seen them, I am free to confess that I cannot discover any good reason why the power may not be obtained and employed in sufficient abundance for any machinery; why it should not supersede steam, to which it is infinitely preferable on the score of expense, safety, and simplicity. I do not very clearly understand the principle (something about changing the poles from positive to negative, or from north to south), and vice-versa, in rapid succession; but this is of little consequence, as I shall be able to send you, probably by the next packet, a pamphlet containing a full exposition, with illustrative engravings. Mr. Cook, who is associated with Mr. Davenport in the patent, is now engaged in preparing this pamphlet, and he has promised me the first copy that is printed. They have patented their invention in France and England. . . . .

The last machine constructed by Mr. Davenport occupies a surface of about 18 inches square, that is, 18 inches on each side, and consists merely of a platform, having upon it an iron circular frame, with an arch extending from side to side above it, a spindle in the centre playing in this arch at top and in a socket below, and on this spindle an incomplete wheel, formed of two cross pieces of iron, with segments of a circle at the four extremities. It is, in fact, a wheel, with four breaks in its periphery. Some hundreds of feet of isolated, or coated, copper wire are wound around the cross pieces, and also around the fixed circular frame; the connection with the galvanic batteries, which are three small cylinders, each consisting of six concentric tubes of zinc and copper, the outer one scarcely larger than a quart pot, is, formed by small rods of copper. The revolving wheel is six inches in diameter, and weighs about six pounds. Attached to the upright spindle is a small cog-wheel, which may be made to work in other wheels, with axles, for the purpose of showing how great a weight can be raised from the ground.

With the three batteries acting on it, the revolution of the wheel was 1,000 times in a minute; and these 1,000 revolutions raised a weight of 200 lbs. one foot. The first machine made by Mr. Davenport, which is much smaller and has but one battery, raised but 24 lbs. He is confident that with a number of batteries, or one very large one, say, as big as a barrel, there would be power enough to drive the largest machinery, while the cost of construction would be reduced to a fifth, or perhaps a tenth, and that of attendance, fuel, etc., now forming so heavy an item in the expenses of steam-power, would be almost done away with. Half a barrel of blue vitriol, and a hogshead or two of water, would send a ship from New York to Liverpool; and no accident could possibly happen, beyond the breaking of some part of the machinery, which is so simple, that any damage could be repaired in half a day. Surely it is a great and vastly important discovery, and the wildest imagination could hardly grasp the wonders in achieving which it may, and doubtless will, become the instrument.

A reference to the preceding description of the machine shown to the correspondent of the London *Herald*, is sufficient to show that it was quite an advanced type of motor, having a horseshoe field, and a four-pole armature fitted with segmental polar surfaces. A model of one of the machines of this type, but having two poles only, is still in existence.

Amid the general chorus of praise, there was, as might have been expected, now and then an inharmonious note, as witness the following communication:—

[*From the Journal of Commerce.*]

Messrs. Editors: I have been much gratified with your exposure of various humbugs of late in science and politics; but if I recollect right, you have not touched upon what I consider as also indubitably a great humbug. I mean Mr. Davenport's machine, so far as it boasts of being of any practical utility. I am aware that Mr. Silliman speaks of Mr. Davenport's invention as "putting into our hands a new power of great but unknown energy," and supposes the power may be increased beyond any limit which can be assigned; he therefore seems to speak of the discovery as of great pecuniary value, and recommends that the investigation should be prosecuted "by ample funds," etc. Mr. S. has not, however, shown in what way any great and useful power is to be attained by Mr. Davenport's invention, and probably he would not again lend his name in the same manner to this affair. I am aware also that Mr. D. is able by his machine to move a couple of tiny cars about a railroad in Barclay street, of a dozen or fifteen feet in diameter; but I propose to show that he cannot, by electro-magnetism, acquire any great and valuable power, and that his machine in its grand promise is a *humbug*.

Annoying caricatures were also circulated, a fashion much in vogue at that day. One of these skits represented a boat propelled by lightning; Davenport and Cook, with despair depicted upon their countenances were tinkering at the machinery, while Prof. Silliman, in an attitude of mock dignity, was expatiating to the public on the merits of the scheme.

So far as can be ascertained, the earliest account of the experiments of Professor Moritz Hermann von Jacobi, of Königsberg, Prussia, afterwards of St. Petersburg, which reached this country, was contained in a paper published in Sturgeon's *Annals*, translated from *Comptes Rendus.*[3] This admirable paper, which, considering the early date of its publication, displays a masterly knowledge of the fundamental principles of electro-magnetism, as well as an intimate experimental acquaintance with its phenomena, especially as exhibited in the actions and reactions of the magnets of an electric motor, contains a full description of Jacobi's machine, illustrated with an isometrical drawing which clearly exhibits the details of its construction. From this drawing, which we reproduce in fac-simile, it clearly appears that not only is its principle the same as that of Davenport and Smalley's motor heretofore described, but that even in the details of construction the differences are comparatively unimportant. In this paper, Jacobi states that he first succeeded in obtaining rotary motion in May, 1834, and incidentally refers to a paper partially describing it, which he read before the Academy of Sciences of Paris, on December 1, of the same year, an abstract of which was published in *l'Institut*, No. 82, on December 3rd. The following is a translation of this note:—

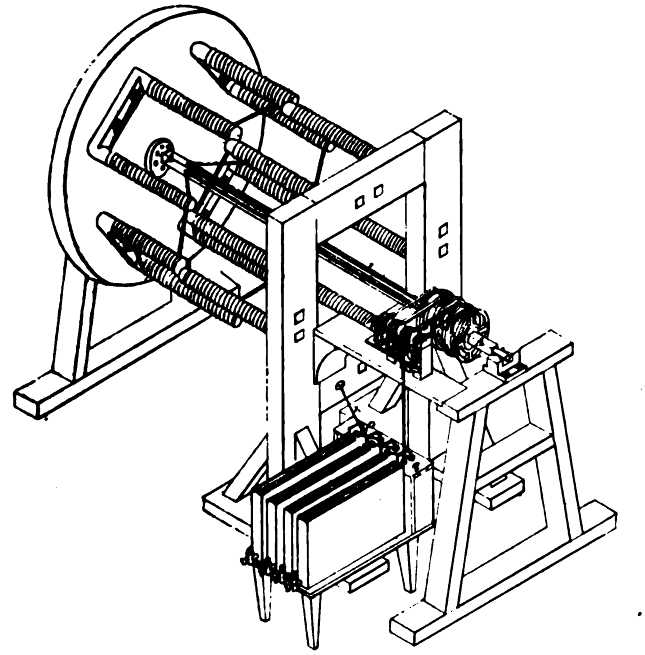
M. Jacobi, of Königsberg, presented to the Academy a paper on a magnetic engine of his invention, in which magnetism is employed as a motive power. The following is the description given of it:—The apparatus consists of two systems comprising eight bars each of soft iron, each 7 in. long and 1 in. in diameter. These two systems of bars are placed at right angles, and so arranged on two discs that the ends or poles of the bars are opposite one another. One disc is fixed while the other revolves on its axis, and the movable bars are thus made to pass as close as possible in front of the fixed ones. The 16 bars are wound with 320 feet of copper wire, ¼ inch in diameter, the ends of which were connected with a voltaic apparatus. The whole mass, moving at a speed of six feet per second, gives about 50 lbs., being a considerable *vis viva.* The work thus furnished, measured by an apparatus similar to the Prony brake, is equal to a weight of 10 or 12 lbs. lifted one foot per second. This success is principally due to a novel construction of the commutator by which the changes of polarity are worked. These take place eight times in each complete revolution; that is to say, eight times in half or three-quarters of a second, the ordinary speed of the machine, when the water in the cell is so little acidulated that the development of gas is hardly appreciable.

---

[3] Sturgeon's *Annals of Electricity*, etc., i., 408.

In 1838, under the patronage and at the expense of the Emperor Nicholas, of Russia, Jacobi constructed a much larger motor upon substantially the same principles, with which he succeeded in propelling a boat upon the Neva, at St. Petersburg. As full accounts of this experiment have been many times published, I will not occupy space by repeating them here. The illustration given will suffice to show the general character of the motor used on this occasion.

The question of actual priority, in point of time, as between the invention of Davenport and that of Jacobi is a very close one. If the rotary motion which Jacobi obtained in May, 1834, was effected by the identical apparatus described in his paper read before the Academy in November of that year, then his priority must be conceded, but it does not appear to be certain that such is the case. In any event, the discoveries here and abroad must necessarily have been wholly independent, although nearly coincident in point of time, and it is, to say the least, remarkable, that one who labored under such limitations and disadvantages as Davenport, should by the unaided force of his native genius, have achieved a result which has been universally conceded to reflect the highest credit upon the talents and perseverance of one of the most able and learned experimental philosophers of his day.



JACOBI'S ELECTRO-MAGNETIC ENGINE OF 1834.

[*Reproduced from Sturgeon's Annals.*]

The following letter, written near the close of the year 1837, gives an interesting résumé of the progress of affairs in the laboratory at that date[4]:

[*Thomas Davenport to Professor Benjamin Silliman.*]

Dear Sir:—Having lately made a number of applications of the power of large galvanic magnets in propelling machinery (being independent of the large machine now constructing by the association*), I have thought proper to state to you the results, believing they would not be uninteresting to you.

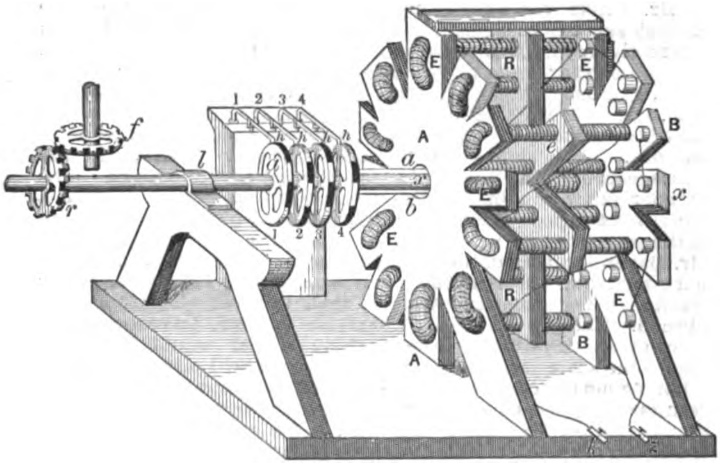
I have constructed a machine with two revolving magnets 2 feet in length, made of iron, 3½ inches in diameter, and weighing, after being wound with 6 coils of No. 10 copper wire, 100 pounds each. Three stationary magnets of 2 feet diameter, were placed around the periphery, making 6 poles and weighing 100 pounds each.

With this machine I have produced 100 revolutions per minute with 6 square feet of sheet zinc exposed to action, surrounded with thin sheet copper.

I then displaced the stationary magnets, and substituted one magnet 8 inches in diameter, forming a semi-circle, with the poles directly opposite each other, and weighing about 100 pounds. With this magnet I produced 150 revolutions per minute, using the same quantity of zinc surface. With one revolving magnet I produced 175 revolutions per minute, with 4 square feet of sheet zinc. I next constructed a hollow magnet 2 feet in length and 4 inches in diameter, made of boiler iron, 5/16 of an inch in thickness, with 4 coils of copper wire, with which I succeeded in getting 100 revolutions per minute. A hollow magnet was then constructed of thin sheet-iron, of the thickness of common stove-pipe iron. which revolved 150 times per minute. Hollow magnets I think may be used to great advantage where weight is an objection; but in my experiments I generally make use of solid iron.

I also constructed a machine with simply two magnets formed of 2-inch round iron, 15 inches in length, of the stirrup form. The distance between the centres of the poles is 5 inches and the magnet revolves 450 times per minute, with 2 square feet of zinc. The stationary magnets being placed with the poles of the revolving magnet pointing downwards, the shaft to which the revolving magnet is attached passes through its centre and rests on the centre of the stationary magnet. Two of these machines (weighing in all 50 pounds) I have attached to small drilling works, which I find produce sufficient power to do all my drilling of iron and steel, to the size of ¼ of an inch in diameter.

I have adopted this form on the third machine which I have recently put in operation. The magnets are formed of 2¾ inch iron, with the centres of their poles 9 inches apart and weighing 50 pounds each; with this I produced 300 revolutions per minute, and have successfully applied it to turning hard wood of 3 inches diameter. I find the power increases in full proportion to the increase of weight and without increasing in proportion the size of the battery. The wire must be increased in size in proportion to the size of the iron used, and, consequently, the difficulty attending long wires will always be avoided.



MOTOR USED BY JACOBI IN HIS EXPERIMENT ON THE NEVA IN 1838.

[*By permission of D. Van Nostrand Co.*]

I find no difficulty in using my machine 12 hours in succession, without changing batteries or agitating the solution.

I am erecting conveniences to test the powers of each magnet as they are increased in weight and size, and think I shall be able in season for the April number of your journal to give the exact increase of power in proportion to weight, of magnets weighing from 10 pounds to several tons.

I have also made some very satisfactory trials, while making my machines, respecting the expense for the consumption of zinc and acids, and I think I shall soon be able to give nearly the precise cost of making the largest machinery.

Galvanism is, I trust, destined to produce the greatest results in the most simple form, and I hope not to be considered an enthusiast, when I venture to predict, that soon engines capable of propelling the largest machinery will be produced by the simple action of two galvanic magnets, and worked with much less expense than steam. Yours respectfully,

New York, Dec. 26, 1837. THOMAS DAVENPORT.

---

[4] Silliman's *Amer. Jour. Sci.*, xxxiii. (appendix).

* The machine alluded to in the above letter, as now being constructed for the Electro-Magnetic Association, by Messrs. Davenport and Cook, is nearly completed, and is expected to be of about two tons' power. It is formed by a combination of small magnets, weighing about four pounds each, and three-and-a-half inches between the poles. These magnets are placed—two hundred and thirty-four in number, on an iron shaft six feet in length, and a corresponding number in a circle as stationary magnets.

In 1838, Frederic Coombs was sent abroad to obtain patents in Great Britain and other countries, and to exhibit the invention with the hope of enlisting foreign capital in aid of the enterprise. The following notice was published in the proceedings of the London Electrical Society, of its meeting of July 17, 1838:[5]

> Previous to the chair being taken, Mr. Coombs, of New York, exhibited to the members a locomotive engine propelled by electro-magnetism. This machine, which is at present exhibiting at the Royal Gallery of Practical Science, consist: 1st. Of the carriage containing the apparatus, but which, in consequence of the arrangements necessary to the taking out of a patent in this country not being completed, could not be explained. 2d. Two voltaic batteries; these are made on the principle of Hare's calorimotor, excited with a strong solution of sulphate of copper. 3d. Two carriages attached to the apparatus. The apparatus, batteries, and carriages weigh 60 or 70 lbs., and are placed on a circular railroad. Upon connexion of the apparatus being completed (by means of four cups containing mercury) with the poles of the two batteries, the apparatus is set in motion and revolves for some time with considerable velocity, but which decreases as the action of the battery diminishes.

The exhibition appears to have been favorably received by the members present, but it does not appear that anything further was accomplished. The following is selected from a number of newspaper notices:

[*From the London Morning Herald, August*, 1838.]

DAVENPORT'S ELECTRO-MAGNETIC RAILWAY LOCOMOTIVE.

> Mr. Davenport has at length gratified the curiosity of the English skeptics to a certain extent, by sending over a model of a locomotive engine, which is now exhibiting at the Adelaide Gallery, in the Lowther Arcade, worked on the same principle as his larger stationary engines. This carriage runs on a circular railway, and draws after it two other carriages, which move, by the aid of two small galvanic batteries, at the rate of about three miles an hour. The weight thus propelled is nearly 80 lbs., and the carriage containing the apparatus about one foot square. The manner in which the electro-magnets are arranged is kept a secret for the present; but the principle on which the application of the power depends is well known, and the chief superiority in Mr. Davenport's invention consists in his having, by some peculiar contrivance, brought into exercise a greater amount of power within a given space and weight, than has been hitherto accomplished. Though we do not anticipate that Mr. Davenport's invention as exhibited in the working model would be found applicable on a large scale with any practical advantage; yet what he has accomplished is sufficient to show that important results may be expected from future improvements in the application of the same principle. We are informed by an American gentleman who has recently arrived in England that he witnessed a two horse power electro-magnetic engine, of Mr. Davenport's construction, employed in printing a newspaper in New York, and that it performed the work most satisfactorily. Whether or not, however, this was done at a cheaper rate than the same power might be obtained from steam, we are not able to ascertain.

Frederic Coombs, the exhibitor of the Davenport motor in England, in his old age became mentally unbalanced, and from his harmless eccentricities of dress and behavior was, for many years, a well known character in the streets of Washington, San Francisco and New York. His personal appearance was remarkable, combining as it were, the stately dignity of a Washington with the affable and condescending benevolence of a Franklin. The portrait given herewith will be recognized by many of our older readers.

The peculiar business methods pursued by the individual who had been entrusted with the management of the financial interests of the association soon came to be of a character to excite the suspicions both of his associates and of the public. His plan appears to have been a sufficiently simple one, namely, to sell shares to any one who could be induced to purchase, at any price the party could be induced to pay, and to put the proceeds in his own pocket, at the same time persistently refusing to render to his associates any account of his doings, but reluctantly disgorging, from time to time, such sums of money as were absolutely necessary to keep the laboratory going with the smallest possible number of employés. This course of conduct could have but one result. The confidence of the public generally in the integrity of the management of the association became impaired, while those who had purchased shares not unnaturally began to entertain suspicions that they had been duped. Ransom Cook was a man who was not only peculiarly sensitive in matters of honor, but one who was utterly without patience with fraud or chicanery in any form. He did not hesitate to express his disappointment and vexation at the conduct of the business manager, and ultimately, on the 12th of February, 1838, he sold nearly the whole of his interest for a mere pittance, withdrew in disgust from the enterprise, and returned to his home in Saratoga. During the year they had carried on operations in New York, Cook had expended on the work some $3,000, and Davenport more than $2,000 of their own money, while the total amount received from their business manager, instead of the promised $12,000, was only $1,700. After the departure of Cook, Davenport and M. W. Nelson, the party who had purchased Cook's interest, brought a suit in chancery against their unprincipled associate, the result of which was that the court compelled the latter, much against his will, to exhibit his books and render an account of his stewardship. Davenport had meantime sold a part of the patent right for the New England States which he had reserved to himself, and the proceeds furnished him with means to continue his experiments for a time without other aid.

One cannot but deplore the unfortunate occurrences which led to the permanent withdrawal of such a man as Ransom Cook from further association with a department of experimental research, in which his natural tastes, no less than his remarkable talents, so eminently qualified him to achieve distinction. An artificer of surpassing skill; a diligent and observant student of nature's ways and works; an original thinker, and an inventor of a high order; the brief story of a single one of Cook's mechanical conceptions will portray more vividly than volumes of description the rare genius of the man. Ever full of intelligent curiosity regarding the cunning works of nature, he became at one time absorbed in the study of the structure and habits of the so-called "ship-worm" (*teredo navalis*). More than anything else, he was struck with the capacity of this little creature to apply its cutting tool with equal facility and efficacy, at any angle to the grain of the wood, and as a skilled wood-wooker, his mind at once seized upon and sought to apply the hint which nature had thus given. Patiently and skillfully, with his own hands, he forged from steel experimental augers and bits, with cutters modeled from the teredo's mandibles, until at last the result was achieved; the curved tips of the justly celebrated "Cook bit," an implement which by sheer intrinsic merit has made itself indispensable to the "kit" of every woodworker in the civilized world. Of his many other scarcely less ingenious and original conceptions, space forbids even a passing notice here. In the autumn of his days, retiring with a handsome and well-earned competency from the active pursuits of life, he provided himself with a well-stocked library, and a model laboratory equipped with the most improved mechanical appliances and scientific apparatus. Here it was his especial delight to entertain his chosen friends, among whom were numbered many of the most prominent of public men and scientists who were his contemporaries. He died at Saratoga Springs, N. Y., May 26, 1881, at the advanced age of 87. It is impossible to resist the conviction, that had Ransom Cook continued to devote his unusual and peculiar talents to the industrial development of electro-magnetism, many of those knotty problems, which for so many years confronted and obstructed the pathway of the investigator, would have received at his hands an earlier solution.

Thrown once more upon his own resources, Davenport proceeded to build several larger machines, of a type very similar to that of the model locomotive in the illustration on page 67, referring to which he says:

---

[5] Sturgeon's *Annals of Electricity*, etc., iii. 156.

I increased the size of my magnets to about 50 lbs. each, and with four machines, with two of these magnets in each, I moved a large Napier printing press in the month of April, 1838. There was not, however, sufficient power for printing papers, although the machine would keep the press in motion.

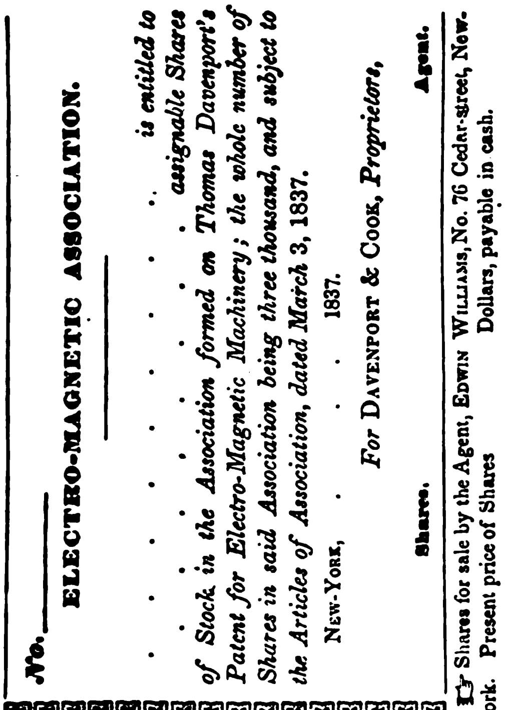
While engaged in these experiments, he received a letter from Dr. Charles G. Page, then of Boston, who had been for some time engaged in exploring the same field. It is of interest as showing the views of Page at that date, and especially in view of the reference to the experiment of arresting the rotation of a magnetic bar by what is obviously an inductive action:

[*Charles G. Page to Thomas Davenport.*]

BOSTON, April 28th, 1838.

THOMAS DAVENPORT, ESQ.,

Sir:—I have for a long time (as is well known to you) been pursuing the same experiment as yourself, but for many months past, I believe I have been on an entirely new and different track. My main object has been to prevent retardation or back action. My plan is to cut off the galvanic current from both systems of magnets instead of changing poles as they arrive at equilibrium. The advantage of this I have fully tested, and my model for a patent went to the office three months ago. I have had notice from the Commissioner that it should be attended to as soon as practicable, but the certificate has not yet arrived. This experiment has been tried on a large scale, and has failed, not because of any fault in the plan, but for the simple reason that the magnets were too much crowded. I made a demand on the company for $500, to alter the machine, but as they have already exceeded their subscription by $500, they thought best to give it up. But I have no idea of abandoning the experiment myself, as I have full confidence that a power equivalent to that of one or two men can be obtained with economy. I have a foundation for this calculation, and can prove by some recent discoveries I have made that in the present state of our knowledge, the economy of the power is limited somewhere about the strength of a single man. I have made a still further improvement, which was fairly tested in a machine completed yesterday, by which I can increase the power of a machine to a great extent without increasing the battery. I also made some time since certain important discoveries in magnetic electricity, which throw a vast deal of light on this subject. I showed one of them yesterday to Mr. Horn, in a new machine which works exceedingly well without change of poles. To his great surprise I stopped almost instantly a bar making a thousand revolutions [per minute] by bringing together the two ends of a wire which had no connection with the battery, nor with the wires around the magnet. This is a most singular thing, as the wire is entirely independent, and the machine stops much more suddenly than by reversing poles.



No. ——

ELECTRO-MAGNETIC ASSOCIATION.

. . . . *is entitled to*
. . . . *assignable Shares*
of Stock in the Association formed on Thomas Davenport's
Patent for Electro-Magnetic Machinery; the whole number of
Shares in said Association being three thousand, and subject to
the Articles of Association, dated March 3, 1837.

NEW-YORK, . . 1837.

For DAVENPORT & COOK, *Proprietors,*

Shares. Agent.

☞ Shares for sale by the Agent, EDWIN WILLIAMS, No. 76 Cedar-street, New-York. Present price of Shares Dollars, payable in cash.

STOCK CERTIFICATE OF ELECTRO-MAGNETIC ASSOCIATION.

[*Fac-Simile of Original in possession of W. G. Davenport.*]

I have still more recently made a more important discovery than this last. It does not relate at all to change of poles or cutting off the current, but is simply a method of increasing the power of the magnet. I will engage to make any machine of yours in five minutes time half as strong again, or forfeit the value of the machine (the battery shall remain the same). I feel very sure the power will be useful to the extent I have above named, but for reasons which I can make conclusive to any one I do not believe in its *indefinite* increase.

FREDERIC COOMBS.

[*From a photograph in the possession of Stephen D. Field.*]

I am now under obligations to no one here, and before I get up another interest I should like to know your views. I believe it would be for your advantage and mine, and contribute much to the success of the experiment, if our interests should be united. If you will make me a reasonable offer, I will take hold with you heart and hand, and there is no question but that in a short time we could make an excellent business of it, as we could cover the whole ground. Please write me immediately.

Respectfully yours,
CHARLES G. PAGE.

Acknowledging the receipt of this letter, Davenport replied briefly on Nov. 2, stating that he was "not in a situation to make or receive propositions relative to a union of interests," inasmuch as the ownership of his invention was largely vested in the corporation which had been organized to exploit it.

HOW TO DISPOSE OF THE INDIANS.

Secretary of War Proctor's mail is burdened with letters from cranks making suggestions as to the conduct of the Indian campaign. One correspondent proposes to exterminate the entire Sioux nation or a large part of it by establishing an electric plant at Pine Ridge and stretching a wire around the hostile camp. Then, turning on the current, the Indians are to be driven down to the wire, which is to be drawn closer and closer until contact with the wire causes wholesale destruction.

CURRIE'S NEW STORAGE BATTERY PLATE.

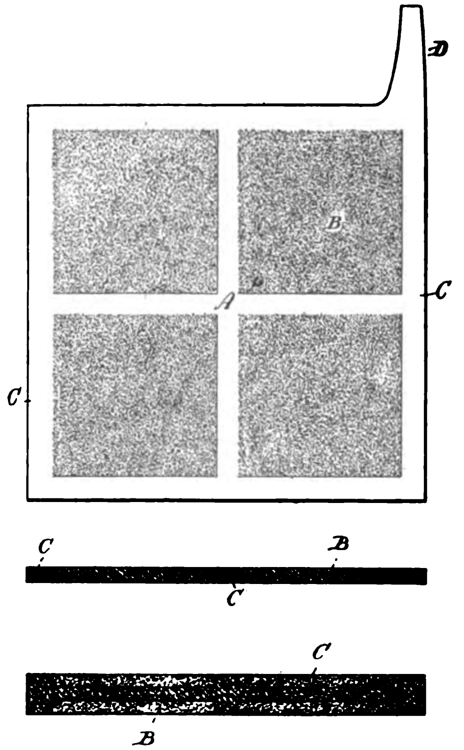
Our readers who are already acquainted with the work of Mr. Stanley C. C. Currie, electrician of the United Electric Improvement Co., of Philadelphia, will be interested in a new form storage battery plate recently patented by the same gentleman.

Mr. Currie's principal objects have been, first to dispense with the employment of separate frames, central supports, etc., for supporting the active material, and, second, to provide an inexpensive and durable means for supporting the active material as an integral part of the plate.

This is accomplished by pressing the plate at the edges, which are thus rendered compact. The accompanying engraving, Fig. 1, shows such a plate before, and Fig. 2, after the compression has been effected, Fig. 3 being a transverse section of the plate. As will be seen, the dense portions c are arranged around the periphery and parallel to the sides.

The method of making the plate is very simple. For this purpose a compound of lead—for example, chloride of lead or chloride of lead and zinc are melted together and then cast in molds so as to form the enlarged portions as well as the lug; the cast mass is then reduced by chemical or electrolytic action, or both, to a porous metallic state. The porous plates having enlarged parts are then placed between dies which compress and render the enlarged portions dense without in any way affecting the other portions of the plate.

After the enlarged portions of the plate together with the lug D are sufficiently compressed, the latter may be readily fitted for use as a binding-post in the usual manner.



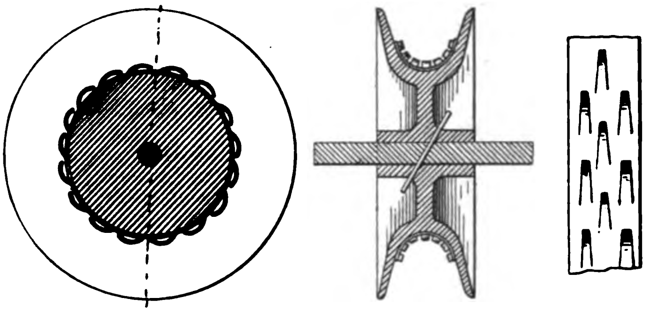
Figs. 1, 2 and 3.—Currie's Storage Battery Plate.

The portions of the plates which are compressed are rendered tough and dense, and as a consequence not only firmly support the active material, but also afford an efficient electrical connection between the conductors and the active material.

Iowa City, Ia.—The object of the suit of C. H. B. Carter *vs.* Iowa City Gas Light Co. is to have the affairs of the company placed in the hands of a receiver, as the property is liable to go to pieces through the conflict of interests.

LIEB'S ELASTIC TROLLEY WHEEL.

The operation of electric railways has developed the fact that while the trolley wheel is a most simple device for taking off the current from the overhead conductor, it labors under the disadvantage of affording only a small surface contact for the passage of the current, being reduced, in fact, to a mere tangent point. As a result, the resistance of the contact entails a loss of energy and at the same time causes a decided heating of the trolley wheel, which, in consequence, requires copious lubrication to keep it in good running order. Again, the solid trolley wheel at present employed has a tendency to jump, causing sparking, as well as noise and wear.



Figs. 1, 2 and 3.—Lieb's Elastic Railway Trolley.

In order to obviate all these difficulties and to secure better and more uniform contact between trolley and trolley wheel, Mr. Ch. H. Lieb, of this city, has designed an elastic trolley wheel, one form of which is illustrated in the accompanying engravings. As will be noted, the wheel is provided with a lining of brass in which springs are cut and curved outwards away from the plane of the sheet and having their ends curved inward again, as seen in Fig. 1, so that they cannot catch and be turned back by the trolley-wire when running in either direction.

It is obvious that the pressure of the trolley-wire on the springs compresses them so that there is relatively no shock or jar of the trolley against the wire, and separation of them is largely avoided; the shock of the trolley, also, when it comes in contact with the clamps by which the trolley-wire is suspended, is largely avoided. Thus the movement of the trolley along the trolley-wire is smooth and even, and sparking, wear on the parts, and noise are largely reduced.

It will also be observed that whereas in the usual form the trolley-wire comes in contact with only a very small arc of the trolley-wheel and at one point through which the contact must be made, in the new construction the flattening or compressing of the yielding surface of the wheel upon pressure by the wire or its attachments greatly enlarges the area of contact and also affords a number of points of contact, one or more of which at all times affords electrical connection, the effect being the same as though a series of trolley-wheels were used to make the same electrical connection.

A "LOST CHILD" TELEPHONE SERVICE.

The Missouri and Kansas Telephone Company is considering the matter of introducing what might be termed a "lost child service." It was originated in Indianapolis by G. J. A. Halford, now of the Youngstown, O., *Telegram*, a brother of Elijah Halford, President Harrison's private secretary. As soon as a child was lost the information would be telephoned to the central station. When a lost child was found this also would be telephoned. The finding would then be telephoned to the number that reported the losing. In some cases the child has been restored to its mother in twenty minutes after the loss was reported.

The service costs the telephone company comparatively nothing and no charge for finding lost children would be made to parents or friends. In other places where it has been used it has made many friends for the telephone company.

A PRACTICAL ELECTRIC RAILWAY CONDUIT.

BY

Stephen D. Field

THE subject of conduits for electrical railroads has occupied considerable space in this journal of late, and is one which is seemingly beset with many difficulties, judging from the elaborate constructions described, and the poor success attending their installation. The various details of conduit construction have been thoroughly worked out by cable railway engineers, and it only remains for the electrical engineer to supply the necessary insulating conductors and contacts to secure a sure and lasting installation for electric traction. I have endeavored in the accompanying illustrations to point out one design which I think will answer the purpose.

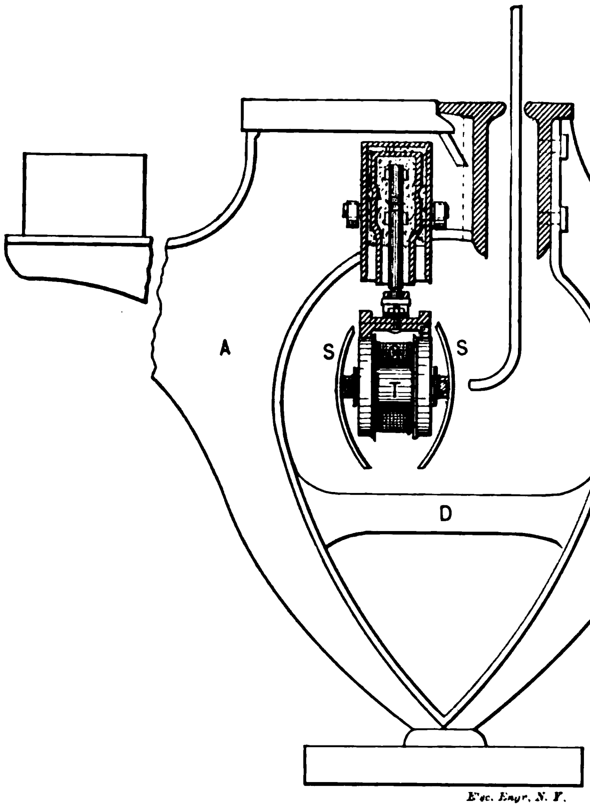


FIG. 1.—FIELD'S ELECTRIC RAILWAY CONDUIT.

The two factors most required in electrical conduits for railroads are perfect insulation and accessibility of parts. The conduit shown, has fittings so designed that all electrical attachments can be removed and renewed without disturbing the integrity of the conduit. The insulation may be so high that leakage will be inappreciable in any kind of weather.

The conduit frame, A, is made of cast-iron capped with steel at the slot. Insulation is provided by means of the well-known Brooks insulator, B, set at intervals of ten feet along the line of the conduit. The working conductor F is made in sections of twenty foot lengths arranged to "break joints."

Contact with the working conductor is obtained by what is termed a "magnetic trolley," T, which consists of two soft iron wheels fixed rigidly on a core which turns within a fixed coil, C; a current of 0.1 ampere passing through the coil causes the trolley wheels to adhere firmly to the iron working conductor. A spring is provided, just sufficient in strength to keep the trolley lightly against the conductor when no current is passing through the coil.

Immediately above each insulator a trap is provided through which the conduit may be cleaned and the insulators changed.

A brace, D, passes from side to side of the conduit at about one-third of its height; this secures rigidity of construction and allows of a lighter and less expensive yoke than is used in cable construction where no such device is permissible.

The switching is accomplished on the working conductor in precisely the same manner as on the surface track. The outer wall of the conduit may be used as one of the rails by allowing the flanges of the car wheels to run in the slot.

The lower portion of the conduit is so shaped as to provide adequate drainage, and it will be seen that water entering the slot falls clear of the working conductor and trolley. An insulating shield S encircles all the exposed metallic parts of the trolley, thus guarding against accidental contacts. Connection between the trolley and car is obtained by a hollow arm passing down through the slot, through which insulated conductors pass from the trolley to the car motor; the trolley is connected mechanically with the arm by a hollow wooden shaft hung in a gimbal.

The working conductor is of such a shape that it can be passed through the street slot and removed when necessary through the same opening. The joints in this conductor are bridged by strips or wires rivetted to their adjacent ends while current is supplied from an insulated trunk line laid parallel to the conduit, the working conductors being laid down in sections of five hundred feet and attached to the trunk line by branches containing cut-outs. As the trolley runs on the under side of the working conductor it is obvious that it always finds a clean surface to travel on; no dirt from the street can find lodgment there, magnetic adhesion provides an intimate contact with scarcely any weight and little resistance to progressive rotation.

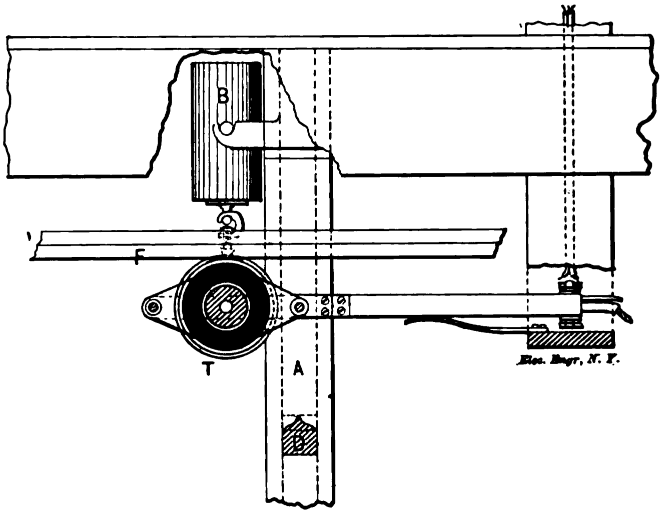

FIG. 2.—FIELD'S ELECTRIC RAILWAY CONDUIT.

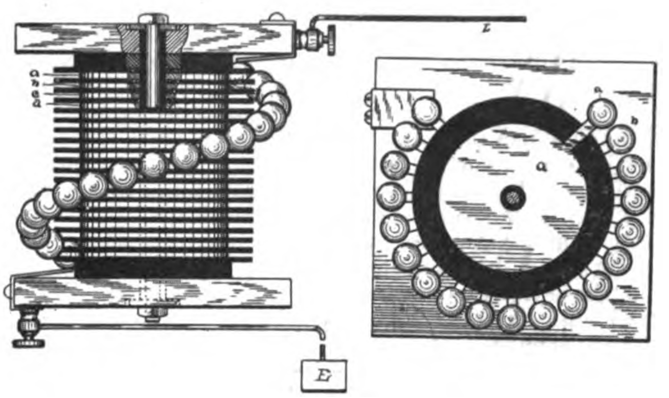
In any cold climate the conduit may be kept open by means of a pipe laid on either side of the slot through which hot brine can be pumped from the engine house. A very few degrees of artificial heat communicated from the pipe to the conduit is required to effect this result, while the efficiency of this device may be greatly extended by having relays of heating stations at proper intervals along the track. As this heating system is only in operation during the prevalence of extremely cold weather, it is probable that a few days per year will cover its total time of operation, and it would seem that the expense attendant upon its operation is too trivial for consideration.

I am of the opinion that a road equipped as indicated will be found to be far more reliable in operation and unobstructive in installation than is the case where the working conductors are carried in the air. This system can be introduced for less than the cable system, and worked with greater speed, freedom from interruption and at a less cost of operation.

THOMSON'S MULTIPLE BREAK LIGHTNING ARRESTER.

The permanent connection of lightning arresters to earth makes it necessary to provide means for preventing the continuance of the arc started by a static discharge. Numerous devices have been designed for this purpose, and among the more recent our readers will recall that of Mr. Charles Wirt,[1] in which the discharge was made to pass over a series of short insulated breaks to ground. In a patent just issued to Professor Elihu Thomson, a somewhat analogous arrester is described depending upon the principle that where a number of breaks are made in an electric circuit, or where a number of discharge-spaces are successively placed to be traversed by a discharge, the total distance traversed by the discharge as given by the sum of the spaces or breaks may be made much greater than the striking distance of a discharge between only two plates where a single break exists only in circuit; or, in other words, that an induced discharge of lightning or a sudden high-potential impulsive discharge will leap a number of striking-spaces in succession, and such a number of them as would be several times the length of a single space which would be leaped by the same discharge.



Thomson's Multiple Break Lightning Arrester.

Prof. Thomson has found, on the other hand, that when such discharge has taken place and the potential of the line is such as would tend to maintain an arc at the breaks or striking-spaces, such potential can readily be made insufficient to do so by multiplying the number of striking-spaces, and that an arc is much more readily maintained between two plates with a single wide space than between a succession of discharge points or over a succession of spaces placed in series and which the arcing tendency has to bridge, particularly if the discharging surfaces or metallic parts are of good conductibility for heat, the difference being the formation of a number of arcs between cold metal in succession as compared with the formation of a single longer arc over two metallic points.

Experiments have also shown that the metal pieces interposed between each successive break should have some capacity for static charge, as this facilitates the successive breaking down of the disruptive spaces by a lightning discharge or sudden static effect.

The manner in which these principles have been carried out in practice will be seen in the accompanying engravings, Figs. 1 and 2, which show respectively an elevation and a plan of the lower part of the arrester. As will be seen, it consists of a series of metallic plates, *a b c d*, etc., separated by insulating-washers, such as hard rubber, each washer projecting a little distance outside of the metallic plates. Each plate, as *a*, Fig. 2, is provided with a lateral projection and carries a discharge-terminal, such as a ball, which lies within a small space of the succeeding terminal plate, as *b*, of the series. At one end of the series is a connection to the line L, and at the other end is a connection to earth E.

The effect of arranging the plates, as shown, is to give each one a certain static capacity, while the discharge-points or balls can be adjusted as to distance apart by simply swinging the plates around circularly, so as to arrange the balls or discharging-points in a spiral fashion or a zigzag fashion around the column of plates. At the same time additional plates might easily be built up on top of the column by unbolting the centre bolt and stringing new plates and insulating-washers thereon, so as to increase the number of discharge-points and adapt the apparatus to working with higher potentials on the line.

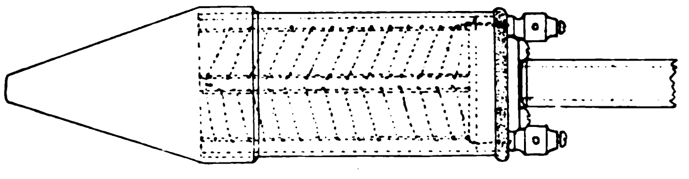
THE MINER ELECTRIC SOLDERING IRON.

The application of the electric current for heating purposes has already been introduced for a variety of purposes and the most recent of these is to the heating of soldering irons. Heretofore the irons employed for that purpose have been heated in open fires and the difficulty has always existed that the iron when taken out of the fire is usually too hot and then rapidly cools, so that its reheating is necessary.

With the electric current as the source of heat it is evident that a uniform temperature can be continuously maintained, and hence considerable time saved and greater convenience in working obtained. In order to adapt the current for this purpose Mr. Willard M. Miner, of Plainfield, N. J., has recently designed the soldering iron illustrated in the accompanying engraving.

This will be seen to consist of the usual soldering head having a cylinderical extension which contains two copper heating cores mounted upon a slate base. These cores are wound with No. 24 German silver wire, which is heated from the current led to the terminals.

An iron of this type is now undergoing trial at the works of the Tide Water Oil Company, at Bayonne, N. J., and during a recent visit we had occasion to observe the great convenience which the tool affords. In this establishment 36,000 cans are soldered each day and it is needless to say that every second of time saved is a material gain. The current is furnished by a dynamo and it is estimated that from four to six soldering irons of this type can be operated at an expenditure of one electrical horse power.



Miner's Electric Soldering Iron.

Having in mind the deterioration of the German silver wire with the continuous heating by the current, Mr. Miner is now experimenting with graphite as the conductor to be heated, by which he hopes to overcome the difficulty just mentioned. This material will allow of a much higher temperature being attained in a smaller space and will hence also be more economical of current.

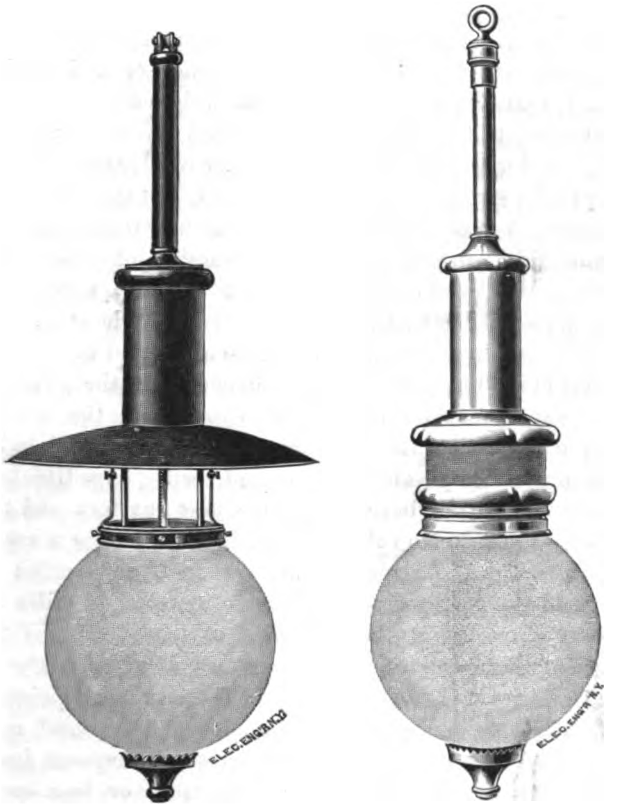
Port Arthur, Man.—A by-law providing $75,000 for an electric road between Port Arthur and Fort William has been passed by a vote of over 10 to 1.

---

[1] The Electrical Engineer, May 7, 1890.

NEW SCHEFBAUER ARC LAMP.

The accompanying illustrations represent the new lamps now being brought out by Mr. R. Schefbauer, of this city, Fig. 1 showing the outdoor lamp in operation, and Fig. 2 with the globe lowered for trimming. The lamp employed by Mr. Schefbauer for incandescent circuits is of the differential type and entirely without springs. For incandescent circuits of 110 volts, two of these are run in series with a small resistance, and for 220 volt circuits five can be run in series without resistance. The five ampere lamp gives 500 c.p., while taking the energy required by only five 16 c. p. incandescent lamps. The 1,200 c. p. lamp takes 7 amperes. For street illumination a 10 ampere lamp is employed having 2,000 c. p. This lamp can be inserted equally well in series circuits. It is provided with an automatic switch block, so that when the carbons are burned out, a resistance is inserted equal to that of the arc. The lamp is also adapted for use on alternating circuits. Fig. 3 shows the ornamental type adopted for interior.



Figs. 1 and 3.—Schefbauer's New Constant Potential Arc Lamp.

THE INFLUENCE OF THE ELECTRIC SPARK AND OF THE SURROUNDING GAS ON THE RATE OF THE ELECTRIC DISCHARGE.

In a recent number of the *Journal of the Physico-Chemical Society of Russia*, M. P. Bakhmetieff states that he has repeated the experiments of M. Naccari on the loss of charge undergone by an electrified body when close to an electric spark, placing the whole arrangement under a bell-glass and filling it with different gases. Generally speaking, the electric spark accelerated the discharge, but charges of positive sign were the more rapidly dissipated in carbonic acid, and in coal gas, while negative electrification disappeared the more rapidly in air, hydrogen, and oxygen. M. Bakhmetieff attributes these results to an unstable molecular allotropic modification of the gases by the electric spark which renders them conducting, but only to electricity of one particular sign. M. A. Nacarri, in the *Atti della R. Accademia delle Scienze di Torino*, Vol. XXV., states, with reference to some further experiments of his, that the influence of the electric spark on the rate of discharge of an electrified body is much diminished by the presence of vapor of water, alcohol, essence of turpentine, ether, and petroleum. He further calls attention to the fact that the presence of a piece of phosphorus near an electrified metal ball causes it to rapidly discharge. This phenomenon is, he says, apparently closely connected with phosphorescence, since it only takes place if the phosphorus emits a glow reaching to the electrified body. The phenomenon ceases in the presence of bodies, like essence of turpentine, which cause phosphoresence to disappear.

THE CONDUCTIVITY OF DISTILLED WATER.

Although the electrical conductivity of distilled water is extremely small, it was not found too small to be computed by Kohlrausch, who placed the value approximately at

0.000,000,000,025,

the conductivity of mercury being taken as unity.

W. Ostwåld has recently been contending in Gilbert's *Annalen der Physik und Chem.* (series [2], vol. xl., p. 735), that the electrical conductivity of distilled water is, in a great measure, due to the presence of carbonic acid gas held in solution. This gas is a well-known impurity in distilled water, sometimes causing it to give an acid reaction with delicate indicators. It can be removed by distillation over a considerable quantity of some base, as, for instance, pure lime.

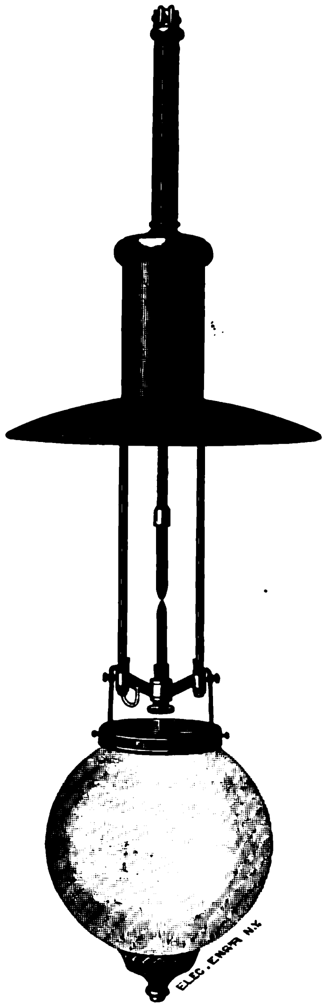


Fig. 2.—Schefbauer's New Constant Potential Arc Lamp.

Ostwald's paper is written to disprove the theories of Pfeiffer concerning the cause of the electrical conductivity of distilled water.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XI. NEW YORK, JANUARY 21, 1891. No. 142

> *"The man of true genius never lives before his time. Though he may catch a glimpse of the coming light as it gilds the mountain-top, long before it has reached the eyes of his contemporaries, and though he may hazard a prediction as to the future, he acts with the present."—Joseph Henry.*

UNDERGROUND ELECTRIC ROADS FOR NEW YORK.

THE rapid transit agitation in this city has now assumed formidable proportions, and it is safe to predict that 1891 will see steps taken to satisfy the necessities of the community. The Rapid Transit Commissioners have begun their work with every evidence of sustained zeal and good intent, and the press of the city is most outspoken in its advocacy of the popular needs. Particularly and specially must we commend the attitude of the perennially vigorous *Commercial Advertiser*, which, with an instinct, the keener, perhaps, for its long years of public service, has sprung to the front of the movement and has made "Rapid Transit!" its rallying cry for every New Yorker in whose breast is harbored any feeling of hope and pride and anxiety for the future of this great and imperial city.

In its issue of Friday, January 16, the *Commercial Advertiser* devotes a whole page to the discussion of rapid transit, accompanied by an editorial in review of the subject. Then for the first time, probably, in the pages of a New York daily were summed up the marvelous results attained by electricity during the past five years in America, as a motive power for street railway purposes. Such results we may briefly recapitulate for ourselves in the totals of nearly 300 electric roads, nearly 4,000 motor cars, over $50,000,000 of investment, and about 700,000,000 passengers transported safely per annum. The *Commercial*, however, does not commit itself to any advocacy, but, pointing to these figures, and to the recent successful underground electric railway work in London, suggests the inevitable inference that New York can meet its necessities by also putting in an underground electric road. In support of such an inference, it has also begun to collect the views of a number of leading electrical inventors and electrical engineers in this part of the country.

The arguments in favor of an underground road, and of its operation by electricity are so numerous and so important, that when duly counted and weighed they will be found irresistible. Our elevated system has been a great boon, but for the last five years has proved utterly inadequate to the strain of the crowded hours. At the same time no more such roads are wanted, for even now it is impossible in New York city to live beyond earshot of those that exist; so that even on the sole ground of the noise they make, no addition to the nuisance can be tolerated. To operate them by electricity would be a decided mitigation of their evils, but even then the capacity of the existing structures cannot be greatly increased. In the second place, no addition to the surface facilities, whether by cable or by any electric method, will expedite and shorten the journey between the business quarters and the uptown suburbs. No cable or electric road will be allowed to run through the streets at more than 6 or 8 miles an hour, and the elevated roads make from 10 to 12 miles an hour now, except at the extremes of load. Hence the choice of measures of relief narrows down quickly to some underground method, and as soon as that point is reached it is seen at once that a wholly underground road will be infinitely cheaper than one that half exposes itself and inflicts upon abutting property more or less costly burdens as evidence of its propinquity. The steam underground roads of London keep as near as they do to the surface because they must rise occasionally to breathe, and as State Engineer Bogart pointed out some time ago, ventilation in such underground steam roads, as in all long tunnels, is to-day the only big problem. But the underground electric road in London, while accentuating all the merits of the old steam underground roads, adds several new merits of its own, and one of the chief is the fact that with electric locomotives the ventilation difficulties are at once almost wholly removed.

Moreover, an underground electric road can easily do its own lighting and heating, the same small steel or copper bars that deliver current to the motors delivering it also to lamps and heating coils, while, if necessary, separate circuits can run through the tunnels, rendering the stationary lights there quite independent of the lights in or upon the trains. The passengers can also be transferred to and from the surface by electric elevators, of exactly the same nature as the hundreds already in use. In fact, in not one single detail does the proposed work involve difficulties that the electrical engineer has not now encountered and most successfully disposed of. It is simply a question of confidence on the part of the authorities, with sufficient concessions to encourage capital in carrying out the enterprise. None of us who travel daily up and down New York and see the vast masses of humanity in transit can have any doubt as to the financial success of a road honestly built and embodying the best engineering and electrical practice of the times.

ELECTRIC RAILWAY CONDUIT DETAILS.

Many of our readers will no doubt recall the rush of inventions that followed the first practical demonstration in electric lighting, and were brought forth mainly by the difficulties and necessities involved in the service. We can distinctly trace a similar tendency at the present time, in which inventors are putting forth their best energies to the solution of problems in electric railroading. Among these problems, the methods of operating the conductors below the surface of the earth are receiving not a small share of the attention, and to the many arrangements which we have already described we add this week another due to Mr. Stephen D. Field, who has long made this subject a special study. Mr. Field rightly assumes that a serviceable underground electric railway system must be strong enough to withstand all the adverse influences that are brought to bear upon it, and naturally turns towards the construction adopted for cable railways, as well as to that which experience has shown to be the best adapted for the purpose to carry out a thorough insulation of the conductors. Mr. Field employs a well-known and a long-tried type of insulator, so that in two important elements he is guided by the successful practice of the past. The method of making contact with the conductor employed by Mr. Field will also attract attention as being a neat method of securing intimate contact and of maintaining the conductor clean with the least wear upon it.

While thus the underground problems are not being neglected, the overhead ones still occupy the attention of not a few and, indeed, may well claim the attention of inventors. The overhead trolley wheel employed for taking a current from the conductor, simple as it is, embodies an enormous amount of thought, and is the result of many trials and failures. Even as it stands, it labors under difficulties which are inherent in any device of this kind made of a material having an unyielding nature. The smallness of the contact evidently introduces a point of resistance which results in the heating of the wheel with attending difficulties, and it was therefore highly desirable to increase the contacts and to reduce the shocks which a solid wheel encounters in its course. The device due to Mr. Charles A. Lieb, which we illustrate in another column, seems well calculated to avoid these difficulties and marks another advance in the working details of electric railroading.

HENRY'S ELECTRIC CAR GEAR.

The benefits to be derived from operating the motors on electric cars continuously, whether the car be at rest or in motion, though but recently called into prominence, is by no means a new departure in electric railroading. Among those who have devoted their attention to this branch, Mr. John C. Henry was probably the first to suggest this mode of operation and indeed to put it into practice more than five years ago. At that time, however, the opportunities which have since developed for the application of new ideas to electric railway practice were but limited. Now, however, the obvious advantages of electricity being recognized, the field presented for the application of meritorious devices is practically unlimited. An analysis of Mr. Henry's gear, which we illustrated in our pages last week shows it to consist of mechanism which permits of the car axle being directly connected to the armature shaft, at the same time permitting it to be disconnected without stopping the armature. At full speed, therefore, practically no loss in transmission is sustained through intermediate gearing, which with Mr. Henry's device acts as a solid connecting link. The practical tests of the motor we understand have been so successful that little doubt is entertained of its commercial adoption in the future. In addition to what has been stated in the descriptive article, it may be added that after the speed is got up, the armature shaft having been clutched directly to the internal gear, the rate of travel on a favorable track will easily compete with that of the fastest locomotive.

THE EDISON GENERAL'S ANNUAL REPORT.

Despite the fact that the annual meeting of the Edison General Electric Co. was held this week after our usual hour of press, we have succeeded in presenting a very full review in this issue of the remarkable statistics contained in the annual report. Such a document, at such a season, is a magnificent reply to those who, applying a pessimistic interpretation to disaster here and there, have doubted the stability of the electric light and power industry as a whole and have insisted that there was no health in Israel. We commend the report to our readers for careful perusal, so that if passing clouds have perturbed them they may breathe freely and take courage again. Summed up briefly, the report shows a growing business of $10,000,000 per annum, orders on hand for six months for a working force of 6,000 employees, net earnings for the year of 8 per cent. on the total stock, and gross profits, allowing depreciation, &c., of $1,896,177. It is noteworthy that the Edison Electric Light Co.'s net and undistributed receipts for the year were just over $1,000,000, and as the General Co. is understood to own over 99 per cent. of the Electric Light Co.'s stock, that sum might in reality, it would seem, be added on to the gross profits in computing the actual yield of the industry. The apparatus sold from Schenectady shows an increase of 117 per cent. over the preceding year, and the product of the East Newark lamp works has increased 64 per cent., while the capacity has just been raised from 11,000 to 25,000 lamps per day.

Storage Battery Improvements.

To obtain lightness and solidity of form with long life of the plates has been the constant dream and aim of the storage battery maker, and the variety of forms designed with this object in view afford a valuable example of the evolution of an idea in seeking to accomplish a given result. Among the methods tried has been one in which the lead grid has been entirely avoided. In such plates as made heretofore the mass of material was uniform in texture throughout the plate, but we illustrate in this issue a departure in this direction due to Mr. S. C. C. Currie. This inventor has sought to secure lightness with strength by producing a plate entirely of active material in which the supporting frame consists of a compressed active material, while the additional working part itself forms a body with the other and is in direct contact with it.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—X.

(*Copyright. The Electrical Engineer.*)

BY

Herbert Laws Webb

To return to our specific example of the test for insulation resistance. The behavior of the spot should be carefully watched, and at the end of one minute from the time of turning on the current the exact deflection should be noted. This deflection serves for working out the insulation resistance by comparison with the galvanometer constant; the figures for insulation resistance are generally stated to be "after one minute's electrification."

We will assume that the cable being tested is 2,640 feet long and that the deflection after one minute is 60 divisions on the scale. The constant of the galvanometer being 30,000, the absolute insulation resistance of the cable is $\frac{30000}{60} = 500$ megohms. As cables vary in length it is obviously useless, for purposes of comparison, to know the insulation resistance of a cable without also knowing its length, and even so it is not convenient to have to refer to two separate quantities; therefore it is usual to speak of the resistance per unit of length, and the insulation resistance per mile is the figure by which we can best judge of the actual condition of a cable.

In the present case the absolute insulation being 500 megohms and the length 2,640 feet, or .5 of a mile, the insulation resistance per mile will be 500 × .5 = 250 megohms. If the cable were 5 miles long and gave the same deflection the insulation per mile would be 2,500 megohms.

The insulation resistance per mile is always found by multiplying the absolute insulation, or the insulation for the whole piece, by the length; if the length is less than one mile the insulation per mile will be less than the absolute; if the length is greater than one mile the insulation per mile will be proportionately greater than the absolute. Thus if a piece of wire one-tenth of a mile long showed an insulation of 10,000 megohms, its insulation per mile would be 1,000 megohms. If a cable 10 miles long showed an absolute insulation of 100 megohms its insulation per mile would also be 1,000 megohms.

In testing long submarine cables it is usual to keep the current on for a number of minutes, sometimes for half an hour, noting the deflection at the end of each minute. The electrification and general behavior of the cable under test can then be observed with care. After the zinc current has been on for thirty minutes the cable is put to earth for five or ten minutes and the discharge or earth readings are noted; then the copper pole of the battery is applied and a set of readings taken, after which the cable is again put to earth and the discharge noted at intervals as before.

With short cables it is scarcely possible to make such long tests unless the battery power employed is very great or the galvanometer extremely sensitive, as the deflection obtained from a short cable of high insulation is so small, that, at the usual rate of electrification, there would be no deflection at all, or else a stationary one, long before the thirty minutes' readings had been taken. Nor is it necessary to make such elaborate tests on short cables, as if there is any defect present it will be revealed by a few readings or by taking reversals, as previously explained.

In testing cables or wires insulated with homogeneous compounds in a factory they should always be immersed in water kept at a definite temperature during the whole time, not less than two or three days, that the cable is submerged previous to the test. The usual standard temperature to which cables are subjected to in factory tests is 75 deg. Fahrenheit. This is a higher temperature than they are likely to be affected by when in use, the conditions being purposely made unfavorable to the cable in order that any possible defects of manufacture, which might not show up at once under ordinary conditions, may be revealed before the cable is accepted and put into use.

In testing telephone cables containing 50 or 100 conductors it is necessary to test each wire separately for insulation and a certain number for capacity and resistance. As a general rule, one minute's reading is considered sufficient for each conductor, as a cable which practically depends upon the soundness of the lead sheath for its insulation will show very quickly whether the condition of the cable is good or bad. Another reason which renders readings with different poles of the battery a poor guide to the condition of an underground cable, insulated with fibrous material, saturated with paraffin or insulating compound, is that the insulation is affected by heat to a very considerable extent, and it is also very quickly lowered by the presence of the smallest amount of moisture in the cable. But by whichever cause the insulation is lowered, the readings with opposite poles of the battery will be different, and therefore no clue is really afforded to the actual cause of an unsatisfactory test on a cable of this class; it may be either heat or moisture, unless, of course, there exists an absolute certainty that the cable is nowhere subjected to undue heat. If, however, moisture once gains an ingress into a cable insulated with fibrous material, the insulation will fall very quickly and the entire cable will soon be practically dead grounded, owing to the rapid absorption of moisture characteristic of such substances.

The insulation of a telephone cable should be fairly regular throughout, each conductor giving about the same insulation, but this is rarely the case, even when the average insulation is very high. For this reason the average of all the conductors is always taken as a guide to the general condition of the cable. A certain limit should be set, below which no conductor is to fall, as the average insulation may be up to the mark owing to high results from a number of the conductors, while others may test so low as to indicate the existence of a fault. As a general rule, if the insulation of a telephone cable is reasonably high and fairly uniform throughout, the condition of the cable is good. With a very high insulation there may be apparently great irregularity between the different conductors, owing to the difficulty of reading very small deflections under the ordinary conditions of testing; if, for instance, the insulation varies from 5,000 to 10,000 megohms per mile it may safely be assumed that there is nothing wrong; If, however, the majority of the conductors show an insulation of 500 to 700 megohms per mile, and about eight or ten conductors show a much lower insulation, ranging say from 30 to 100, while the average of the whole cable would be but slightly lowered by these few weak conductors, still they would indicate the existence of an incipient fault, which might in a short time develop sufficiently to seriously affect the condition of the whole cable. The uniformity of the test is therefore the best indication of the soundness of a cable of the description we are discussing.

In testing telephone cables for insulation all the conductors, except the one being tested, must be grounded; otherwise some of the conductors, those toward the centre of the cable, will have the benefit of a greater thickness of insulation than others. This is usually done by lacing a fine bare wire among the binding posts on the terminal head and connecting it to the iron box or to the lead pipe, sufficient slack being left in the wire for it to be pulled clear of each binding post in succession as the lead is connected.

One minute's reading with the zinc current is taken on each conductor and the insulation is worked out by the deflection obtained at the end of the minute, according to the method previously described. In calculating the average insulation of the cable, the deflections must not be added up and averaged, and the average insulation worked out by the average deflection; the fairest method is to take the average of the insulation resistance of all the conductors.

To instance the different results given by the two methods if the deflections are at all irregular, let us assume that we are testing a cable 2,640 feet long. The constant of the galuanometer is found to be 30,000 and the first five wires give deflections after one minute's electrification of 30, 50, 30, 10 and 30 respectively. The average deflection would be 30, which would give an insulation of 1,000 megohms absolute and 500 megohms per mile. Working out the deflections separately, however, we get a different result:

No.	Deflection.	Insulation Absolute.	Resistance Per Mile.
1	30	1,000	500
2	50	600	300
3	30	1,000	500
4	10	3,000	1,500
5	30	1,000	500
Average Insulation,		1,320	660

Thus it is obvious that unless the deflections are extremely regular throughout, the average insulation should not be determined by the average deflection, as would readily occur to most, but by summing the insulation resistances of all the conductors and averaging. This would be very laborious if every conductor gave a different deflection but it generally happens that the same deflection occurs frequently in a test on a hundred conductor cable, which considerably lessens the labor of working out the test and obtaining the average insulation.

In some cases it simplifies matters to work out results by logarithms. As an example, suppose the cable being tested is 3,475 feet long, and that we are working with a constant of 42,500. The first deflection after one minute's electrification is 37; to find the insulation absolute and per mile of this wire we proceed as follows:

Log. 42,500=4.62838
" 37 1.56820
3.06018 = 1,148 megohms absolute.

Turning 3,475 feet into decimal parts of a mile we get .658; the log. of this added to the log. of the absolute will give the insulation per mile, thus:

Log. 1,148=3.06018
" .658=$\bar{1}$.81822
2.87840 = 756 megohms per mile.

When dealing with large numbers it is no doubt more convenient to use logarithms, and, with one man to do the figuring and another to look up the logarithms and numbers, it is no doubt quicker than working out by division and multiplication. It must always be remembered that in multiplying by logarithms the logs. are added, and in dividing, subtracted.

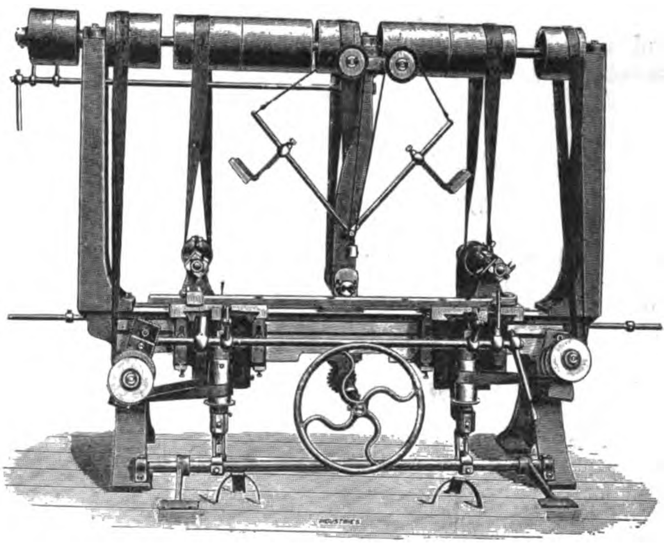
A BROKERS' TELEGRAPH SERVICE.

President Baker, in his address to the members of the Chicago Board of Trade, at their annual meeting, January 12, charged the Western Union Telegraph Company with fostering bucket shops, and said that he believed that the time is ripe for the members of the several exchanges whose relations are intimate and important to establish their own telegraph lines. A committee of five was appointed at the meeting to formulate such a plan as suggested by President Baker.

Second Lieut. **Frank Greene**, Signal Corps, now on duty at Santa Fé, New Mexico, has been ordered to proceed to the following points and make a thorough inspection of the Signal Service stations there: Forts Sill and Reno, Oklahoma Territory; Dodge City, Kan., and Pueblo, Col.

MACHINE FOR SHAPING AND BORING TELEGRAPH POST ARMS.[1]

The accompanying illustration represents an ingenious machine which has been lately made by Messrs. John Pickles & Son, Hebden Bridge *via* Manchester, for preparing telegraph post arms. These arms are usually made from the best selected English oak, and vary in length from 2ft. to 4ft. They are in the first case planed on the four sides by means of a special planing machine made by the above-named firm. They are then sawn to the exact length required by means of a double cross-cut sawing machine made specially for the purpose. The arms are then passed along to the machine we now illustrate. This machine is provided with a fence bar, in which the arms are held fast by a novel screw clamp. By means of the hand lever shown to the right the arm is carried, by the slides, between cutters revolving at a high speed. These cutters complete the end chamfering, and at the same time the central hole is bored by a revolving boring bit. After this the slide carrying the arm is moved up against an adjustable stop, and the operator turns the large hand wheel. This is connected by bevel and other gearing to the cutter headstocks, and causes the latter to move towards each other up to a given point in accordance with the length of chamfer required, which may be from 7in. to 17in. in length. The cutters revolving at a great speed take off the chamfer on both sides of the arm and also at both ends at the same time. The bars shown at the ends of machine have gauge stops fitted for giving the length of traverse required. The headstocks are after this rapidly wound back to their first position and are ready for the next operation. The operator then places his foot on the foot lever, which causes the two heads carrying revolving boring bits to rise and bore the holes at each end required for fixing the insulators. The pads connected with cords and levers on the central standard are intended to prevent the boring bits splintering the wood when coming through the top side.



Machine for Making Cross Arms.

It will be seen that the machine is quite self-contained, and has the driving shaft placed overhead and supported upon standards fixed to the main bed. The arrangements for dealing with the various lengths of arms have been carefully thought out. At the official test of the machine in the presence of the purchasers the wooden arms were finished at the rate of three per minute.

---

[1] *Industries.*

ON THE ARRANGEMENT OF VATS IN ELECTRO-DEPOSITION.—II.

BY

Let us see now if it is possible to vary the consumption of energy while keeping the deposit constant. To keep the deposit constant it suffices to maintain the current unchanged. From (3) we see that with C constant the term $C\varepsilon$ cannot be changed but will also remain constant, the factor ε being practically a constant. We can, however, vary r or R, especially the latter. We may do this by varying either the conductivity of the solution itself, or the electrode surface (a), or the distance (l) between the electrodes, or all three quantities simultaneously.

Let us, for instance, double the surface ($=2a$) of the electrode, and place them only half as far apart($=\frac{l}{2}$), while we change the constituents of the electrolyte so as to reduce the specific resistance (s) one-half. We then have for the liquid resistance

$$\frac{l\,s}{2 \times 2 \times 2\,a} = \frac{l\,s}{8\,a} = \frac{R}{8},$$

and for the total resistance of the cell (neglecting the change in r);

$$(r + \frac{R}{8}).$$

The energy consumed will be

$$W' = C^2\,(r + \frac{R}{8}) + C\,\varepsilon \qquad (4)$$

which is less than before, since

$$W - W' = \left[\,C^2\,(r + R) + C\varepsilon\right] - \left[C^2\,(r + \frac{R}{8}) + C\varepsilon\right]$$
$$= \tfrac{7}{8}\,C^2\,R, \qquad (5)$$

this value (5) representing the saving effected by the change.

We will now assume eight of these low resistance cells to be placed *in series*. The resistance of the connections is supposed to be negligible.

The energy required will be

$$W'' = 8\ W' = 8\ \left[C^2\,(r + \frac{R}{8}) + C\,\varepsilon\right]$$
$$= 8\,C^2\,r + C^2\,R + 8\,C\,\varepsilon \qquad (6)$$

As the same current passes through all eight cells, the total deposit will be eight times what it was with the small cell. The energy consumed has, nevertheless, not increased to eight times its original value. Comparing (3) and (6) we find the difference to be only

$$W'' - W = (8\,C^2 r + C^2\,R + 8\,C\varepsilon) - (C^2\,r + C^2\,R + C\varepsilon) = 7\,(C^2 r + 7\,C\varepsilon) \qquad (7)$$

In practice the distance between the anodes and cathodes is generally fixed and the most convenient way to reduce the resistance is by increasing the surfaces; which can be done by connecting more pairs of plates in parallel, or, what is equivalent thereto, by connecting several cells or "vats" in parallel.

Let us therefore connect in parallel circuit n cells or vats, each having the same values of r, R, and ε as the first one considered. The joint resistance of the group will be $\frac{1}{n}$ of each vat taken alone. Hence we can add n such groups in series and the total resistance of the whole will still be only equal to one vat. As we desire to maintain the current (C) constant it will be divided equally between the n groups or series of vats, each of which will receive $\frac{1}{n}$ of the total current, and its depositing rate will be only $\frac{1}{n}$ of what it was in the case of a single vat. But, as there are n^2 vats in all, the total rate of deposition will be $n^2 \times \frac{1}{n} = n$ times greater than before, or in direct proportion with the number of vats *in series*.

Let us now see how much power is consumed. The current through each vat being only $\frac{C}{n}$, the energy consumed in each vat is

$$\frac{C^2}{n^2}\,(r + R) + \frac{C}{n}\,\varepsilon; \qquad (7a)$$

and the total power required for the n^2 vats is,

$$W''' = \frac{n^2\ C^2}{n^2}(r + R) + n^2\,\frac{C\varepsilon}{n}$$
$$= C^2\,(r + R) + n\ C\ ; \qquad (8)$$

which differs from the power required for one single cell (3) by only

$$W''' - W = [\,C^2\,(r + R) + n\ C\varepsilon] - [\,C^2\,(r + R) + C\varepsilon]$$
$$= (n - 1)\ C\varepsilon \qquad (9)$$

The rate of deposition is, therefore, increased n times, while the power is increased as many times as (8) contains (3), that is,

$$\frac{C^2\,(r + R) + n\ C\varepsilon}{C^2\,(r + R) + C\varepsilon} = 1 + \frac{(n - 1)\ C\varepsilon}{C^2\,(r + R) + C\varepsilon} \qquad (10)$$
$$= \frac{W''' - W}{W} + 1. \qquad (11)$$

These equations are general and apply to all cases of electro-deposition. To obtain the net value of the ratio (10) in the case of copper deposition, we must now return to the factor ε, and consider it more closely. When the anode is of copper, and worked with the usual acidulated sulphate solution the polarization is all but inappreciable. Under normal conditions, for each atom of copper deposited on the cathode from the solution there is a corresponding atom dissolved from the anode, and added to the solution. According to thermo-chemical theory, therefore, the two actions should compensate each other perfectly and there ought to be no polarization whatever. In practice it is a very small factor. J. T. Sprague places its value at .02 volt. In his paper on electrotyping before the (then) Society of Telegraph Engineers and Electricians in April, 1885, Capt. H. R. Sankey, R. E., states that the value of the counter E. M. F. (ε) varies from .005 to .016 volt. Mr. A. F. Delafield[1] gives a still lower value (.002 volt). The writer has found that in electrotyping, with proper care, the polarization can be kept below .01 volt. In some cases it may rise to a value several times higher. This is apt to occur when the solution becomes altered in character or when the anode and cathode surface vary in relative areas. If the plates are of unequal surface, or, what amounts to the same thing, if the circulation of the electrolyte is unequal, there will be a tendency either to evolve oxygen at the anode, or hydrogen at the cathode. If the current density be excessive, both actions may occur simultaneously. If the former occurs alone the solution becomes impoverished, if the latter, it becomes enriched. In either case the resulting polarization adds to the loss of potential by increasing the factor ε.

The polarization is also influenced by the kind and amount of impurities found in the copper of the anode plates. For each case there is a maximum current density above which the polarization increases rapidly. When the solution is warm and diffusion is further aided by agitation the polarization does not increase so early or so rapidly, as the current density is raised.

---

[1] THE ELECTRICIAN & ELECTRICAL ENGINEER, August, 1886.

By connecting more vats in parallel to increase the surface, the current density is reduced, and the conditions are more favorable to low polarization.

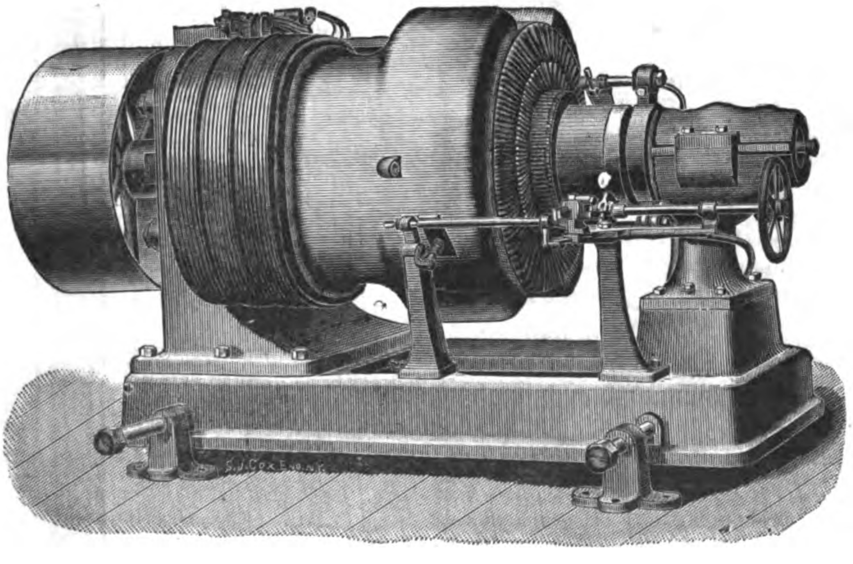
The value of ε, for the case of copper, is in any event so small that the fraction in (10) will always be small. The value of $\frac{W''' - W}{W}$ will, it is evident, increase with the number of vats; the rate is, however, very slow. When n is taken $= 100$, which means 1,000 vats, this fraction, using actual data, will usually reduce to 6 or less, making the total $(1 + 6) = 7$. With impure anodes, and varied conditions of working, the total (11) may rise to as much as 10. In other words the deposit would be increased 100 times and the power 10 times, as compared with a single vat. As a rough approximation the power would be $\sqrt{n}$ times that of one vat and the ratio of deposit to power would be as

$$n \text{ to } \sqrt{n} = \frac{n}{\sqrt{n}} = \sqrt{n}.$$

The power consumption, therefore, does not quite remain constant, as implied in the statement of M. Fontaine quoted at the beginning. Yet it increases so slowly with respect to the rate of deposition that the theory then advanced is certainly much nearer the truth than is the view of those who maintain that the power expenditure is the same under any and all circumstances.

THE NEW EDISON ARC LIGHT MACHINE.

As is well known, Mr. Edison has always advocated the use of the incandescent lamp for all kinds of illumination, including both interior and street lighting, and it was with the object of accomplishing the latter purpose that the well-known Edison "municipal system" was devised. In response, however, to the many demands made upon it for arc plants, the Edison General Electric Co. has now brought out a complete system of this kind, which enables it to furnish every desired kind of electric lighting and power apparatus of the nature named.



New Edison Arc Light Dynamo.

The new dynamo designed for the purpose, known as the Edison two core arc machine, is illustrated in the accompanying engraving, and derives its name from the design of the field magnets. Only two magnets are used, set at a slight angle, separating at the pole pieces to admit the armature, and approaching each other where they join the yoke. This construction is electrically the most efficient possible, for the large amount of iron in the field magnets and the short length of wire in the coils, together with the compact form of the whole machine keep the internal losses small.

The field coils are wound in sections, and slipped on over the cores; the terminals are then brought to binding posts on a connecting board above each magnet core. All the connections are thus easily accessible, and in case of injury to the winding the fault can be immediately localized and the injured section replaced in a few minutes.

A Gramme ring armature is used, with the core built up of alternate rings of soft iron and paper and held to the shaft by gun metal spiders. The armature winding forms a continuous coil of many turns around the core, and is connected to the commutator by copper strips soldered to loops left at equal distances around the circumference of the ring for this purpose. The strip connectors play an important part in the ventilation of the armature, acting as an exhaust fan, and keeping a current of air constantly circulating through the interior of the machine.

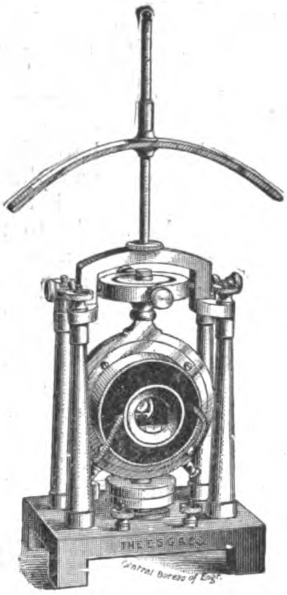
The commutator is built of hard drawn copper bars, insulated throughout with mica, and the insulation of all parts of the dynamo has received thorough attention. The regulator is attached directly to the dynamo base frame, where it is out of the way, and consists essentially of a small flat armature, pivoted near one pole piece, and a rack and pawl mechanism driven by a short belt from the dynamo shaft arranged to shift the brushes around the commutator in one direction or the other, as the governing armature is attracted more or less powerfully by the pole pieces. The field magnet thus is the controlling magnet of the regulator, so dispensing with all external regulating mechanism. Thorough lubrication of the machine has been provided for in the employment of the Edison self-oiling bearings. In these the oil is steadily fed to the bearings while running, they cannot clog nor run dry, they are dirt proof, and great savers of oil; while they require attention only at intervals of ten days to a month.

Two styles of lamps of improved design are employed in connection with the arc machine, the single lamp and the "triple" carbon. The latter takes the place of the ordinary double carbon lamp and maintains the lengthened period of burning by the employment of two upper positive carbons and a single flat negative carbon. The mechanism does not differ essentially from that of the single lamp.

All the other details which go to make up a complete arc lighting system have also been completely worked out, including switchboard, ammeter, lightning arrester, and other accessories.

THE FREY PORTABLE REFLECTING GALVANOMETER.

This instrument, the invention of Mr. Charles P. Frey, chief electrician of The E. S. Greeley & Company electrical laboratory, embodies the essential features of Thomson's reflecting galvanometer, and is extremely sensitive. Its principal feature is that it can be instantly prepared for use by releasing the coils, which are suspended by means of a universal joint, and thus require no leveling. When not in use the fibre suspended magnet and mirror, as well as the pendant coils, are securely locked by means of a compound bolt operated by one turn of an independent key, doing away with the danger of breaking the fibre, a danger to which the ordinary type of fibre suspension is extremely liable when at all roughly handled, and one which may be a serious annoyance.



Frey Portable Reflecting Galvanometer.

This galvanometer is especially adapted for rapid subway testing, since it may be rendered direct reading by attaching a pointer. For more delicate tests, by using a lamp, stand and scale, a high figure of merit may be obtained.

A STRIKE OF RAILROAD TELEGRAPHERS.

As a result of the refusal of the Chicago, Milwaukee and St. Paul Company to accede to the demand of the station agents and railway telegraph operators on the lines of that system, a strike was determined upon to begin Friday, Jan. 16. Grand Chief Thurston, of the International Order of Railway Telegraphers, sent out an order to every agent and operator in the employ of the road to send in his resignation, to take effect Friday, January 16, at 9 A. M. This course was taken by the men in order to protect their men, who would be liable for resulting damages had there been a strike without previous notice being given. There are about 450 who will go out. Chief Thurston says: "We are in splendid condition, and if necessary, can support these men for a year. Station agents and operators all over the country are rallying to the support of the movement, and we shall have ample funds to carry on the fight to a successful termination. I do not suppose our men quitting will interfere with the running of trains, but the trains will have nothing to carry. Nearly all the operators at way stations are agents. Now, when they quit, who will receive freight or sell tickets? The company cannot let incompetent men do that work."

Chester, Pa.—The stockholders of the Chester Electric Light and Power Co. met Jan. 12, in the office of the company on Third street and elected a president and board of directors, as follows: President, G. P. Dennis; directors, C. W. Perkins, F. G. Sweeney, Joseph Deering, D. P. Paiste, Joseph Messick, John McGolrick, William Burnley, H. B. Black, Hubert J. Riley, F. S. Hastings.

THE STEWART-HALL TRAIN ORDER SIGNAL.

There has for a long time existed in the minds of railroad men the conviction that railroading needed a simple, and at the same time effectual, train order signal. To meet this demand, Mr. Robert Stewart, Supt. of Telegraph of the Central Railroad of New Jersey, and Mr. W. P. Hall, the well-known inventor of the admirable system of the Hall Signal Co., have perfected the apparatus illustrated in the accompanying cuts. Their very ingenious signal was exhibited in operation to a number of prominent railroad men at Somerville, N. J., on January 15th.

The device consists of a semaphore, Fig. 1, or disc, placed alongside the track, a switch, Fig. 2, placed on the operator's desk, beside his telegraph instruments, and an indicator box on the opposite wall of the office, Fig. 3, a closed circuit battery being used. The semaphore is attached to a rotating armature which is held at safety when the circuit is closed, as shown at s, Fig. 4. It is also counter-weighted so that when no current is flowing through the magnets, the semaphore is brought to the position shown in Fig. 1. The details of the indicator are shown in Fig. 5 and at D, Fig. 4.

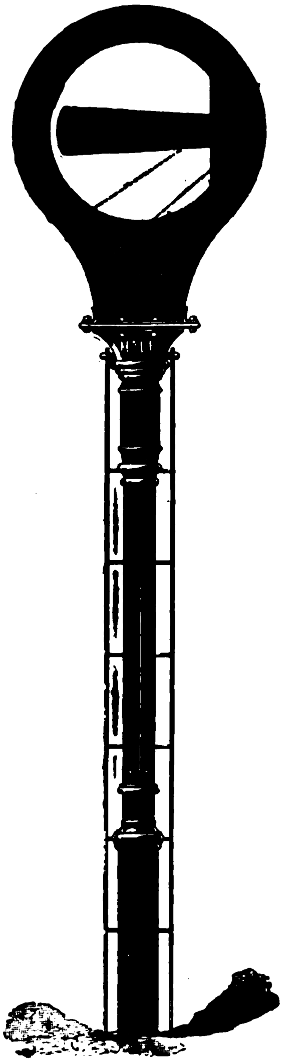


Fig. 1.—Hall Signal.

The object of this signal is to insure the delivery of orders to approaching trains. When the order is received, the operator throws the switch to the point marked "Danger," Fig. 2., thus opening the circuit and throwing the signal to "Danger," and this operation allows the drop in the indicator box to fall, which displays the words "Train Order," Fig. 4.

When the train is brought to a stand-still in front of the station, it is the first impulse of the operator to clear the track; he naturally moves his switch lever to the point marked "Safety," but the signal remains at danger, and in order to close the circuit, it is necessary for him to push the button on the annunciator, when he is confronted with the words "Train Order." This reminds him that he has an order for that train. He delivers the order, returns to the office, pushes the button on the indicator, closing the circuit, and causing the signal to drop to the point marked in dotted lines in Fig. 1. At the same time the annunciator is cleared. A complete train order station consists of signals to cover the track from opposite directions, as east and west.

It will thus be seen that should the operator forget that he has orders, once his signal is set, the train will stop and not proceed until he has closed the circuit at the indicator box where the drop reminds him what the train is detained for.

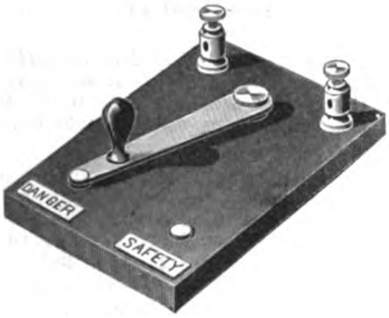

Fig. 2.—The Switch.

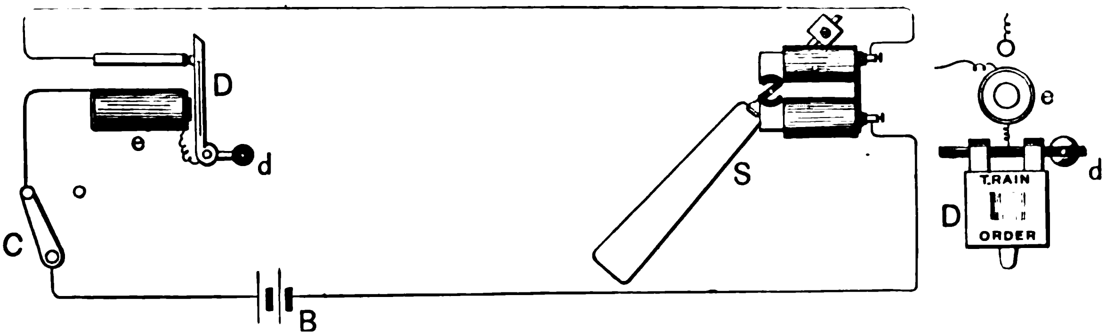
The value of this device will be apparent when it is considered that the person in charge of a small railroad station plays the role of telegraph operator, ticket seller, and baggage master, which, with the various details attached to each of these offices, makes him liable to commit serious errors.

There is probably no part of the duties of a station operator so liable to be overlooked as train orders, and where considerable time elapses from the moment he has received orders, and the arrival of the train for which they are intended, the danger of their being forgotten is increased. Many serious accidents have been occasioned by train orders being forgotten, but by the application of this system the station operator is relieved of the fear that he is liable to forget. The moment he makes the simple movement of a switch, he goes about his work knowing that everything will be attended to.



Figs. 4 and 5.—Diagram of Circuit, Stewart-Hall Train Order Signal.

While this appliance is intended for train order signaling, it may be used as a station starting signal, the drop in the station showing in all cases the position of the signal even should it be out of sight of the operator. It can also be used to advantage on many roads where an extensive system of signals is unnecessary.

THE TRICYCLE IN MILITARY TELEPHONY.

In a recent issue *La Lumière Electrique* described the employment in military telephony of a tricycle, adapted either for traveling on roads or for use as a water velocipede, without the necessity of undergoing any change in its mechanical construction. The wheels, instead of the usual pattern, are formed of three large hollow bi-convex discs of sheet iron, and thoroughly watertight. They are fitted with small copper floats, which, while not in the way for road work, act as paddles when the machine is afloat. The hollow wheels serve to support the construction on water. A small drum is carried, on which is coiled from 100 to 200 yards of a tinned copper conductor, insulated with gutta-percha and double braided. A small board, conveniently fixed, carries a portable telephone or a Morse sounder. The telephone is preferable, as it can be carried in the pocket, requires no regulation, and can be attached to the chin-strap of the helmet or other military head gear. For river or lake work one Leclanché cell is used, but on salt water the following type of cell is employed. Two small electric light carbons, connected metallically, are secured in grooves cut in the opposite faces of two pieces of cork. Between the carbons, and through the centre of the cork, a thin rod of zinc is passed, and to it is attached, by a wire, a copper plate. The carbons are connected to the instrument board. When required for work the cell is placed in the water. The speed attained with this tricycle has been on land from 9½ to 12½ miles, and on water from 2½ to 4½ miles per hour. It is said to work very easily, and experiments with it, recently conducted at Marseilles, are reported to have resulted very satisfac-

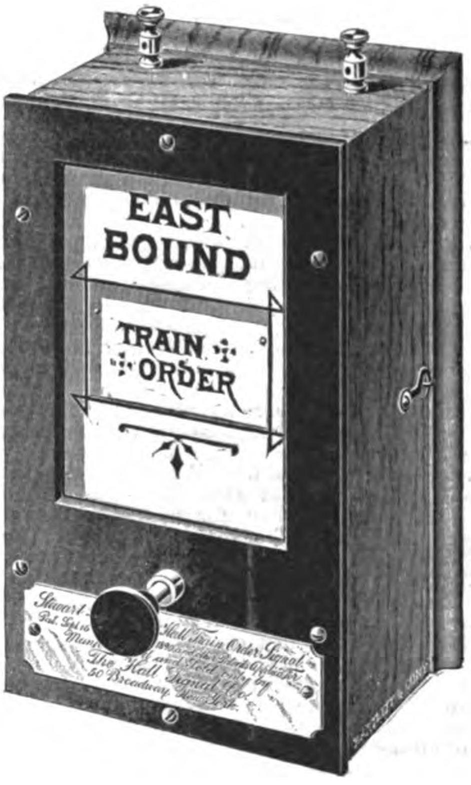


Fig. 3.—Train Order Signal.

torily. Its employment is described as likely to be of service to detached bodies of troops carrying with them no pontoons, possessing no means of fixing up a temporary bridge, and engaged on duties which render necessary permanent communications with headquarters.

Home Correspondence.

PITTSBURGH.

Electric Railway for Clarksburg, W. Va.—Electric Railway Work in Pittsburgh.—Taxing Street Railways.—Lighting at Uniontown, Pa.

A COMPANY has been chartered in Clarksburg, W. Va., for the purpose of building and operating an electric railway. The company is composed principally of the stockholders of the Clarksburg Electric Company, which is now operating an electric light and power plant in that city.

The transformation of the motive power on the different street car lines in this city from animal to electric power is still rapidly progressing. Unless something unforeseen occurs, two more electric street car companies will have started within the next two weeks. They are the Duquesne Traction Company and the Birmingham Traction Company. The former is now occupied with putting the last finishing touches to the overhead work on its many lines throughout the city. A number of the cars have already arrived; the power house has been finished for some time and the machinery has also been placed in position. Had it not been for the unfortunate snowstorm, which delayed everything a few weeks ago, the road would undoubtedly be in operation today; but as the effects of that have now also been overcome everything is being put into shape for the first car to be running within a very short time. The management of the Birmingham Traction Company has completed everything except to put the motors on the trucks when they will also be in a position to send their horses, which they are now still using, to pasture, and give their patrons rapid transit with electric motors.

Most of the Pittsburgh street car companies, especially those operated by electricity, are now dividend paying corporations and it appears that the city authorities think the city ought to have some of these large earnings. It is perhaps on that account that the city comptroller has lately addressed communications to the authorities of all the larger cities in the country for the purpose of obtaining from them information as to how much this city might be able to make from a taxation of the many electric, cable and other street car lines now running here. The comptroller has already received replies from Cleveland, Baltimore, Providence, R. I., St. Louis, Buffalo, Milwaukee, Newark, N. J., Cincinnati and Boston and from all of these it appears that Pittsburgh really is behind most cities in the way of getting revenue from its street car lines. As soon as the comptroller has heard from a sufficient number of cities to form an estimate of the whole, he will make his report to the city council and the result will in all probability be that street car companies in this city will also have to pay a tax.

The Heat and Light Company, of Uniontown, and the Electric Light and Power Company, of the same place, have formed a consolidation under a New Jersey charter and the new corporation will be known as the United Light Company.

The Second Avenue Electric Street Car Company has ordered four new cars to accommodate the increasing traffic of the road.

PITTSBURGH, Jan. 10, 1891.

Letters to the Editor.

THE DOUBLE WIRE SYSTEM DURING THE RECENT STORMS.

In your editorial of Dec. 31, 1890, page 723, you have, perhaps unintentionally, done injustice to the double wire system of electric traction.

The day after Christmas the entire State of Pennsylvania was visited by a most severe snow fall, varying in depth between 15 and 20 inches. At Sunbury the snow fell something over 20 inches during a continuous period of 17 hours. The road running between that town and Northumberland is built on the two-wire plan, and is equipped with the United Electric Traction Company's motors of the 1890 type, 30 h. p. each, geared to a single axle, only, for traction. The road includes a large number of very short turns and grades of over six per cent., two of them having sharp curves near the top. The road also labors under the disadvantage of having the trolley wire 18 feet high at the railroad crossing, while through the bridges it is so low that the trolley head goes within four inches of the trolley-boards on the roofs of the cars.

In spite of the fact that the local superintendent, Mr. Chase, had only just been put in charge two days before, and was not yet acquainted either with his employés or with the facilities of the town, he was able, with the assistance of Supt. Dodge, of the United Electric Traction Co., to open his line so that cars were running, though irregularly, throughout the day, and by Friday evening the cars were making through trips very nearly on time between the extreme limits of the road. This was done in spite of the fact that sand-boxes which had been ordered several weeks before had not arrived and they were obliged to make a slight use of sand from boxes standing on the front platforms.

Inasmuch as nearly all the single trolley roads throughout the country were snowed up, this is a particularly interesting record, and we feel sure that you will be glad to record it as a vindication of at least one double trolley system.

J. STANFORD BROWN,
United Electric Traction Co.

NEW YORK, Jan. 12, 1891.

Literature.

The No. XI. Pocket Handbook of Useful Information, Price List, Telegraph Code, etc. Relating to Lead Covered Electric Cables, Insulated Wires. etc. By Joseph W. Marsh. July, 1890. The Standard Underground Cable Co. Pittsburgh, New York and Chicago.

ALTHOUGH the electrical trades afford much scope and opportunity for the catalogue maker, the occasions are rare when trade publications call for more than a passing notice. We would, however, be lacking in duty if we failed to call to the attention of our readers the excellent pocketbook which lies before us, and which we are sure will occupy a prominent position among the handy volumes of the electrical engineer.

Underground work has reached such proportions in this country that a thorough knowledge not only of the materials, their qualities and various applications, but the manner of their laying has become a necessity to the electrical engineer. In the handy volume before us we find complete descriptions of the various types of Waring electric light, power, telephone and telegraph cables, both lead covered and armored, and for all classes of service, overhead, underground and submarine, together with their weights, thickness of insulation and the various other data which are generally required to be known in drawing up specifications. Upon all of these the well-known Waring insulating material is employed. In addition to this, however, we have full descriptions of the various other kinds of wire, rubber covered, bare, magnet and annunciator wire, etc., manufactured by the company, as well as the weather-proof line wire. On the latter the well known insulation "Ozite," or Waring compound, is employed. Each of these is accompanied by a description relative to its proper use and method of placing.

Regarding the mixture of tin with the lead covering of cables, we note that the manufacturers doubt the value of this application, though they are prepared to furnish the covering to any desired specification.

We also find some interesting records of experiments made to determine the self-induction of cables carrying alternating currents of 16,000 alternations per minute. In one of these tests the out-going and returning cables were placed in the same 3-inch iron duct; in the next the out-going and returning cables were placed in separate ducts. The total length of the cable in each circuit was 8,800 feet. In the former case it was proved that the loss due to self-induction per ampere per thousand feet of cable amounted to .06 volt, while in the second case the loss due to self-induction for the same length of cable was .0212 volt. From these experiments it would appear that when alternating currents are used, the out-going and returning cables should be in the same duct, which, indeed, is what theory would call for. To accomplish this in the best manner, a duplex cable is manufactured by the company in which both conductors are placed at a minimum distance apart.

We also find here full description of the Acheson electric light cable terminals, which allow of ready testing and for connecting the cable with pole line or lamps, and the Acheson cable protector, both of which are very fully described and illustrated. The Degenhart hard rubber terminal is also illustrated and described

One of the most valuable parts of the work is unquestionably that relating to the working directions for placing, splicing and laying electric cables. Here we find full directions for the laying of conduits either in the open box or cement-lined tube, the location of manholes and handholes, the operation of drawing cables into closed conduits and the tools required therefor, the laying of submarine cables, the stringing of aerial cables, house cabling and wiring, etc., and complete directions for making joints of all kinds and those specially adapted to the Waring cables. In short, the information given in this respect is so detailed and complete that, with a little experience, first-class work in this department ought to be accomplished with ease. To this are added very succinct rules and methods for testing electric cables, the locating of faults, grounds and crosses, etc., and the determination of insulation and capacity.

To all this valuable information there is added a chapter of general and electrical information showing the size of wires, comparison of wire gauges, electrical units, wiring formula and tables, and short rules for determining the sizes of conductors. Among these we find a very valuable table on the carrying capacity of cables, taking into account the heating effect and the various conditions in which they are used; and finally an electrical horse power table by which, when the ampere and voltage is known, the power can be read off at once.

The volume closes with the standard rules adopted by the New York Board of Fire Underwriters and various electrical statistics relating to central stations, isolated plants, electric railways, telephones, etc.

From the above it will be apparent that the work is one which reflects great credit upon the Standard Underground Cable Company and should be in the hands of every electric light, telegraph and telephone superintendent. We are not informed as to the size of the edition printed, but we make bold to say that a second edition will soon be in order.

Reports of Companies.

SECOND ANNUAL REPORT OF THE EDISON GENERAL ELECTRIC CO.

THE second annual report of Edison General Electric Co. was presented at the meeting of the company, held in this city on Monday, January 19, and in view of the circumstances of the past year and the immediate moment, is a most remarkable and encouraging document. It begins with a statement of the reorganization of the Edison industries, consummated in the centralization of a strong management and control, with a system of District agencies. For the success of this onerous and complicated work of reconstruction and amalgamation great credit is given in the report to Mr. Samuel Insull, second vice-president, and Mr. Joseph P. Ord, the comptroller. Reference is also made to the fact that it early became necessary to increase the manufacturing plant and working capital, in order to keep pace with the growth of the business, and to the fact that for the $2,000,000 then raised by the Sprague Co. the lenders are taking the stock of the General Co., whose capital stock was raised on Monday from $12,000,000 to $15,000,000. Of this sum, $1,000,000 remains in the treasury. The net earnings of the business were over 8 per cent. on the total stock, and this year the stock held under trust agreement by the Farmers' Loan and Trust Co. also becomes dividend bearing, beginning with the 2 per cent. payable February 1. The gross profits of the year, after deducting $266,071.27 set aside for depreciation of the plants of the several works, and $206,679.15 for general expenses, without including the royalties received by the Edison Electric Light Company, amounted to $1,896,177.06. From this sum various other amounts have been written off, as shown below. The 6½ per cent. deduction for depreciation was made on the entire plant, notwithstanding additions of $949,274.70 (or about 23¼ per cent., to the property accounts of the manufacturing plants) during the year, on which no appreciable depreciation could have taken place.

The General Company owns practically all of the capital stock of the Edison Electric Light Company, and therefore its profits should in point of fact be considered as part of the General Company's resources. From the statement of the Light Company, it appears that its net receipts during the fiscal year were $1,023,011.29 in cash and stocks and bonds of licensed local companies. In accordance with the policy which the Light Company has always pursued, this sum, together with stocks and bonds formerly acquired, is held in its treasury undistributed.

At the close of the previous fiscal year, there remained a balance of $679,401.48 to the credit of profit and loss on the General Company's books. The gross profits of the General Company during the year under review bring the total up to $2,782,257.69. From this there have been deducted $206,679.15 for general expenses; $100,000 charged off against patents; $614,711.41 charged off against cost of acquisition of stocks of sub-companies whose business has been consolidated into the company; and $665,314. for dividends distributed; after which there remains $1,195,553.13 carried into the new year to the credit of profit and loss. This sum does not include the business of the Light Company as above set forth.

The balance sheet of the General Company, dated October 31, shows that the quick assets, consisting of cash, bills receivable and accounts receivable, amount to $3,619,063.59, while the entire liabilities of the corporation, other than those to its stockholders, amount to only $2,647,828.41. Adding to the quick assets above stated, the sum of $4,272,903.63, which represents amounts expended on contracts in course of completion, and materials on hand and in process of manufacture, the active working capital of the company over and above its liabilities, appears to be about five and one-quarter millions of dollars.

All materials in stock and in process of manufacture are carried at net invoiced prices. The materials and expenditures on uncompleted work in progress are carried on the books at cost, and without any allowance for profits. This should be kept in mind in considering the value of the total of $4,272,903.68 above referred to.

Some condensed figures are also given in the report as to the magnitude of this united industry now bearing the name of Mr. Edison, with whom it is stated, by the way, that a new contract for experiments and inventions has been entered into. The company now has 6,000 employees on its pay rolls, and the transactions of the past year aggregated $10,000,000, while the current year opened with orders enough on hand to run the full force for a period of six months. In the special field of light and power from large central stations, a great development is taking place. In New York City a station, with a maximum capacity of 200,000 lights, the largest in this country, is being erected by the local company, and new stations of large capacity are going up in Brooklyn, Chicago, Milwaukee and Cincinnati. The local Edison Companies obtain their entire electrical plant and additions thereto, including apparatus and fixtures of every kind, from the works; and every new station therefore results in a large, new and ever-growing business. According to the official record, there were in operation on November 1, 1890, within the territory of the United States and the Dominion of Canada, large and small Edison stations representing an aggregate capacity of 1,371,000 lamps. In the Railway Department there was also greatly increased activity. The Sprague car motors sold in 1889-90 represent an aggregate of 27,679 horse-power, and the generators (dynamos for traction current) 22,836 horse-power, as compared with motors of 10,680 horse-power and generators of 7,665 horse-power in 1888-89.

There was expended during the year a total of $949,274.70 for new buildings, new machinery and other additions to the permanent plants. Of this amount $777,752.64 was invested in the works at Schenectady, and includes the cost of buildings and a portion of machinery for the manufacture of Siemens & Halske's patent underground cables from which large profits are expected. The new investments have more than doubled the capacity of the Schenectady works, and the number of employees was increased from 1,700 to 2,900, while the total product manufactured and sold shows an increase of 117 per cent. over the preceding year.

The enlargement of the lamp works, at East Newark, N. J., called for an outlay of $100,000, which will increase their capacity from a daily output of 11,000 lamps to 25,000 lamps. "The reduction in the price of its lamps, which this company was able to make two months ago in consequence of economies in their manufacture, for which it is indebted to the ingenuity of Mr. Edison, has already more than doubled its orders." The sales of lamps increased 64 per cent. over the previous year. The number of employees rose from 379 to 605.

The business of the New York works, formerly known as Bergmann & Co., increased 31 per cent. and the employees from 704 to 895. The growth of the Canadian business has made it necessary to abandon the shop at Sherbrook, P. Q., for new and larger works now being erected at Peterborough, P. O. The present force of 204 men will then be transferred from Sherbrook and largely increased.

It will be remembered that during the past year, the company created no small sensation by its reductions in the price of apparatus. There has been considerable curiosity to see whether the policy would be maintained. The report says on this subject: "It will not be out of place to mention in this connection that, as the best means of enlarging its business and meeting competition, the management of the company is steadily pursuing the policy of reducing the cost to customers while improving the standard of its products. In this endeavor the management is constantly seconded by the unceasing activity of Mr. Edison, and by the intelligence, skill and experience of a number of its officers and employees. The difference between the present manufacturing methods at our works and those of a few years ago, shows how great is the progress that has been made. A striking illustration is the reduction in the cost of our incandescent lamp."

The following were the trustees elected at the meeting, the name in italic being the only new one: C. H. Coster, T. A. Edison, *J. B. Williams* (vice-president, Northern Pacific R. R,), J. H. Herrick, Samuel Insull, Edward H. Johnson, A. Marcus, Carl Schurz, F. S. Smithers, H. Villard and J. Hood Wright. The executive officers are: President, H. Villard; vice-president, J. H. Herrick; second vice-president, S. Insull; secretary, A. Marcus; treasurer and assistant secretary, F. S. Hastings; assistant treasurer, A. S. Beves; comptroller, J. P. Ord.

AMAGANSETT TEL. & TEL. CO.

The annual meeting of the Amagansett Telegraph and Telephone Co., recently held at Amagansett, was very enjoyable to shareholders, as some 20 per cent. was reported as the dividend for this the first year's earnings. The following directors were elected: Benjamin H. Barnes, George C. Hand, J. Mason Schellanger, Capt. Joshua H. Edwards and William C. Cartwright.

AMERICAN BELL TELEPHONE CO.

The Bell telephone directors at their meeting in Boston on January 14, authorized the issue of $2,500,000 new stock April 1. This would give one new share for five outstanding, and will increase the capital stock to $15,000,000. A special meeting of stockholders will be called for Jan. 27, to act on the recommendation of the directors for an issue of new stock.

CHANGE OF OFFICERS OF THE COMMERCIAL CABLE COMPANY.

Mr. George G. Ward has been elected vice-president of the Commercial Cable Company, in place of Mr. Hector de Castro, resigned. Mr. Ward now occupies the dual position of vice-president and general manager. Mr. Chas. R. Hosmer, the well known and able manager of the Canadian Pacific Telegraphs, has also been elected a vice-president of the company. Mr. J. O. Stevens is now secretary and Mr. Albert Beck assistant secretary of the company.

EDISON ILLUMINATING CO., OF NEW YORK.

The Edison Electric Illuminating Company, of New York, in a statement to the New York Stock Exchange in connection with the application to list $1,000,000 additional capital stock, which was granted by the Governing Committee, makes the following comparative statement of earnings:

Years.	1888.	1889.	1890.
Gross	$226,301	$327,678	$488,595
Op. exp. and taxes	110,066	203.647	259.517
Net	$116,235	$124,031	$229,078

These earnings do not include any revenue from the large station on Pearl and Duane streets, now in course of erection, or from any considerable part of the additions and extensions recently made to the company's system throughout the city.

AFFAIRS OF THE WESTINGHOUSE CO.

A dispatch from Pittsburgh, Pa., of Jan. 15, says: The announcement this morning that the Advisory Board appointed by bankers and business men of this city to look into the affairs of the Westinghouse interests with a view of loaning the various concerns in need of assistance $500,000 to carry them through their present financial difficulties had returned the checks, notifying the subscribers that it would not be advisable to use any of the fund, occasioned no surprise, as the action had been expected for several days.

Two suits have been entered against the Westinghouse Electric Co. for small amounts. One was by the Keystone Bank, of Erie, Pa., for $2,000, and the other by Park Brothers & Co., steel manufacturers of this city, for $800.

A HOPEFUL VIEW OF THE WESTINGHOUSE TROUBLES.

Thirty creditors were present at the meeting of the creditors of the Westinghouse Electric Company on Jan. 17, at Pittsburgh. This is about one-fourth of the number. W. B. McLean presided, and as a result of the creditors' committee examination it was announced that the Pittsburgh creditors represented $147,500, and the outside creditors $300,000. Vice-President Bannister stated the company was doing well, and would soon be on a paying basis.

A telegram from a Chicago creditor representing $2,500 was received saying he would take it all in preferred stock. It was stated that the committee's examination of the books up to July 15 showed a daily business average for the last quarter of $15,000. Mr. Bannister said that, with proper management, the company would be worth $600,000 in annual profits to the creditors.

A proposition for creditors to accept preferred stock, instead of cash, was read, the signatures to be binding if 60.000 shares at $50 par value, or $3,000,000 worth, were disposed of.

Mr. Westinghouse was present, but was represented by H McL. Harding, who is in charge of the railroad department. He explained the situation from Mr. Westinghouse's standpoint, and said that lately they had cut down expenses to the extent of $600,000 a year. Not all of the creditors present were then prepared to sign, but those who did so took $65,000 of the preferred stock, and $25,000 more was promised.

Mr. Westinghouse was seen, and said that his efforts in New York to place preferred stock had been very satisfactory, and the stock taken there and at Pittsburgh had put a most favorable aspect upon the situation. He said he had there secured a subscription for four thousand shares by one interest, that he could answer for another four thousand, and that negotiations there were well advanced for placing twelve thousand five hundred shares more.

He also thought that under the present condition of things there was no reason why the retirement of the Advisory Board should have more than a momentary effect. He returned to New York on Sunday night.

THE UNITED ELECTRIC TRACTION CO.

The United Electric Traction Co., at 115 Broadway, has been levied on by the sheriff, on attachments aggregating $1,600 and a judgment for $804. The company is said to have been asking extra time on maturing obligations recently, and the total amount of unsecured indebtedness is said to be $150,000, while it is understood to have large assets. Leo Daft has brought suit against the company, the Daft Electric Light Co. and others to recover $50,000, and to set aside a contract relating to the exchange of stock of the Daft Company for that of the United Electric Traction Co., and to recover property of the Daft Company from the United Company. This suit may be discontinued.

It is declared by the officers of the United Company that its financial condition is being substantially strengthened.

The United Electric Traction Co. was incorporated in March, 1890, in New Jersey, with an authorized capital stock of $7,000,000 of which $5,000,000 was common stock. A large part of the latter was issued for the stock of the Daft Electric Light Co. and the Electric Power Co., of New York, and the right to use patents on storage batteries of the Julien Electric Co., the Julien Electric Traction Co. and the Brush storage battery. It assumed debts of the Daft Co. and of the Electric Power Co. amounting, it is said, to $400,000, and guaranteed $100,000 bonds of the Julien Electric Traction Co. It was said to have received from the Daft Co. tangible property worth $1,000,000, not including patents.

The company has been mainly developed by R. L. Belknap, ex-treasurer of the Northern Pacific Railroad, and Dr. John C. Barron. Mr. Belknap was its president until December last, when he was succeeded by J. Edward Ackley. In the same month the company gave a chattel mortgage of $700,000 to the Mercantile Trust Company to secure bonds.

STOCKS AND BONDS.

Wilson, N. C.—The town has issued $75,000 worth of bonds, $25.000 of which are for the erection of an electric light plant. G. D. Green, mayor, can give information.

Knoxville, Tenn.—The Knoxville Schuyler Electric Light Co. has issued $20,000 worth of bonds for the purpose of enlarging its electric light plant.

Hyde Park, Mass.—The Hyde Park (Mass.) Electric Light and Power Co. has placed on record in the town clerk's office a mortgage to the International Trust Co., of Boston, of all their property, both real and personal, to secure the payment of gold bearing bonds to the amount of $75,000, to be run 30 years at 5 per cent. interest. It is said to be the largest mortgage on local property ever recorded in that town. The local plant, it is said, has passed into new ownership, capitalized at $100,000.

ELECTIONS.

Bucyrus, O.—The Bucyrus Gas and Electric Light Company, at their annual meeting elected J. B. Gormly, W. C. Lemert, C. W. Fisher, G. C. Gormly and F. P. Kaler directors. This is the exact roster for the past year, and the organization will no doubt remain the same.

Newport, O.—The Suburban Electric Heat and Power Company has elected the following directors for the ensuing year:—H. M. Healy, Paris C. Brown, Jos. Feth, John P. Newman, A. M. Worthington, Harry Buchanan, Jr., and Chas. J. Helm.

Society and Club Notes.

BOSTON ELECTRIC CLUB DINNER.

The first dinner of the Boston Electric Club under the new administration was held on Friday evening at Young's Hotel, Boston, at which about 42 members were present. In the absence of Capt. Griffin, who was unfortunately detained by sickness in his family, Mr. C. J. H. Woodbury, one of the vice-presidents, presided, and after dinner introduced the various speakers. Speeches were made by Messrs. H. B. Cram, Col. Ransom, R. F. Ross, G. W. Mansfield, Dr. Austin, W. D. Warner, W. J. Denver, Mr. Thos. Goodrich, vice-president of the Niagara Insurance Co., of New York, and Mr. W. N. Colham, of London (who was a guest of Mr. Mansfield), and a member of the Civil and Mechanical Engineers' Society. Mr. Colham spoke particularly of his trip through the United States, and described in some detail the use of electricity in the operation of the underground railway in London. Some suggestions as to the future conduct of the club were made, Mr. Mansfield suggesting that the club be made a sort of hotel instead of an exclusive club. A most enjoyable evening was spent, and hopes were entertained that these entertainments would be held regularly every month.

Mr. F. L. Pope lectures before the Electric Club on Thursday evening on electric railways.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JAN. 13, 1891.

Alarms and Signals :—

Electrical Sporting-Indicator, S. D. Mott, 444,452. Filed June 19, 1890.

A signaling apparatus and electrical circuits to indicate visually at a distance the varying conditions of any sporting event, such as a ball game, a horse race, or the like. A number of indicators, at different points, may be connected upon a single circuit and operated from a given point, as from the grounds or track where the event is in progress.

Electrical Sporting-Indicator, S. D. Mott, 444,453. Filed June 19, 1890.

Development and amplification of No. 444,452 above.

Racing-Indicator, S. D. Mott, 444,454. Filed Aug. 7, 1890.

Special adaptation of the inventor's system to indicating at any desired point the movements of horses upon a race-track.

Clocks :—

Independent Electric Clock, E. G. Hammer, 444,433. Filed May 24, 1890.

An electro-magnetic apparatus is employed to wind the spring at intervals, and also to perform the mechanical work of advancing the hands or other indicating devices of the clock upon the dial to denote the time. A circuit-closer, operated by the escapement, admits current to the electro-magnet once each minute or at other predetermined intervals.

Electric Hand Setting Mechanism for Clocks, W. W. Bradley and W. N. Packer, 444,482. Filed March 28, 1890.

Claim 1 follows:

The combination, with a synchronizing-clock, of a magnet or a pair of magnets which when charged will first set the seconds-hand and then set the hour and minute hands.

Conductors, Conduits and Insulators :—

Conduit for Electric Wires, A. P. Wright, 444,477. Filed April 18, 1890.

A conduit for interior wiring. It consists of a number of short tubes having the inner diameter enlarged at the ends, each independent of the other and connected end to end by flexible tubing.

Conduit-Inspector, J. L. Blackwell, 444,687. Filed Aug. 9, 1888.

An apparatus for facilitating the examination of the interior of underground conduits of electric railways. The inspecting device adapted to be carried along through the conduit by a projection extending through the slot, includes an electric lamp and a mirror suitably arranged to illuminate the interior and disclose its condition.

Distribution :—

Electric Indicator, J. Hopkinson, 444,552. Filed Feb. 23, 1889.

Consists of elements and combinations of apparatus for carrying out the method covered in Patent No. 444,553 below.

Method of Controlling Currents upon Electric Circuits, J. Hopkinson, 444,553. Filed Feb. 23, 1889.

A method for determining the variations of potential, at a given point in a system of distribution, whereby the varying drop or loss of potential may be readily compensated for all times; specially applicable to constant-potential distribution. Employs an electro-magnetic indicator, wound with two opposing coils, one of high resistance connected across the terminals of the source of electricity, and the other of low resistance so connected as to be traversed by all or a determinate portion of the current flowing through the translating devices. The differential action of the apparatus may be made to indicate the relation between the difference of potential required at the terminals of the source and the amount of current flowing to the work circuit.

Dynamos and Motors :—

Electric Motor, W. A. Anthony, 444,416. Filed May 14, 1890.

Relates to the windings of field magnets; and consists in winding a field magnet with an ordinary shunt-wire for its magnetization at all times when the motor is running, and in the additional winding upon the same magnet of a separate wire, the function of which is to interpose a large but gradually decreasing resistance between the main line conductor and the armature when the current is first turned on, and also to supplement the magnetic effect of the shunt-wire when the motor is started and until the motor has attained its full speed, when the resistance wire is cut out.

Dynamo-Electric Machinery, J. B. Entz, 444,486. Filed July 10, 1890.

A design and arrangement of field magnets and pole-pieces. The field magnet consists of a single coil of wire wound upon an elliptically-shaped coil; an extended forked pole-piece passes from end of the coil around the sides of the magnet to the other end forming two poles of like polarity, while a shorter forked pole-piece attached to the other end of the coil forms two poles alternating in position with the two first named.

Regulator for Dynamo-Electric Machines, R. E. Ball, 444,587. Filed Feb. 26, 1860.

Dispenses with mechanism such as is usually employed for the automatic shifting of the brushes upon the commutator, by changing the position and shape of the yoke carrying the brush holders, making it of magnetic metal, as iron, and so adapting its shape and position that it shall automatically shift the brushes for regulation under the influence of the variation in the number of magnetic lines of force passing through it from the field magnets.

Brush for Dynamos, A. S. Cook, 444,794. Filed Mar. 28, 1890.

Claim follows:

A carbon brush for dynamos and motors, the pores of which are filled with oil.

Ignition.

Electric Gas-Lighter, T. W. Lane, 444,706. Filed June 18, 1889.

Improvement in the class of lighters known as "automatics." Claim 1 follows:

In an automatic electric gas-burner, a rotary gas-cock attached to a ratchet-wheel, and a pawl so connected with or operated by the armature as to admit the gas at its complete depression and thereafterward admit of a series of partial vibrations of the armature without withdrawing the pawl entirely from the tooth of the ratchet during pressure on the button.

Lamps and Appurtenances :—

Electric-Light Support, A. Dawes, 444,424. Filed Jan. 29, 1890.

An adjustable-arm support for incandescent lamps.

Electric-Lamp Bracket, T. C. Smith, 444,466. Filed May 19, 1980.

A design and construction of a bracket for incandescent lamps, especially for street lamps.

Carbon for Arc Lights, B. B. Ward, 444,471. Filed April 4, 1890.

A carbon designed to obviate hissing and sputtering. The carbon has a longitudinal bore or passage, the walls of which are coated with a thin film of a silicate—as for example, silicate of soda.

Electric-Arc Lamp, B. B. Ward, 444,472. Filed April 11, 1890.

Relates particularly to automatic safety devices for arc lamps and designed to prevent injury in case of abnormal variations in the length of arc; provides means by which the current may be shunted around the lamp while at the same time the coils of the regulating derived-circuit magnet may be protected from injury.

Electric-Arc Lamp, B. B. Ward, 444,473. Filed April 11, 1890.

Relates to the disposition of parts, such as lamp-hood, artificial resistances, etc.

Claim one follows:

The combination, with an electric-arc lamp, of a lamp hood, a chimney for the arc lamp, and an artificial resistance-frame mounted in the chimney of the hood independently of the lamp and provided with a vertical passage or opening to receive the lamp-chimney.

Incandescent-Lamp Socket, G. R. Lean, 444,567. Filed March 27, 1890.

Design and construction for cheapness and efficiency. Block and holder engage by a bayonet joint.

Leading-in-Wire for Incandescent Electric Lamps, T. A. Edison, 444,530. Filed Sept. 15, 1890.

Intended to economize the amount of platinum employed for leading-in-wires. The leading-in-wires are made in sections, one section being of platinum or other metal whose coefficient of expansion is substantially the same as that of glass; the platinum or other similar metal is included in that portion of the leading-in-wire which is sealed into the glass.

Claim 1 follows:

An incandescent electric lamp having leading-in-wires composed of sections of different metals, one of which sections is of a metal whose coefficient of expansion is substantially the same as that of glass, the other of a metal which has a different coefficient of expansion, and both of said sections being sealed into the glass.

Measurement :—

Phase-Indicator for Alternating Electric Currents, C. S. Bradley, 444,791. Filed June 23, 1890.

Claim 1 follows:

An indicator for showing a difference of phase in two or more alternating currents, comprising a synchronous electric motor operated by one of said currents and a magnetic device controlled by another of said currents, said device co-operating with a rotary element driven by the synchronous motor and adapted to be angularly displaced when corresponding phases of the two alternating currents are not simultaneous.

Potenital-Indicator, E. Weston, 444,803. Filed June 5, 1890.

An instrument for showing variations in potential of a current maintained on a circuit or for indicating electrical pressure in volts. Consists, substantially of two coils connected in circuit and having their longitudinal axes in prolongation, one of the coils being both rotary on its axis and movable with respect to the other coil, near which it is placed in inductive proximity, and a means for indicating the extent of rotation of the movable coil; a translucent scale plate is employed for the indication.

Electrical Measuring Instrument, E. Weston, 444,804. Filed June 11, 1890.

An instrument for the same purpose as that of No. 444,803. above, and similar in principle, but employing two fixed coils and a movable coil.

Electric Measuring Instrument, E. Weston, 444,805. Filed Oct. 18, 1888.

For measuring the electromotive force of electric currents in volts. Consists of an apparatus in which an electrical conductor in loop form is supported in the field of force of a magnet and is free to move bodily in such field under the influence of the current traversing the loop. The motion of the conductor is opposed and equilibrated by a spring, the extent of its movement being shown upon a scale.

Medical and Surgical :—

Electric Magnetic Massage-Kneader, D. Lichtenstadt and C. Lichtenstadt, 444,597. Filed Dec. 8, 1890.

Consists in a kneader provided with electric elements, which are adapted to be rolled over the surface to be treated, and a magnetic bar supporting such elements.

Electric Appliance for Trusses, A. Owen, 444,599. Filed Oct. 11, 1890.

An insulating truss-pad is provided with an adjustable and movable metal cap having means for connecting with it a conductor.

Miscellaneous :—

Rheostatic Switch, J. H. Lehman, 444,707. Filed Mar. 8, 1890.

Claim 1 follows:

In an electric switch, a resistance device consisting of blocks of plumbago and potters' clay separated by discs of platinum, the discs being connected with separate contact plates, and standards supporting the resistance device.

Voltaic Insole, M. E. Thomas, 443,735. Filed Nov. 6, 1890.

Insole has electrodes suitably arranged and connected with each other, the perspiration from the foot being depended upon to excite electric currents.

Lightning Arrester, E. Thomson, 444.678. Filed March 17, 1890.

Consists, broadly, in constructing a lightning arrester or discharger with a succession of striking spaces in series and in making the sum of the striking spaces several times greater than the space which would be given to an ordinary lightning arrester, or between the plates of a single break lightning-arrester. The inventor prefers that the metal pieces interposed between each successive break should have some capacity for static charge, as this facilitates the successive breaking down of the disruptive spaces by a lightning discharge or sudden static effect.

Electric Elevator, N. P. Otis and R. G. Smith, 444,640. Filed Jan. 31, 1890.

Claim 1 follows:

The combination, with the electro-motor of an elevator, of a current-controlling device constructed to both reverse and vary the current and provided with a switch, means for automatically turning the switch to its normal position with the current cut-off, and means for operating said switch from the cage to carry it from its normal position in either direction.

Railways and Appliances :—

Electric Trolley, C. A. Lieb, 444.447. Filed Nov. 28, 1890.

For electric railways. The groove of the trolley is provided with a yielding or elastic surface supported upon a spring or springs or equivalents.

Electric-Car Controlling Device, E. M. Bentley, 444,479. Filed July 10, 1885.

Comprises a speed changing mechanism, by which the ratio of speed between the armature and driven axles may be changed, and a regulator for the motor and brake for the car which are controlled by the same operating lever which brings the variable gear into and out of action.

Electric Railway Car, E. M. Bentley, 444,480. Filed Sep. 8, 1888.

Includes a regulating device for the motor and a brake for the vehicle, controlled by a common actuating device, so that they shall be operated simultaneously.

Electric-Locoomtive, M. Waddell & J. B. Entz, 444,512. Filed May 20, 1890.

Relates to the manner of mounting an electric motor upon a car truck, with a view of relieving excessive strain at the time of starting or whenever the motor shaft tends to a sudden relative movement; the field magnet structure and frame is mounted in such a manner that it is free to rotate slightly on its axis when under severe strain, being loosely mounted upon an axis and connected to a strong spring with a rigid portion of the truck.

Electric-Railway Car, L. A. McCarthy, 444,589. Filed Sept. 3, 1890.

Relates to the method of transmitting motion from the armature shaft to the car axle. Driving rods, upon cams mounted upon the ends of the armature shaft are used in conjunction with friction pulleys, in place of the gearing usually employed. A single motor hung midway of the length of the car is thus joined to both axles.

Current-Collecting Device for Electric Railways, R. M. Hunter, 444,566. Filed Aug. 12, 1890.

The trolley is mounted at the end of a rearwardly-extending part jointed to the upper end of the trolley pole so as to have freedom of lateral motion, and extending parallel with the trolley wire.

Automatic Signal for Railway-Crossings, A. W. Hall, 444,700. Filed July 26, 1890.

An apparatus for indicating to the trainmen whether crossing gates are open or closed.

Electric Railway, E. M. Bentley, 444,740. Filed July 10, 1885.

A turn-table or transfer-table for electric railways, applicable to roads operated by underground conductors.

Telephones and Appliances:—

Device for Inserting Branch Lines on Mechanical-Telephone Lines, G. F. Shaver, 444,461. Filed March 22, 1890.

For inserting branch wires at right angles with the main trunk line of a mechanical telephone line so that speech may be transmitted from one to the other without loss of power or impairment of articulation.

Mechanical-Telephone Exchange, G. F. Shaver, 444,462. Filed May 1, 1890.

Details of mountings or supports for mechanical telephones.

Mechanical-Telephone Exchange, G. F. Shaver, 444,463. Filed May 6, 1890.

A number of diaphrams and connected line wires are mounted upon and combined with a common sounding board.

Molecular Sound Resonator, G. F. Shaver, 444,464. Filed May 12, 1890.

Claim 2 follows:

The combination of two metallic resonators connected one with the other by means of a jointless metallic conductor.

Magneto-Bell, W. R. Patterson, 444,600. Filed May 27, 1890.

Relates to the class of electric bells in which the mechanism is placed within the box and the gongs and hammer outside, such as are used in the telephone service. Consists generally of mounting the gongs upon adjustable plates pivoted to the metallic frame which supports the magnet, the construction being such that the adjustment of these plates would be unaffected by changes that may take place in the wooden boxes.

Telephone Enunciator or Indicator, G. R. Lawrence, 444,780. Filed April 10, 1890.

An electro-magnetic and mechanical apparatus including a clock dial, designed to indicate automatically to a person sending a telephone message, in the absence of the person to whom the message is sent, the exact time the person called may be reached to receive the message, and for other similar purposes.

Legal Notes.

MONTREAL TELEGRAPH CO. vs. GREAT NORTH-WESTERN TELEGRAPH CO.

The directors of the Montreal Telegraph Company have presented their annual report. It chiefly refers to an action entered against the company by the Great North-Western Telegraph Co., on January 31, in the Superior Court, for a reduction in the rate of dividend payable under the conditions made in the agreement of Aug. 11, 1881, a reduction from 8 to 6 per cent. and also for another demand filed on September 26, 1889, for a further reduction of 2 per cent. with the exception of costs for proof. Both these actions had been dismissed. The G. N. W. had appealed to the Court of Queen's Bench, with the result that the ruling of the Superior Court had been sustained. The G. N. W. is now appealing to the Supreme Court of Canada against the judgment rendered against it. The balance of quarterly instalments paid since 1889 by the G. N. W. is deposited in the Canadian Bank of Commerce, awaiting the result of the suit. The amount of these balances are $70,000 with four per cent. interest.

A STORAGE BATTERY SUIT OF THE FORT WAYNE CO.

The Fort Wayne Jenney Electric Light Co. for the use and benefit of the M. W. Simons Electric Light Co. has begun suit for $20,000 damages against Abner Crossman, Samuel Heavenrich, Simon Heavenrich, Louis Mendelssohn, Hugo Hill, Isaac Mendelssohn and Sigmond Simon. It is claimed that the plaintiff corporation on June 27, 1889, contracted with the Pumpelly Storage Battery Co., of which the defendants were stockholders, to manufacture, at Plymouth, Ind., storage batteries until June 30, 1892. The Pumpelly Co. were to pay 20 per cent. above manufacturers' cost for the first 50,000 cells and 15 per cent. for all over that number. If the orders were less than $10,000 the Jenney Co. was to be paid for the expense of the plant. Isaac Mendelssohn did not sign the contract. The Jenney Co. sue for an alleged violation of the contract for the benefit of the M. W. Simons Electric Co., to which the contract has been assigned.

THE POWERS OF TOWN CORPORATIONS IN MASSACHUSETTS.

The full bench of the Supreme Court has sent down a decision holding, in the case of Willard Spaulding against the town of Peabody, that the committee of the town will be restrained from proceeding to establish and construct an electric light plant for the use of the town. The court says: "We assume that the Legislature by statute can confer upon towns authority to construct and maintain works for the manufacture and distribution of electricity to be used by the towns and their inhabitants for illuminating purposes. The question now presented is whether the existing statutes confer any such authority, either for the purpose of lighting the streets of towns or for this and the additional purpose of furnishing light to their inhabitants at reasonable rates. Such authority is not within any of the customary powers which towns from very early times have exercised, and must be derived, if it exists, from the statutes relating to towns."

ALUMINUM. — COWLES CO. vs. THE PITTSBURGH REDUCTION CO.

In the United States Circuit Court at Pittsburgh, on Jan. 17, Attorney M. W. Woodward filed papers in a suit for infringement in behalf of the Cowles Electric Smelting and Aluminum Company, of Lockport, N. Y., against the Pittsburgh Reduction Co. Infringement is claimed on four patents, described as "improvements in electric processes of smelting ore for the production of alloys, bronzes, and metallic compounds"; "an electric furnace and method of operating the same," and two improvements on the furnace. The Cowles Company claims that these patents, taken out in 1885 by Eugene and A. H. Cowles, are being used and operated by the Pittsburgh Reduction Company for the purpose of making aluminum and alloys.

G. H. Clapp, of the Pittsburgh Reduction Company, said: "Some time ago the Cowles people wanted to effect a consolidation with our company and build a big factory at Niagara. We had no use for their company, and we told them so. Our own patents are much more valuable and better adapted to our use than theirs. The process we use is not an infringement on the Cowles patent. They make only alloy; we make pure aluminum. They depend upon the heat produced by electricity, while we depend upon the action of the electric current."

RUTLAND, VT.—Suit has been entered against the Marble City Electric Light and Power Co., of Rutland, Vt., by the Brush Electric Co., of Cleveland, O., for infringement on its double carbon arc lamp patent.

TOLEDO, O.—Evidence has lately been taken at Toledo in the suit of the Brush Electric Co. against the Western Electric Co., for infringement of the double carbon arc lamp patent.

College Notes.

LECTURES AT COLUMBIA COLLEGE.

The course of evening electrical lectures at Columbia College has begun with every prospect of success. The popularity of the course is shown by the fact that there have been 20 applicants already more than the capacity of the room. There are 92 seats and 92 season tickets were sold. This is quite remarkable in view of the fact that there has been no advertising of the course, and that attention has been drawn to it only by brief notices in the newspapers.

Appointments, Etc.

MR. D. A. PALMER, of Chicago, has been engaged to manage the telephone system in Duluth.

DR. H. W. WHITMORE, has been elected secretary of the Citizens' Electric Light Co., of Akron, O., in place of S. E. Phinney.

MR. J. PARLETT of the Urbana telephone exchange, has resigned, to become night manager for the W. U. at Dayton. He will be succeeded as manager at Urbana by Mr. H. Huffman, of Columbus, on January 15.

MR. P. A. UNDERWOOD, of the Nantucket, Mass., Electric Light Co., has left the Island and severed his connection as superintendent. He is succeeded by Mr. John R. Bacon, of the Steamboat Co.

MR. J. R. MCKEE, son-in-law of President Harrison, has, it is stated, formed a business connection with the Thomson-Houston Electric Co.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

> *"The advertisement should be characterized by all the freshness and attractiveness of a personal interview."*

ALMOND'S FLEXIBLE METAL TUBING FOR BRACKETS AND ELECTROLIERS.

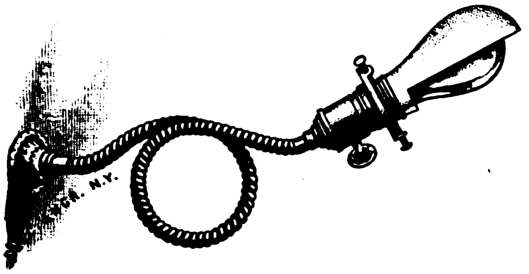

FIG 5.

It might, on first thought, be considered impossible to make a metallic tube which would be quite flexible and which could be made to convey gases and liquids under considerable pressure, as well as electric wires. This has, however, been successfully accomplished by Mr. J. R. Almond, of No. 83 Washington street, Brooklyn. The manner in which the tube is formed will be apparent from the accompanying engravings. When a tube is formed by coiling a wire around a mandrel (Fig. 1), the convolutions may be made to press upon each other with considerable force, and the joint formed at the point of contact of the individual convolutions will be tight in proportion to the amount of pressure exerted. If such a tube be bent, the joints will be broken all around the coils except at one point, and therefore, when bent, it is useless for conveying liquids or gases. But if, between the convolutions of the spring there is interposed a triangular shaped wire, as shown in Fig. 1, the convolutions of the triangular coil adjust themselves to the spaces between the round coils, as shown in Fig. 2. The triangular wire is pressed between the coils of the round wire, during the process of constructing the tube, with sufficient force to spread them apart, so that the contact surfaces are at all times under pressure. The triangular wire serves two purposes. One is to spread the coils apart, so that the pressure will be exerted on the contact surfaces; the other, to fill the irregularly shaped spaces between the coils of round wire, adjusting itself to the changing form of the spaces due to any given flexion. This pressure brings into play the element of friction to such an extent as partly to destroy the flexibility of the tube, which, when bent, will retain the form given to it. This was an unlooked for and unexpected quality. As the primary object was to obtain a flexible tube, trials were made with wire having a more obtuse angle, such as is shown by Fig. 3. This gave better results, as a more perfect joint was produced, with less tension of the inner coil, and the friction became correspondingly less, the result being a tight tube with sufficient flexibility. Fig. 4 shows the shape of the seats into which the round wires are forced by their tension.

FIG. 3.

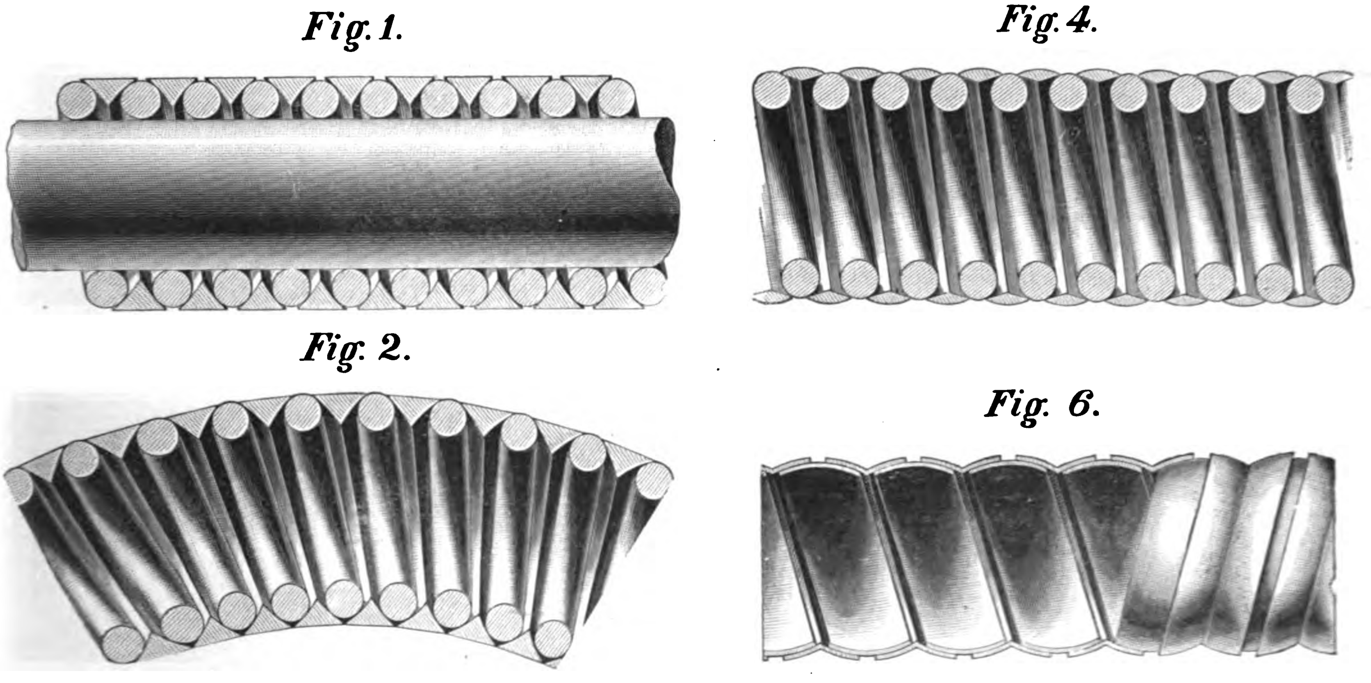

Fig. 1.

Fig. 2.

Fig. 4.

Fig. 6.

FIGS. 1, 2, 4 AND 6.—ALMOND'S FLEXIBLE METAL TUBING FOR BRACKETS AND ELECTROLIERS.

Our engraving, Fig. 5, shows the great adaptability of this ingenious flexible tube to bracket and chandelier work for electric lighting purposes, both for plain and combination fixtures, as the tube is both gas and water tight. The tube shown has been subjected to a steam pressure of 75 pounds per sq. inch without exhibiting leakage, and can be bent to a circle 2 inches in diameter, the tubing having a bore of $\frac{5}{16}$ inch.

For electric work alone, where no pressure is required, Mr. Almond has designed the tube shown in Fig. 6, which is made of sheet metal and can be made as large as 2 inches in diameter.

THE RIKER ELECTRIC MOTOR CO.

The Riker Electric Motor Co. factory is a very busy place at present. They have been making extensive alterations, adding to their machinery, and increasing their force of help preparatory to a large demand for their new types of multipolar and bipolar slow speeded motors. They are now prepared to fill orders on all sizes of the bipolar, which is made up to 4 h. p., and on their multipolar machinery to 25 h. p. In addition to their regular stationary machines, they have a most presentable and efficient design for direct acting machinery and are at present mounting a large number on ventilating fans of different makes from 24″ in diam. to 60″.

Mr. Riker is to give his attention soon, he says, to infringers of his patents, and it would be well for purchasers of dynamos and motors of other makes to investigate the matter beforehand. It is well know that Mr. Riker, young as he is, has been a pioneer in much of this work, and he believes that his patents and claims will hold.

SHULTZ BELTING CO.—The Shultz Belting Co. have 8 of their woven leather belts in use on the Lindell Electric Railway Co. in St. Louis, each 70 feet long and 24 inches wide.

NEW DEPARTURE OF THE BALL ENGINE CO.

There seems to be a prospect that the well-known Ball engine, many of which are doing such good service in the East, will shortly be manufactured by a new company organized for that purpose in the vicinity of New York. We understand that a number of New York gentlemen have made arrangements with Mr. F. H. Ball, of Erie, Pa., the inventor of the engine, and having bought his patents, Mr. Ball will sever his connection with the Ball Engine Co., of Erie; and shortly take up his residence in the East, where he already has many friends among our leading mechanical engineers.

It is expected that the new company will be incorporated with ample capital, and that new shops will be erected possessing all recent mechanical improvements. The Ball Engine Co., of Erie, will continue as at present to manufacture the engine under Mr. Ball's shop rights, and with Mr. James McBrier as president, whose large lumber and other interests in the West have made his name familiar to business men in that section. The relations between the Erie and New York companies will be very cordial and intimate, since the latter will be largely interested in the stock of the former.

Prominently associated with Mr. Ball will be Mr. Thos. C. Wood, who for many years has been connected with the engine interests both in Erie, Pa., and in New York.

The new enterprise is the result of the increase in demand for the Ball engine, Mr. Ball's system of governing having proved so successful, and the Ball engine so reliable, especially for the electric light and street railway interests, that it is safe to assume for the new company a large and profitable business from the start.

ELECTRIC RAILWAY WORK AT AMSTERDAM, N. Y.

On Saturday, Dec. 20th, the Amsterdam and Rockton Electric Railway opened to the public the Maine and Division street line, just equipped, which had up to that time been operated by horses. The trial trip was a great event in the history of Amsterdam and excited much enthusiasm among the citizens. The Market street branch, an entirely new line, was opened January 16th, and its successful operation, comprising as it does, some of the steepest grades ever met with in street railway practice, is considered another triumph for the electric motor. The up grade on this line is continuous for about 2,000 feet, and for a short distance is as high as 12%.

The equipment has been in the hands of Woodbridge & Turner, electrical engineers, who have made it a model in the way of construction. With the completion of the Rockton branch, the road will comprise about four miles of track, operating five cars.

The track is of 48 lb. Johnson girder and 40 lb. T rail. Edison-Sprague motors are used, with the new Eickemeyer winding, mounted on Brill trucks; and special track brakes are provided for use on the heavy grades. The line work is a sample of neat, strong and durable construction.

The power plant is located temporarily in the old electric light station, but in the spring as soon as the weather permits, a new building will be erected to accommodate both the electric light and railway plants, these two companies being now consolidated.

CENTRAL ELECTRIC CO., CHICAGO.

The Central Electric Co. will shortly present to the public a very handsome and complete catalogue of electrical supplies. The page will be 7¼ inches x 11 inches, printed on heavy enameled book paper. It will be a fine sample of printing and bindery work, as well as an electrical encyclopedia. Each article will be described by a trade word, which will greatly facilitate ordering supplies, and save considerable expense when orders are sent by telegraph. The book will appear inside of 30 days.

The Central Electric Co. will shortly place upon the market a direct reading voltmeter and ammeter. It is claimed that this new instrument is as good as any that has been produced. It will be elegantly finished, as well as thoroughly standardized, and will be sold at a price so low that everyone connected with electrical work can afford to buy one.

Since the Central Electric Co. divided up their offices and appointed heads to the different departments of the business, they find that they can profitably assign one man to railroad supplies, and propose to vigorously push that department of the business in future. They already control some very valuable electric railroad specialties which will be placed upon the market with the accustomed vigor of this company.

THE LECLANCHE BATTERY CO.

The factory and office of this company have been removed to Nos. 111 to 117 East 131st street, in this city, where, with greatly increased space and facilities for manufacturing, they will be able to fill orders without delay, for their well-known and universally used battery.

CHAS. A. SCHIEREN & CO.

Mr. G. H. Fisher, formerly the secretary of the American Leather Link Belt Co., has become manager for Chas. A. Schieren & Co., manufacturers of the celebrated patent perforated electric belting, at 226 North Third street, Philadelphia, Pa.

THE MAYER MOTOR.

The Zucker & Levett Chemical Co., of 40 Murray street, New York, the well known manufacturers of chemicals and machinery for electro-plating and electro-typing purposes, have made arrangements to build the motor designed by Mr. Max Mayer and described in our issue of January 7th. The machine, which will be known as the Hercules, will be built in all sizes and for all circuits.

THE BUNDY WORKMAN'S AUTOMATIC TIME RECORDER.

In factories, shops and stores where a large number of people are employed and where the minutes lost individually aggregate many hours, it is necessary to keep strict account of the time at which employés begin and leave their work. The employment of a special time-keeper for this purpose, not only entails considerable expense, but is open to the objection that it gives rise to frequent disputes as to the accuracy of the time-keeper's record.

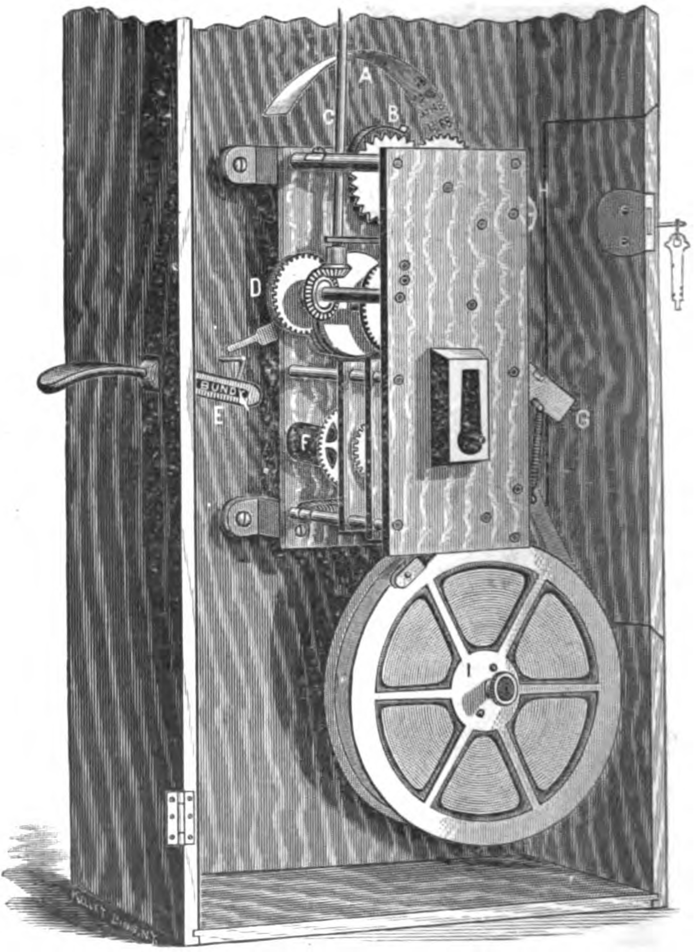

Fig. 1.—The Bundy Workman's Recorder.

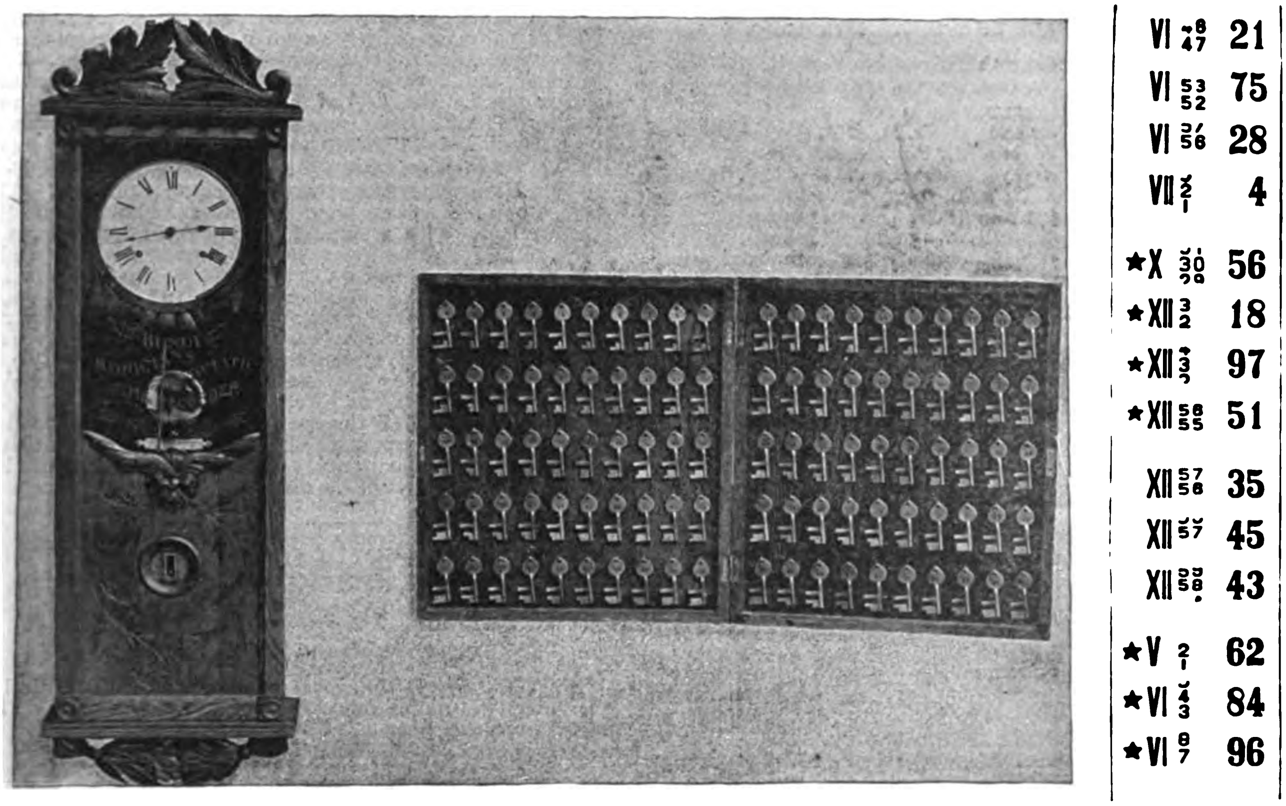
A system, therefore, which practically makes every man his own time-keeper will be admitted to be a valuable adjunct to every factory and workshop.

This has been completely provided for by the ingenious workman's automatic time recorder of the Bundy Manufacturing Co., of Binghamton, N. Y., an illustration of which is given in the engraving, Fig. 1.

Each workman is given a number, and when he goes to work he takes his key from the key board, inserts it in the keyhole of the recorder, turns it half way round, takes it out and passes in to his work. This action records upon the paper ribbon within the machine the number of his key and the exact time of day to the minute. If it is desired to register when going out, the workman holds down the lever on the outside of the recorder while registering, which prints a star in front of the record. Fig. 2 shows the working parts, the rod C connecting the minute wheel of the clock by a simple bevel gear to the minute type weeel. The hour wheel by means of a little pin is thrown ahead one number each revolution of the minute wheel; thus it will be readily seen that the time printed must correspond with the time shown by the clock.

The keys have two functions. One tongue trips the hammer, which is not released, however, until the other tongue, by means of step cams, geared to type wheels, has thrown the necessary number in front of the hammer, so that when the hammer falls it must print not only the time as shown by the clock, but the number of the key used. The paper, of course, is spaced with each blow of the hammer, and with every sixth blow of the hammer the ink ribbon moves ahead one notch, so the print is always fresh and clear. It is stated that 100 men can easily register inside of five minutes.

Fig. 3 illustrates a piece of the paper ribbon as it appears printed when removed from the recorder. From this slip it would appear that No. 21 registered at between 47 and 48 minutes past 6 o'clock; No. 75 at 6:53 o'clock; No. 28 at 6:56 o'clock, and No. 4 at 7:02 o'clock; No. 56 went out at 10:30 o'clock; No. 18 at between 2 and 3 minutes past 12 o'clock, and so on through each number as indicated. It will thus be seen that the time of each employé can be read off at a glance, and there is no chance for a mistake. The slips of paper can be removed daily, twice a day or weekly, and filed away, and the workman's time is practically in his own handwriting, but is entirely beyond his control. To prevent one man from registering for another, as each register is recorded a bell rings, so that a man registering twice could be easily detected by anyone in sight. The recorder also has a device by which the key after a partial turn is locked in and cannot be taken out until it registers, so that the excuse of an attempted register is out of the question. The apparatus is so simple that it is practically impossible to get out of order.



FIGS. 2 AND 3. BUNDY'S WORKMAN'S RECORDER.

THE CROWDUS CHEMICAL ELECTRIC CO., OF MEMPHIS, TENN.

This company has just been organized to manufacture a multipolar cell battery for electric lighting and power purposes not exceeding two horse power, and for all purposes where a powerful and constant battery is required. This cell has been designed by Mr. Walter A. Crowdus, and the solution employed contains no chromic acid, in consequence of which, no precipitates or crystals are formed. The elements employed are carbon and zinc, and the connections of both zinc and carbon are submerged in the body of the liquid, by which arrangement all corrosion is avoided. The battery having a surface of 12 inches, an output of 50 amperes is obtained and it is able to drive a fan at 1,600 revolutions per minute each working day without any attention, and at a cost of only ½ cent per hour. During this time the battery consumes one gallon of solution costing 15 cents a gallon. It is estimated that the cost of operating the battery, including everything, does not exceed 40 cents a week. The company expect to be ready shortly for business, and are so thoroughly convinced of the qualities of their cell that they will guarantee all their goods. For electric lighting they estimate that the cost will be less than two cents per hour for a 16 c. p. lamp.

HABIRSHAW WIRE IN THE WEST.

Among many testimonial letters in regard to Habirshaw wire, The Electrical Supply Co., of Chicago, lately received the following from The Rockford Electrical Manufacturing Co., Rockford, Ill:

Gentlemen:—In reply to your favor of the 7th inst.——say that we have been using Habirshaw wire under the most trying conditions for the past year, and have yet to hear the first complaint. We believe it to be fully equal, if not superior, to any wire on the market and shall continue to use it in preference to any other where the highest quality of insulation is required.

Yours very truly,
ROCKFORD ELECTRICAL MANF'G. CO.,
per GEO. A. MAYO, E. E.

MR. E. G. BERNARD.

Among the recent plants sold by E. G. Bernard, the well-known engineer and contractor of Hall Building, Troy, N. Y., are Gardner & Warren, knitting mill, Amsterdam, N. Y., 200 lights; Victor Knitting Mills, Cohoes, N. Y., 300 lights increase. This last plant makes Mr. Bernard's fifty-fourth knitting mill contract.

THE WIGHTMAN ELECTRIC MANUFACTURING CO.

The above company, of Scranton, Pa., has just issued a very neat and tasteful calendar for 1891. The engraving represents two big ocean "grey-hounds" racing, and on the bellying sail of the one in the lead is the name of the Wightman Co. We have submitted the calendar to our naval expert, who pronounces the drawing to be a fine piece of marine work to come from an inland town, and to be very creditable to the designer. The company are manufacturers of and dealers in electric machinery, and specially slow speed railway motors. L. R. Bacon is president of the company; Merle C. J. Wightman, vice president and electrician; H. Bergholtz, general manager; Horace E. Hand, secretary and treasurer.

MR. E. T. COPELAND.

Electrical and steam engineering circles have been very much interested in the announcement made recently in our columns to the effect that Mr. E. T. Copeland, so long associated with the New York Safety Steam Power Co. as its general agent and business manager, was about to make a new departure. During his twelve years of service in the above capacity, Mr. Copeland has seen, and assisted in promoting actively, the growth of the electric light and power industry; and at a time when the business was as much in need of steam engineering talent as of anything else, he bent all his energies with great success to the equipping of well-planned stations and isolated plants. He has now established himself as E. T. Copeland & Co., at 106 Liberty street and 111 Cedar street, where he will devote himself to steam engine and boiler work, &c., and in his new field of labor may count confidently on enhancing his reputation and increasing the number of his friends and customers. Mr. Copeland has already made arrangements for the manufacture and sale of desirable engines, which he will handle, and a little later we shall have fuller mention to make of his plans in their various details. As before, he will be prominent in the electric light and power field.

DENIAL OF SALE OF THE WENSTROM CO.

The following letter from the Wenstrom Consolidated Co., of Baltimore, dated Jan. 16, to their agents, tells its own story:

MESSRS. CHADBOURNE, HAZELTON & Co.,
General Agents Wenstrom Con's. D. & M. Co.,
416–420 Walnut St., Philadelphia, Pa.

Gentlemen:—Replying to your favor of the 15th inst., in which you state that rumors have come to you from various sources that the Wenstrom Co. has been bought out by other concerns, I beg to say that you may emphatically deny all such reports.

The Wenstrom Co., as you know, have just completed one of the finest electrical factories in the world, and being possessed of many valuable patents and having demonstrated the superiority of their generators and street car motors, are in a position to fill all orders promptly and believe that any combination which could be suggested, would be a hindrance rather than an assistance to them. You may assure your agents and customers that we are in an entirely independent condition, and are prepared to deliver goods promptly.

Truly yours,
THE WENSTROM CONSOLIDATED DYNAMO & MOTOR CO.
[Signed.] E. L. TUNIS, President.

ST. LOUIS TRADE NOTES.

THE ROSE ELECTRIC LIGHT SUPPLY CO., the well-known dealers in second hand electric light apparatus, are meeting with continued success in their special line of business. Among late sales may be mentioned:—50 arc light American machine and 40 lamps to the St. Louis Wire Mill Co.; 25 arc light Western Electric machine to Pawpaw, Mich.; 25 arc light Western Electric machine to the Tamarack Copper Mining Co. Dallas Bay, Mich.; two 35 arc light Ft. Wayne Jenney machines to the Greencastle Electric Light and Power Co., Greencastle, Ind.; 6 arc light Van Depoele machine to G. W. Farnsworth & Co., Fond DuLac, Wis.; 300 light U. S. incandescent machine to the Electrical Engineering and Supply Co., Elmira, N. Y.; 150 light incandescent machine to the Effingham, Ill., Electric Light Co.

THE SHULTZ BELTING CO. are crowded with orders for their famous rawhide and woven leather belting. They have just finished an order for eight 24 inch woven leather belts for the power station of the Lindell Railway. Their woven leather belting, which is a radical departure from the usual forms of link belting, in that wire rods are replaced by rawhide rods, is meeting with unqualified success wherever introduced.

THE ST. LOUIS ELECTRICAL SUPPLY CO., 403 North Eighth street, one of the oldest electrical supply houses in the city, report a most satisfactory increase in their business during the past year, with prospects for heavy trade during the coming year. W. L. Scott is president and treasurer.

THE EMERSON ELECTRIC MANUFACTURING CO., No. 513 Elm street, are bringing out a new ceiling block, the main features of which are the ease and convenience with which it can be attached to the ceiling, and with which the fuse wires can be renewed. It is made of extra quality porcelain in two parts, which lock together by a simple device which at the same time completes the connections between the lamp flexibles and the mains, and also tightens the terminal connections of the fuse wires.

THE WESTERN ELECTRICAL SUPPLY CO., 310 North Third street, who went into business only a year ago, report a very successful run during the year. They are special agents for the Western states for Grimshaw wires, the demand for which is steadily increasing. Mr. T. J. Wilson is president and manager and Mr. P. H. Reichardt, vice-president.

NEW ENGLAND TRADE NOTES.

THE HOLYOKE MACHINE COMPANY, of Worcester, Mass., are doing a large business in fitting up electric light and power stations with shafting and pulleys, and have deservedly earned a reputation for first-class work. Amongst their most recent sales are the following: The Toledo Consolidated Street Railway Company, Toledo, O.; David Robinson & Sons, Toledo, O.; Memphis Electric Light and Power Company, Memphis, Tenn. They have also just completed the installment of the shafting and pulleys for the Quincy Street Railway Company, Quincy, Mass.

A. W. WHITCOMB, of Worcester, is enjoying a run at present on his automatic dynamos and motors of from 10 to 150 lights and from ¾ to 20 h. p. Mr. Whitcomb has exceptionally good facilities for turning out first-class work, and that his goods are meeting with general approval is amply vouched for by the number of excellent testimonials which he has recently received.

THE SCHUYLER ELECTRIC COMPANY, of Middleton, Conn., have nearly completed a large addition to their factory, comprising a new brick building 206 feet long by 60 feet wide by 3 stories high. The Schuyler Company are extremely busy at present with dynamos and motors, and are also doing a large amount of work in switches and other electrical apparatus.

THE MATHER ELECTRIC COMPANY, Manchester, Conn., are busy preparing an entirely new line of motors, the smaller sizes to be two pole, and the larger sizes of the four pole type. They will be totally unlike the old Mather pattern, and will run at a much slower speed. The first of these motors will be ready in about a month. The Mather Company are also manufacturing a very complete line of measuring instruments, which are attracting attention for their accurate properties and extra good finish.

THE UNION ELECTRIC MANUFACTURING COMPANY, of Bridgeport, Conn., has been organized under the laws of the State of Connecticut, with a capital of $50,000, in 2,000 shares of $25 each. The following five well-known gentlemen have each taken 400 shares: F. A. Gilbert, Boston; James English, New Haven; John C. English, New Haven; Horace T. Clark, Bridgeport, and John M. Orford, Bridgeport. The object of the company is to buy or sell electric machinery, appliances and supplies for electric light, heat, and power, and the factory and offices will be located in Bridgeport. Messrs. J. C. English, Clark and Orford have sold their stock in the Bryant Electric Company, of Bridgeport, and Mr. W. C. Bryant, of the same company, has bought it. The prospects of the new company are very bright, and with such a combination of men so favorably known among the electrical fraternity the success of the company is assured.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of January 17, 1891, from New York, Boston and Washington; Pittsburgh, January 16.

VOL. XI. JANUARY 28, 1891. No. 143.

THE INVENTORS OF THE ELECTRIC MOTOR.—IV

WITH SPECIAL REFERENCE TO THE WORK OF THOMAS DAVENPORT.

BY

Franklin Leonard Pope

EARLY in the spring of 1838, Davenport discovered the principle of the core moving within the magnetic field of a solenoid, which afterwards came to be well known by the name of the "axial magnet." Entertaining the conviction that in this principle lay the germ of an important improvement in electro-magnetic engines, due to the possibility of greatly increasing the effective length of the stroke, he at once prepared and filed in the Patent Office at Washington, a caveat describing his discovery, and giving an outline of the manner in which he proposed to apply it for the movement of machinery. Although this discovery was no doubt original with Davenport, the phenomenon had been observed by Peter Barlow as early as 1822.[1] So far as record evidence goes, however, the caveat of Davenport is believed to be the earliest proposition to apply this principle in any manner for industrial purposes.

As this caveat has never been published, a copy of it is given below, procured by permission of the heirs of the inventor, from the secret archives of the Patent Office at Washington.

The Caveat of THOMAS DAVENPORT, of the City of New York.

The said Thomas Davenport, having invented a new machine of which a description is hereinafter contained, and desiring further time to mature the same, files this his caveat in the patent office of the United States, and prays protection of his right till he shall have matured the same.

The design, purpose, and distinguishing characteristics of his invention are as follows:

Said machine is designed to create or supply a power for any purpose to which animal, mechanical or other physical power can be, or is, applied to move bodies and machinery of every description. It is composed of an instrument denominated in science a helix, which is formed by winding insulated wire proper for the purpose around a hollow cylinder or other shaped tube of thin metal or other suitable substance incapable of being magnetized, in the usual manner and proper quantity in making helices. Galvanism being passed through such wire in proper quantity the helix is complete. The helix should be so formed that the internal hollow will be smooth, firm and uniform throughout, so as to permit a long, straight and uniformly thick piece or bolt of iron of the same shape and nearly exactly filling said hollow cylinder or tube to pass and repass longitudinally through it with as little friction or obstruction as possible. The end of a bolt or piece of iron fitting said tube or hollow cylinder, as before described, is then inserted a short distance into said hollow cylinder or tube, and the helix being galvanized the bolt will be drawn forcibly entirely into said tube and a motion be thus created. It is this machine, composed of the helix and bolt of iron (neither of which do I claim separately), thus producing motion, which I claim as my invention. I have so far improved it as to produce a reciprocating motion by which a crank may be turned in the following manner: I take two of the above machines, and the helices being placed perpendicular, I attach the two bolts at each extremity of a balance or walking beam. I then alternately galvanize each helix, and while one is galvanized, I take off or suspend the galvanism from the other. The consequence is, that the helix which is galvanized draws down its own bolt, and the other, not being galvanized, allows its bolt to ascend. As soon as the latter bolt has nearly reached the top of its helix I remove the galvanism from the former helix and galvanize the latter. The bolt of this is then drawn down and the other bolt ascends, and so on alternately. Intermediate the centre of the balance or walking beam and one of its extremities, at a suitable distance between, is attached a rod which descends to a crank, and as the balance beam moves up and down the crank is turned and turns a wheel band or other instrument to communicate power or produce motion. I put a balance wheel on the axis of the crank, and the axis of the crank forms a convenient means of letting on and suspending the galvanism as before described. In order to do this, separate pieces of silver, copper and other suitable metal are fastened to the axis so as to go about half way around it, forming a semi-circle flat and smooth. The conductors from the battery and the conductors to the helices are placed in contact with those pieces of metal but so as not to communicate galvanism to each other, unless through the medium of those pieces of metal. Then as the axis revolves when the revolution brings the conductors both in contact with their pieces of metal their helix is galvanized, and when, by such revolution the contact ceases, the galvanism of the same helix is suspended, and so of the other helix.

Dated New York, May 5th, 1838.

Attest:

E. PAINE. THOMAS DAVENPORT.

Respecting the work which was carried on during the year 1838, I have been able to obtain but little information. There are indications that matters in New York were practically at a standstill. It was a period of extreme financial depression, in which even well established interests experienced no little difficulty in meeting their liabilities and carrying on their business. In February, 1839, Davenport received a letter from John H. Smith, of Glasgow, a nephew of Junius Smith, who organized the corporation which built the celebrated steamship the *British Queen*. It appears that Smith, who had visited America in the preceding summer, had seen a model of Davenport's apparatus in operation at the Mechanics' Fair in Castle Garden, and in his letter he intimated his desire to undertake the introduction of the invention in Great Britain, on Davenport's behalf. Writing from Brandon, in reply to this and other letters from Smith, on August 15, 1839, Davenport says:

---

[1] This effect was noticed by Barlow in the course of an experiment in magnetizing a steel needle which was placed within a helix wound upon a glass tube. His own account of it is as follows:

"In performing this experiment, I employed a glass tube about 5 inches in length and ¼ inch in diameter; and it was observed, when the needle was placed in it, so that one-half of it projected beyond the end, that the moment the plates reached the acid, the needle was drawn instantly to the middle of the tube, and while the contact was continued it was held suspended in the centre of the tube when the latter was held vertically; the suspending power of the spiral exceeding the power of gravity. (The connection of the spiral with the conducting wires is here supposed to be made before the plates are immersed in the acid.)

"This effect is very curious, because the needle here remains suspended in the open space, directly in the axis of the tube, and not attached to either side as in the usual cases of suspension by attraction." BARLOW: *Essay on Magnetic Attractions*, etc. [2d edition, 1823.] p. 262.

The writer is indebted to Charles L. Clarke for the loan of the exceedingly rare work from which the above extract was taken.

The following editoral note referring to the same phonomenon appears in Sturgeon's *Annals*, vol. ii., p. 80 (Jan. 1838): "In answer to our correspondent, who wants to know if it be possible to suspend a needle in the air by transmitting an electric current through a helix in which the needle or bar is lying, we must say, yes. The fact was first shown at the London Institution, Moorfields. The battery employed was contrived by Mr. Pepys, and consisted of a single pair of plates of copper and zinc, each about 50 feet long and 2 feet broad, formed into a spiral on a cylindrical nucleus of wood, and placed in a barrel or circular wooden trough which held about 50 gallons of acid solution. The experiment may be made, however, with a battery of one square foot of each metal, immersed in a strong solution of nitrous acid. The helix must be of narrow bore, of 6 or 8 layers of spirals, and held vertically. The gravitating propensity of the needle may be much reduced by holding a bar magnet at a small distance above the helix."

In Alfred Vail's *American Electro-Magnetic Telegraph*, p. 59, is an account of "An Interesting Experiment of Supporting a Large Bar of Iron within the Helix. Discovered by Mr. Vail, Jan. 1844," which, so far as the writer is aware, is the earliest *published* account of the suspension of a soft iron bar of any considerable weight. The account is in the following words:—"It has been shown many years since that a magnetic needle would be drawn into and suspended within a helix conveying a galvanic current, and that in the case of using large bar magnets, the coils of helices might be made to move over them as in De la Rive's rings; but in no instance I believe has it been recorded or observed, that a bar of iron weighing a pound or more could be drawn up into the helix and there sustained in the air, as it were, without support. If the helix be connected with from 6 to 12 pairs of Grove's battery, the bar may be drawn up into its centre and there sustained in a vertical position by the action of the helix, forming an exceedingly interesting and paradoxical experiment."

> I have experimented these 18 months past with my own limited means, having constructed machines on more than 30 entirely different plans; making great improvements in the power in proportion to the weight, &c. . . . . . I have no doubt but that the power is unlimited, which can and ultimately *will be* successfully applied to all purposes for which steam-power is now used. . . . . . . An attempt is making in New York by some individuals who have a machine now exhibiting in Gold street, to *monopolize*, as they say, the business of Electro-magnetic speculation. They have obtained a charter, and are offering for sale shares of stock; but their machine, although inferior in principle of application to any ever before exhibited to the public, is precisely on the plan of one constructed by myself in the winter of 1835, a part of which is now at this place [Brandon].

In a subsequent letter to Smith, dated in New York, December 13, 1839, Davenport mentioned that he was driving a rotary printing press with a machine weighing less than 100 pounds.

In January, 1840, Davenport commenced the publication of a journal entitled *The Electro-Magnet and Mechanics' Intelligencer*. This was a small folio sheet 12 by 16 inches, and as its title-page announces, was printed on a press propelled by electro-magnetism. As a matter of curiosity we give a fac-simile of the head of this somewhat unique and not particularly well-printed publication. Copies of the two first numbers issued have been preserved. It is not known how many, if any, subsequent numbers were issued. Among the editorial remarks in the second number I find the following, which are quoted as explanatory of the plan and scope of the undertaking:

> The first number of the *Electro-Magnet* was issued on Saturday, January 18, 1840, which was the first paper ever printed by the power of Electro-Magnetism or Galvanism. The project was proposed and set on foot for the express purpose of bringing before the public some tangible illustration whereby the power might be brought forward upon as cheap and prudent scale as possible. How far we have succeeded, time must show. . . . . . As the second number of our publication is before the public, we would respectfully call the attention of those who wish to advance the cause of philanthropy to come forward and assist us in our experiment. That we may be considered chimerical by many we doubt not; but when all things are fully proved we shall hope for a better fate than many of our predecessors.

On January 28, 1840, only three days later, in a letter to his brother, in Brandon, he feelingly portrays some of the miseries which beset the path of this, the pioneer effort in electrical journalism:

> I have been obliged to bear the whole load in starting the paper and have no writer to aid me yet. I have talked with some, and find that it will cost $10 per week for editorial articles (which accounts for no more original matter), yet I intend to have friends enough soon that will help without expense to me. . . . . The truth is, I am now in the worst pinch in regard to means for supporting my family that I ever have been, yet my prospects are the most flattering, and I think the most sure to net me something handsome as early as spring. You see I have no way to get a few dollars in a place, except by the prospect of getting subscribers, which I have not yet tried to do. I have only to take time and make my trade in a lump.

A few months later Davenport appears to have made a second essay in the way of a journalistic enterprise, of which, so far as is known, only a single number was issued. The new undertaking was somewhat more ambitious in character, being printed in quarto form upon a sheet 16 by 22 inches. This journal was entitled *The Magnet; Devoted to Arts, Science and Mechanism*, and was "edited by S. J. Burr, secretary, U. S. Society of Science and Mechanism," presumably at the munificent salary of $10 per week, which in fairness it must be stated, was every cent that the work was worth. As a matter of interest, we copy the advertisement which appeared at the top of the first column, together with the prospectus:

> *The Greatest Discovery of the Age.*
>
> The attention of the scientific, mechanical, and curious is respectfully invited to the exhibition of LIGHTNING IN HARNESS, which is this day opened at No. 4 Little Green street. (Little Green street is between Broadway and Nassau street, and runs from Maiden Lane to Liberty street.)
>
> The exhibition of Davenport's electro-magnetic engine will continue open this day, from 9 A. M. to 10 P. M.
>
> The engine is of sufficient power to drive a printing press, and those who witness the exhibition will find it printing the DECLARATION OF INDEPENDENCE.
>
> The proprietor has been induced to exhibit his electro-magnetic engines especially upon this day, for what can be more appropriate than, upon the anniversary of our nation's birth, to print the Declaration of Independence and send it by lightning throughout the whole world.
>
> Admittance free.
>
> July 4, 1840.

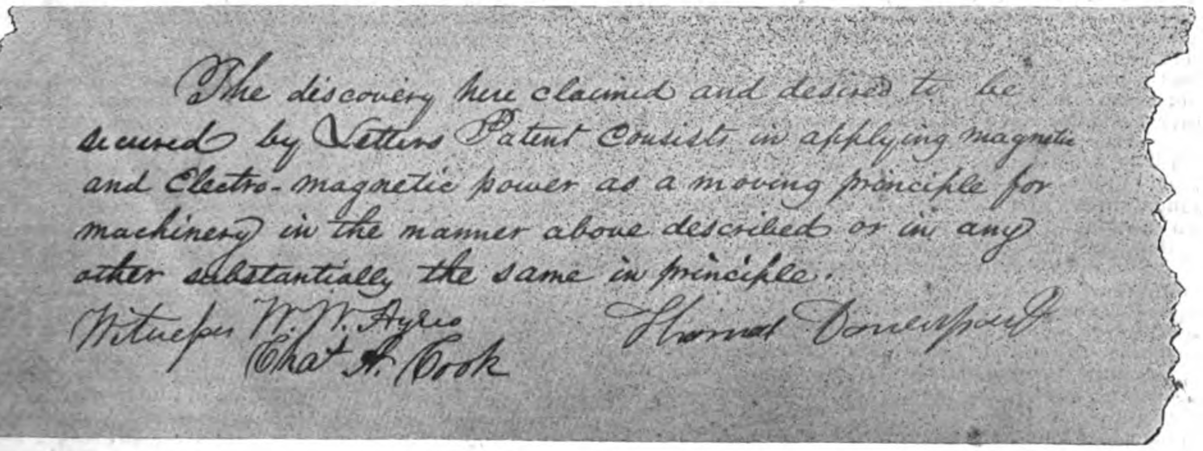
> PROSPECTUS OF THE MAGNET.
>
> We present our little work to the public with great confidence and for several excellent reasons: First. It is printed upon a new and improved conical rotary press. Secondly. This press is worked by our electro-magnetic engine. Thirdly. Both are wholly American. The first number of the paper is published on the anniversary of our national independence, and offered at a cheap rate to the patronage of the lovers of truth, and those who devote time and labor to mechanical and scientific pursuits.
>
> Though the investigation of electro-magnetism will form the principal feature of our journal, it is not intended to confine its columns to that interesting science; we shall fill our pages with such authentic matter as may come within our reach upon all scientific and mechanical subjects.
>
> With respect to electro-magnetism, it is the intention of the publisher to advance tangible proofs that this power has already triumphed in moving machinery. It is also his design to make known all the experiments made by him since December, 1833, which go to corroborate his views on this subject, with wood cuts, illustrating various models and machines, together with the laws of electro-magnetism, and the great advantage this wonderful power has over steam, in regard to safety, cheapness, and convenience. In the mean time, the experiments of others, more experienced in the science of electricity, galvanism, magnetism and electro-magnetism, will be noticed in order that the reader may get a general idea of the science, and the laws by which they are governed, and by which we are guided in controlling and working the powerful and mysterious agent. It is not our intention to make the subjects tedious, nor the articles too laborious for the ideas of readers in general.
>
> We shall treat upon the different branches of science, and the various inventions and improvements that shall be made known, as also those at present in operation, together with such miscellaneous and interesting matter as shall appear from time to time.
>
> Any objections or difficulties that may be advanced by different individuals, in regard to the application of electro-magnetism as a motive power, we shall be pleased to receive, and shall consider it a favor to communicate with them through the columns of the Magnet.
>
> Several scientific gentlemen of our city, Boston, and Philadelphia, have already engaged to become contributors to make our paper interesting and useful to all classes.
>
> THOMAS DAVENPORT.
>
> NEW YORK, July 4, 1840.

Two or three machines of different design were employed at different times, in driving the printing press. One of them was a helix machine, constructed upon the general plan proposed in the caveat of 1838 which has been given above.

The experiments of Davenport during the season had been so numerous and so costly that he again found himself at the end of his resources, and was reluctantly compelled to suspend operations. Receiving encouraging letters from Great Britain, he finally made arrangements to proceed to that country in order to personally negotiate the sale of his foreign patents, and it was only the lack of promised pecuniary assistance which failed to reach him on the very morning of his intended departure, that prevented him from being one of the unfortunate passengers of the ill-fated steamer President, which foundered at sea, carrying with her every soul on board.

Very little record remains of the labors of Davenport for some time after the occurrences which have just been narrated. It was, however, at some time during this period, that he experienced one of those cruel disappointments by which fortune sometimes seems to delight in making a foot-ball of the struggling inventor. The story of this misfortune is best given in Davenport's own words:

> A gentleman residing in Ohio, finally proposed to assist me to an amount which I considered would enable me to put the electric-motor power on such a footing that it should no longer prove problematical whether electro-magnetism could be used instead of steam. As I had for a long time been completely destitute of means for carrying on my business, and even for comfortably supporting myself and family, I now felt not only relieved as regarded my daily subsistence, but I was much elated at the idea of having sufficient funds to build a proper Electro-magnetic engine.
>
> This gentleman funished me with $8,000 in Ohio bank notes. Of these notes I had used only $10 when I was informed that the bank that had issued the notes had broken, and that my money was good for nothing. This proved to be the fact, I never received $10 in cash for the remaining $2,990. After struggling along for nine months more in trying to convince my friends that the object of which I had so long been in pursuit was still worthy of their attention, I reluctantly gave up all hope of further assistance, and in the fall of 1842 moved my family to Brandon, Vt., where I resumed work at my trade as a blacksmith, which was then my only resource to gain a livelihood.



The discovery here claimed and desired to be
secured by Letters Patent Consists in applying magnetic
and Electro-magnetic power as a moving principle for
machinery in the manner above described or in any
other substantially the same in principle.

Chas A. Cook

CLAIM OF DAVENPORT'S PATENT. NO. 132 OF FEBRUARY 25, 1837.
[*Fac-Simile from Original Specification in Archives of Patent Office.*]

Early in 1843, the inventor's nervous system, enfeebled by so many years of incessant toil and anxiety, gave way under the strain, and a protracted and dangerous illness ensued, which left him with a constitution permanently impaired. After residing two or three years in Brandon, he retired to a small farm in Salisbury, Vermont, where he passed the few remaining years of his life. He could not, however, wholly withdraw his mind from the fascinating science which had for so many years been a part of his very life, and in the retirement of his quiet home, he continued his studies and experiments in electro-magnetism.

In February, 1849, a memorial of Dr. Charles G. Page was presented in the United States Senate by Senator Benton, asking for the appointment of a committee to examine the merits of an invention for applying electro-magnetism to the purposes of navigation and locomotion, and a committee of seven was appointed for that purpose. In March an appropriation was granted, in pursuance of the recommendation of this committee:

> For testing the capacity and usefulness of the electro-magnetic power, as a mechanical agent for the purposes of navigation and locomotion, and the probable cost of using the same according to the invention of Professor Page, the sum of *twenty-thousand dollars*, to be expended under the direction of the Secretary of the Navy in making a practicable experiment of said invention according to the plans to be proposed and conducted by Professor Page.

From time to time accounts of the experiments of Dr. Page found their way into the journals of the day, and one of these notices, coming into the hands of Davenport, led him to send a communication to a local newspaper, which is not only valuable in itself, as a concise review of the author's own work, but because it was the occasion that led to an interesting correspondence between Davenport and Page, the essential parts of which are printed herewith, and which form a contribution of no inconsiderable importance to the history of the development of electro-magnetism as a motive power:

> [*From the Brandon Post, Sept. 26, 1850.*]
>
> ELECTRO-MAGNETISM TRIUMPHANT OVER STEAM.
>
> Mr. Welch:—Will you allow me a small space in the *Post* for the purpose of making a few remarks respecting Professor Page's successful experiment in applying Electro-Magnetism to propelling machinery, as described in the following article which recently appeared in the *National Intelligencer:*
>
> > **Electro-Magnetism as a Motive Power.**
> >
> > Professor Page, in the Lectures which he is now delivering before the Smithsonian Institution, states that there is no longer any doubt of the application of this power as a substitute for steam. He exhibited the most imposing experiments ever witnessed in this branch of the science. An immense bar of iron, weighing 160 pounds, was made to spring up by magnetic action, and to move rapidly up and down, dancing like a feather in the air, without any visible support. The force operating upon this he stated to average *three hundred pounds* through ten inches of its motion. He said he could raise this one hundred feet as readily as through ten inches, and he expected no difficulty in doing the same with a bar weighing one ton or one hundred tons. He could make a pile driver or a forge hammer, with great simplicity, and could make an engine with a stroke of six, twelve, twenty, or any number of feet.
> >
> > It looked very unlike a magnetic machine. It was a reciprocating engine of two feet stroke, and the whole engine and battery weighed about one ton. When the power was thrown on by a motion of a lever, the engine started off magnificently, making one hundred and fourteen strokes per minute; though when it drove a circular saw ten inches in diamater, sawing up boards an inch and a quarter thick into laths, the engine made but eighty strokes per minute. There was a great anxiety to obtain specimens of the laths sawed in this way to preserve as trophies of this great mechanical triumph. The force operating upon the magnetic cylinder throughout the whole motion of two feet, was stated to be 600 pounds when the engine was moving very slowly, but he had not been able to ascertain what the force was when the engine was running at a working speed, though it was considerably less. The most important and interesting point, however, is the expense of the power. Prof. Page stated that he had reduced the cost so far that it was less than steam under many and most conditions, though not so low as the cheapest steam engines. With all the imperfections of the engine, the consumption of three pounds of zinc per day would produce one horse power. The larger his engines (contrary to what has been known before) the greater the economy. Prof. Page was himself surprised at the result. There were yet practical difficulties to overcome; the battery had yet to be improved; and it remained yet to try the experiment on a grander scale, to make a power of *one hundred horse* or more.
>
> As I am confident that the results of the experiments of this enterprising and scientific gentleman will open the eyes of the people and the purses of capitalists, sufficiently to soon place on our lakes, rivers and railroads, a safer and more convenient power than steam, I hope I may not regret so much in future as I have for ten years past, that the paralyzing hand of *poverty* has for-

bidden any attempt on the part of myself to prove to the world, what as early as 1833, I believed could be done within the space of five years. At that time galvanism appeared to me to have the same relation to the power of an electro-magnet that water does to the power of a steam engine, and I had no doubt but that I could convince the whole sensible world of the fact, by applying the power of a small electro-magnet to moving the lightest machinery. But in this I was disappointed. I found the power more controllable than the minds of men, and compliments more plenty than money.

Having devoted the most part of seventeen years of my life in laboring to apply electro-magnetism to useful purposes (and without receiving any remuneration), it may not be improper for me to state to the public the power and size of some of the electro-magnetic engines which I have invented and applied to the moving of machinery, that they may be compared with the engine lately constructed by Prof. Page. Early in 1838 I ascertained that a bolt of iron could be drawn with great force into a helix whenever the battery current was suffered to pass through the coil. I immediately constructed a small engine on this principle, which, when in motion, very much resembled a little steam engine with two perpendicular cylinders. During the same season I filed a caveat for this improvement in the United States Patent Office, and sent several models to Europe. A patent for this invention was obtained in England and the Provinces, and money paid into several other European Patent Offices where no letters patent have ever been obtained.

In 1839 I experimented on a much larger scale with the magnetic cylinder or helix, and constructed a helix two feet in length with an aperture through the centre two inches in diameter. A bolt of iron 2 feet long and 2¼ inches in diameter, weighing about 28 pounds, was forced into the helix when the current of galvanism passed through the wire, with a power equal to 6 pounds to the square inch of its diameter. This test was made with the helix and bolt placed in horizontal position, so that the weight of the iron should not be reckoned.

When the helix was in a perpendicular position and raised one foot from a platform, with the lower end of the bolt resting upon the platform, and the upper end entering one foot into the helix, the battery current would raise this bar of iron with such force that it would often pass entirely through the coil, 2 feet in length, and fall upon the platform.

In January, 1840, I had completed an engine with two magnetic cylinders weighing 50 pounds each. The engine made a 12-inch stroke and weighed about 200 pounds. The battery was made of lead and zinc plates 2 feet long and 5 inches wide, weighing in its most improved state 100 pounds. In the same month I commenced publishing a newspaper, which was printed on a press propelled by this engine. When the press worked off but 10 papers per minute, the engine made 120 strokes in the same time. Many who witnessed the working of this machine, estimated it to be a two horse power, but from my own tests, I could not make it exceed the power of one horse. The cost of zinc and acid in working did not exceed 25 cents per day. In the course of my experiments, up to the time of printing by this power, I had constructed in all more than 100 engines of various dimensions, and all different in point of construction, for the purpose of ascertaining the best proportions and mechanical arrangements for the increase of power. My experiments with helices, using long and short, large and small, hollow and solid bars of iron, were very numerous. My press was first moved by a horizontal helix engine, next by a rotary, and lastly by a perpendicular double helix engine. Now, as Prof. Page's experiment with 160 pounds of iron "dancing like a feather in the air" seems to me to be precisely like the experiment I made in 1839, when the 28 pounds of iron jumped through a helix two feet in length, by magnetic action, and as the Professor's engine is constructed on the same plan and principle as my own above described, I presume the scientific gentleman lays no claim to having presented any *new route* in his application of the power, or to have made any important improvement whatever in my invention. If Prof. Page, by the completion of his engine, has finally come to the point at which I arrived ten years ago in testing electro-magnetism as a prime-mover in the arts, and has expended as much money in the series of experiments which he of course would be obliged to make, I think I could have saved him the needless expenditure of several thousand dollars, by giving him the results of some of my experiments in 1838-9-40, which I should have been happy to do, if I had been consulted in due time.

THOMAS DAVENPORT.

SALISBURY, VT., Sept. 12, 1850.

The publication of this communication drew forth the following letter from Professor Page:

[*Letter of Charles G. Page to Thomas Davenport.*]

WASHINGTON, D. C., Oct. 2, 1850.

Dear Sir:—I have received this day your communication in the *Brandon Post*. I have been aware from the beginning of your experiments with the helix, and although we were operating entirely independent of each other, it will no doubt be gratifying to you to know of a promise of success in the common cause. I believe there is nothing in my improvements that conflict in any way with your inventions, but should it ever prove to be the case, I think we could make an amicable arrangement. I commenced my experiments on the helix primarily in 1830, and made several miniature models, and published accounts of several of them in the early part of 1837. In 1838, in the winter, I think, while I was in Davis' shop in Boston, a gentleman from New York called and said that you thought you could get power in that way, but that you had not yet arranged any machine. My experiments and little models had been successfully tried long before that, and I have always believed and am satisfied that I was the first that ever attempted to get power in that way.

In 1843 I made a great improvement on this principle, and many more since, without which I am satisfied nothing could be done to render the power available.

I have always looked with pleasure upon your zeal and ingenuity in this matter and when speaking in public have always alluded to you in terms of commendation, and although your article was no doubt written with feeling, yet I hope you will not repeat it until we can fully understand each other.

Respectfully, your obedient Servant,

CHA'S. G. PAGE.

THO'S. DAVENPORT, Esq.

[*From the Brandon Post, October* 31, 1850.]

WASHINGTON, D. C., Oct. 24, 1850.

Mr. Editor:—I notice in your paper a communication from Mr. Davenport, in which he gives an interesting historical account of his experiments in electro-magnetism, and concludes that he was in advance of myself in respect to the peculiar plan of operation which he describes. According to his own statements he *was* in advance of me in respect to the scale of magnitude of his experiments, and from the size of battery which he employed that would have necessarily followed. But the attempt to apply this peculiar principle of action to an engine for mechanical purposes was made and published, so far as I can learn, first by myself, and long before Mr. Davenport states that he was first aware of the fact that a bar of iron would be drawn into a helix. This fact has been long known to the world, having been first published by Mr. Barlow in 1823, and I apprehend that the reason why it has been so little thought of as a source of mechanical action, is that the force thus exerted was so very feeble compared with the attraction of the electro-magnet. As to raising a bar, I can of course claim no originality, and the raising of a bar of 600 pounds, which I now do readily, presents a difference only in degree from the experiment of Mr. Barlow in 1823 in raising a small bar, perhaps of only one ounce. But the peculiar improvements by which I raise so great a weight with so *small an expenditure* of galvanic power are novel and original with myself. Mr. Davenport is entitled to great credit for his ingenuity and zeal in the pursuit of electro-magnetism, and I have always viewed with much interest his early perseverance in this matter. But it is due to himself, the community and myself, that I should make this statement, and to add that I do not feel indebted to any one for the peculiar views which I have long entertained in regard to the plan of operation based upon the known fact above mentioned.

CHAS. G. PAGE.

In view of the historical interest attaching to the inquiry, the author has made every effort to verify the statement made by Professor Page in the two preceding letters in respect to his publication in 1837, of accounts of experiments with the helix and core, but without success. From other publications made by Professor Page, it seems impossible to avoid the conclusion that the dates given by him must have been the result of some misapprehension. In an article published in *American Journal of Science* in 1845, vol. xlix, p. 131, he says:

> This new species of electro-motion, which by way of distinction I denominate the axial reciprocating engine, was *unsuccessfully attempted in the year* 1838, and notice made of it *in this* journal (vol. xxxv for 1839, pp. 261 and 262) together with *some other experiments upon the interior of helices.* My failure at that time was for want of suitable batteries, etc. . . . . . .
> To sustain a small needle within the helix is a trite experiment, but by the arrangements which I have adopted, a bar of iron or steel (which becomes instantly and powerfully magnetized) is

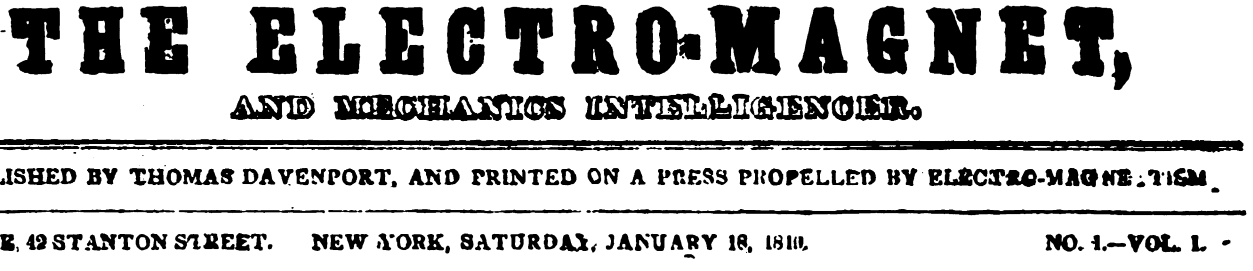
---

[2] The improvement here referred to by Professor Page, is probably that embodied in the engine which he exhibited in New York in the fall of 1851, and which is described with illustrations in the *Scientific American* of November 15, of that year (vol. vii., pp. 65, 67). This machine was fitted with a range of hollow helices formed of square wire. A sliding commutator was so arranged as to pass the current through three successive coils of the series at the same time, current being cut off from each rear coil in succession, and thrown on the coil in front of the core in the direction in which the latter is moving. Thus a stroke of any length in either direction could be given to the moving core. The battery used is stated to have been 40 pairs of 10 inch Grove's. This form of motor had been used in Professor Page's well-known experiment in propelling an electro-magnetic locomotive on the Baltimore & Ohio Railroad in April of the same year.

sustained entirely free from any visible support, and this too by the action of only six small Grove's batteries. This is almost a realization of the fable of Mahomet's coffin, or the statue of Theamicles. When the helix is connected with six pairs Grove's in good order, it will draw up within its centre a bar of iron or steel weighing two or three pounds and sustain it with its upper end projected above the helix

He then goes on to give a description of his well known axial reciprocating engine, for which he took a patent January 31, 1854, and which is described in many works on electricity and magnetism.[3]

Referring to the notice in vol. xxxv of *American Journal of Science* of which Page speaks in the above extract, I find that it describes an apparatus consisting of a pair of helices, with U-shaped cores thrust into them at each end, so that the four poles will meet in the centre of the helix. It is distinctly stated that this apparatus was contrived Jan. 11, 1838, but it is not properly an axial magnet, nor is any mode of application to the moving of machinery described. The inference seems unavoidable that Professor Page must have been in error as to his dates, and that Thomas Davenport is really entitled to priority in the application of axial magnetism to the movement of machinery, as set forth in his caveat of May 5, 1838, and as reduced to practice by him in 1838-39-40.



THE ELECTRO-MAGNET,

AND MECHANICS INTELLIGENCER.

PUBLISHED BY THOMAS DAVENPORT, AND PRINTED ON A PRESS PROPELLED BY ELECTRO-MAGNETISM

OFFICE, 42 STANTON STREET. NEW YORK, SATURDAY, JANUARY 18, 1840. NO. 1.—VOL. I.

FAC-SIMILE, FULL SIZE, OF THE HEADING OF DAVENPORT'S ELECTRICAL JOURNAL, ISSUED IN 1840.

[*Letter of Thomas Davenport to Charles G. Page.*]

SALISBURY, Oct.——, 1850.

Dear Sir:—Yours of the 2d inst. was duly rec'd. When I wrote the article which you noticed in the *Brandon Post*, I had no knowledge of the fact that Congress had appropriated any moneys for testing the availibility of electro-magnetic power. Since then, have received your report to the Secretary of the Navy on the subject of electro-magnetism as a moving power. I am truly gratified to learn that your experiments have resulted so favorably. I believe, however, that if I could have had in 1840, one half the amount of money that you have expended, I should have produced more power and fully as economically. I question whether, in proportion to weight, your machine actually exceeds in power the helix machine with which I printed a newspaper in 1840. But, the improved state of the galvanic apparatus would probably render your power a cheaper one. I perceive that you have made a great many experiments which were precisely like those I had tried, excepting that yours were on a larger scale. The impossibility of my obtaining funds to build larger caused me much regret. In completing my engine for printing, I had used up all the means I possessed, and all that I could get, for I had tired my friends with my solicitations for funds. After trying more than a year without success, I gave up all hopes of enlisting individuals any farther in the enterprise, and I then thought of applying to Congress for an appropriation for the purpose of testing the power on a larger scale. I asked the opinion of many intelligent and influential individuals in regard to my plans, but they invariably gave me unfavorable answers. In 1845-6 I wrote to some gentlemen and members of Congress on the probability of my getting an appropriation from the Government, but their answers were generally discouraging. But I will not tire you at this time with an enumeration of my misfortunes, for it pains me much to call to memory the many distressing circumstances in which I have been placed in consequence of my zeal in the cause. You mention that you believe that you are the first that ever attempted to get power with the helix, and that you had successfully tried a model previous to 1838; also that some of your experiments in the helix were published prior to that date. I find in Davis's "Descriptive Catalogue of Apparatus and Experiments," published in Boston in 1838, the following apparatus described: "Page's revolving helix," "Page's revolving helical ring." These experiments seem to be on the same principle as the "floating helix" and "De la Rive's ring."[4] In your improvements in the "floating helix," it appears that you had no idea of accumulating *power* in that way, for in your letter to me dated Boston, April 28th, 1838,[5] you have said nothing about any experiments with the helix, although you mention a variety of other experiments which you have made in producing rotary motions, without changing poles, and which you considered was an improvement on my system of changing the polarity of the magnet. You also stated in the same sheet, that you could show good reasons why the power would not admit of "indefinite increase," but must be confined to the power of that of one or two men. *Since I first saw the power of an electro-magnet exhibited, any idea that the power could not be indefinitely increased, seemed to affect me with a peculiar disagreeableness.* I write you thus plain, because I have had strong feelings on the subject, and retain them yet. I believe that my zeal and attachment to, and inventions in, electro-magnetism have been of great value to science and the arts, to government and to the whole world, and this I shall endeavor to show in a publication which I hope to have prepared in a few weeks, in which I intend to fully show my position in the matter.

You mention in your letter of the 2nd inst. that if your improvements in any way conflict with my inventions, there could no doubt be an amicable arrangement made between us. It strikes me that if Government has taken the business in hand to perfect the application of this power to moving machinery, that Congress would be the proper body for me to look to for compensation for what I have done in the premises. I should be happy, however, to receive suggestions from you with regard to the best course for me to pursue. In the meantime, I hope that Congress will make still further appropriations, that you may continue on in the noble cause.

For the last four years I have been experimenting in electro-magnetism on a plan for applying the power to new purposes; and have succeeded to my full satisfaction. This invention I consider of very great importance to the public, and I hope to be able in a few months to present you with a model for examination.

Respectfully your friend and fellow-laborer,
THOMAS DAVENPORT.

[*Charles G. Page to Thomas Davenport.*]

WASHINGTON, D. C., October 22, 1850.

Dear Sir: I have this day received your kind letter and although I differ with you in opinion on its most important points, still I believe you to be as sincere as you are zealous. I do not remember the letter of 1838 you refer to, but it has generally been my practice in writing to others upon the subject, to withhold such information as would give them an advantage over myself by giving them the benefit of my own inventions. However in 1838 and after, and in 1836-7, I was fully of the belief that an economical power could not be obtained, unless the difficulties of the time required to charge and discharge magnets and the influence of secondary currents could be overcome. These difficulties always increase with any increase in the size of the engines. I threw out all these objections in *Silliman's Journal* at that time, but I hoped and believed there would be a remedy; I was constantly searching after it, and at last I found it. It was only when I found it, that I thought the way was clear. You must estimate the power of your engine much too high. Your printing press was a very small one, and it would not have required, I think, $\frac{1}{10}$ horse-power to drive it at the rate you mention. I send you a pamphlet containing an account of the performance of my engine which was made about five years since, and which after I got it into the best working order I showed to Congress, working a planing machine (small one) and afterwards carried to Tower's printing office to test it. This engine had by accurate measurement, ¼ of a horse-power and yet you see how large a press it worked at the rate of twelve hundred impressions per hour. There are some other points in your published article which do not seem to me to be correct, as to estimates, etc. But there is no reason why I should raise a discussion now about them. You will notice in the pamphlet that I had given you credit for your labors (see page 6). There seems to be no hope from Congress now. They have taken the ground that it is a matter of individual enterprise, and on that ground they refuse to appropriate further for my experiments. I applied for forty thousand dollars to build a large ship with an engine of one-hundred horse-power, which they refused without a count.

---

[3] See Davis's *Manual of Magnetism* [12th edition] p. 182; U. S. Letters Patent, No. 10,480; Martin and Wetzler, *The Electric Motor*, etc., p. 79.

[4] De la Rive's ring is a small helix of thin wire in the form of a vertical annulus which is mounted on a float, having a small plate of copper attached to one end and a corresponding plate of zinc to the other end, which hang below the float. The whole arrangement is then placed upon the surface of a vessel of acidulated water, which causes a current to pass through the ring. If the pole of a bar magnet is presented to the ring, the latter will move towards the centre of the magnet, passing over the bar. It is in fact an inversion of the solenoid and core, and involves precisely the same principle. (See *Davis' Manual of Magnetism* [12 Ed.], p. 115.)

[5] See *ante*, p. 71.

The great feature of my engine is the manner in which I overcome the difficulties I spoke of, and you will I am sure be gratified when you come to know the plan. It has never been made known in public yet, but by next spring my work will be published containing a full description. I shall be always glad to hear from you and render you any aid in my power. Meantime believe me to be,

Your friend and well wisher,

THOMAS DAVENPORT, Esq. CHARLES G. PAGE.

P. S.—I have kept a good account of electro-magnetic engines and I do not think that a horse-power was ever attained before my engine. Jacobi's great engine was about ⅛ horse-power, and so far as I can learn, was the most powerful ever made.

About the year 1850, Davenport became interested in the development of an idea which he had conceived, of producing music by electro-magnetism. The following notice of this invention appeared in a journal of the time:

[*From the Scientific American, April* 3, 1851.]

The Electric Piano.

Mr. Davenport, of Salisbury, Vt., we learn claims to have made an improvement in pianos, causing the musical chord by means of electric magnets to continue an equable and free vibration for any length of time. The perpetual and hitherto incurable defect of the piano-forte is the impulsive and evanescent nature of its tone, and though great improvements have been made upon it, and various devices have been elaborated to prolong its notes in some degree, yet the want of a sustained vibration is still an inherent defect in that beautiful instrument.

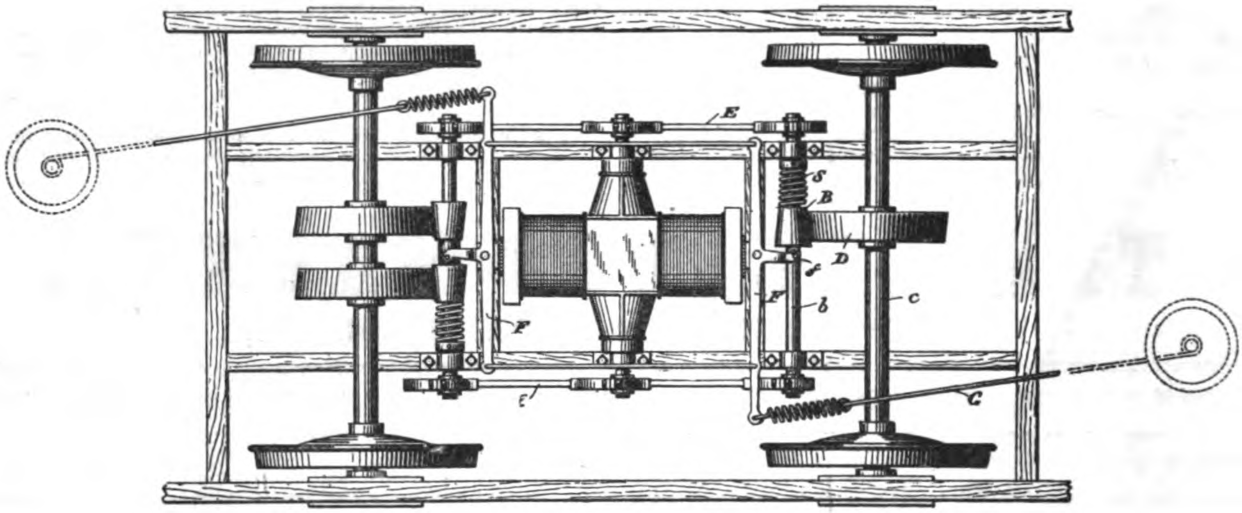
Davenport's work in this direction, which was attended with very satisfactory and successful results, was brought to an untimely end by his illness and death, which took place in the summer of 1851. It is my purpose to enter more at length into the history of his labors in this direction in a subsequent article.

BERLIN, N. H.—The Westinghouse Company is now installing a central station plant at Berlin, N. H., with the Westinghouse alternating current apparatus. The plant will commence operations with 750 sixteen candle power lights capacity.

McCARTHY'S ELECTRIC CAR GEAR.

AMONG the new devices designed to transmit the power developed by the motor to the car axle of an electric car we note that recently patented by Mr. L. A. McCarthy, of Brooklyn, N. Y. In this arrangement the inventor has sought to effect a simple arrangement by which the motor may be kept in constant operation, if desired, and thrown in and out of gear with the axle with the least possible jar, and thus to obtain efficiency with flexibility of connection. As shown in the accompanying engraving, the motion of the armature is transmitted to an intermediate shaft *b* by means of driving rods. Mounted upon this shaft is a movable cone pulley B placed directly opposite a corresponding friction pulley D, mounted on the car axle.

The pulley B is normally held out of contact with the pulley D by the spring S, and under such condition the motor runs free. When it is desired to start the car, the driver, by turning a lever on the platform, draws the rod G taut, which, acting upon the bell crank lever F, moves its short arm *f*, and presses the cone pulley B firmly against the pulley D. In this manner the motion is transmitted without shock and is under complete control of the driver.



McCARTHY'S ELECTRIC CAR GEAR.

THE PRACTICAL VALUE OF THE PHONOGRAPH.

The greatest feat of reporting that has ever been performed by the official reporters of Congress was that of preparing the Senate report for the *Record* Wednesday night, Jan. 14. The chief reporter is sick, and but two men were available to do the work. The Senate was in session for fourteen hours, all of which time was spent in an active discussion of the silver bill. It was after 12 o'clock at night when they adjourned, and during the session they had talked over 120,000 words. Two stenographers took the report, and, by dictating their notes into phonographs for typewriters to transcribe, they had all the copy ready for the printers by 8 o'clock in the morning, and the *Record* was on the desks of the Senators when Congress convened.

LAWS AGAINST THE EMPLOYMENT OF JUVENILE OPERATORS.

At its last session, the Georgia Legislature passed a law providing that in the future all railway telegraph operators must be not less than eighteen years of age before they can accept such positions, and, furthermore, they must pass an examination as to capability before the chief train despatcher of the road upon which employment is sought. Tennessee operators will push a similar measure before the Legislature of that State. They claim that the passage of these bills means the disappearance of the boy operator and a corresponding decrease in the number of accidents resulting from the employing of inefficient, immature and inexperienced railroad telegraphers. It would be well, perhaps, if every State should adopt such a law.

MR. W. H. McCULLOCH, manager for the Southern Telephone Co., at Greenville, Miss., has been promoted to the position of supervising auditor, with headquarters at Vicksburg. Mr. D. Thomas, of Memphis, succeeds him.

THE BUFFALO ELECTRIC RAILWAY.—THE LATEST DEVELOPED TYPE OF ELECTRIC STREET RAILWAY PRACTICE.

BY

C. J. Field

THE subject of electric street railway practice is of much interest at the present time, owing to the very rapid strides which are being made in this department. Owing to the rapid introduction of electric cars there has not been time to develop this line of the work as it went along to the degree of perfection now attained in electric lighting. As a result we have, in many parts of the country, engineering monstrosities in the way of station construction and line equipment. There has been no extended experience in the larger fields of railway work; therefore we have got to base and modify our experience on the more moderate sized plants, which, together with our knowledge in larger development of central station work in the light lines, enables us, with careful and at the same time progressive engineering to avoid some of the more marked errors which are apt to be made. Without entering further into the discussion of past experience we will take up a particular modern case in general detail, and try to show in what manner each part has been developed.

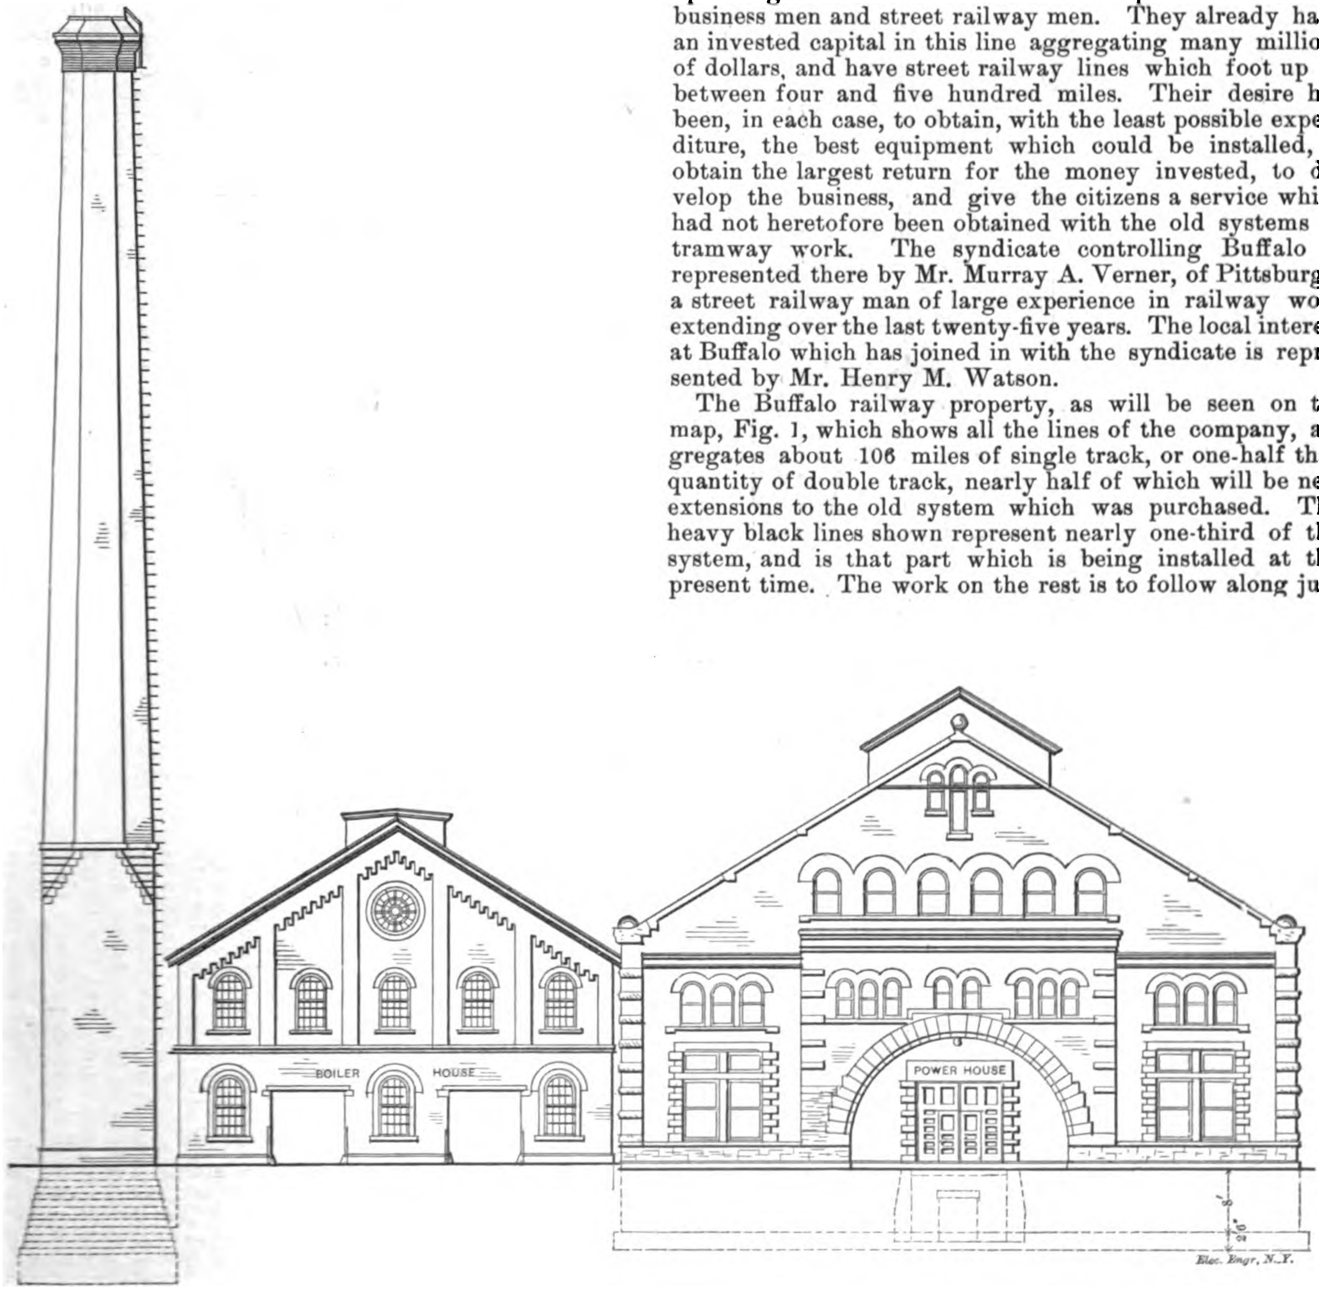


FIG. 2.—BUFFALO STREET RAILWAY POWER PLANT.—FRONT ELEVATION.
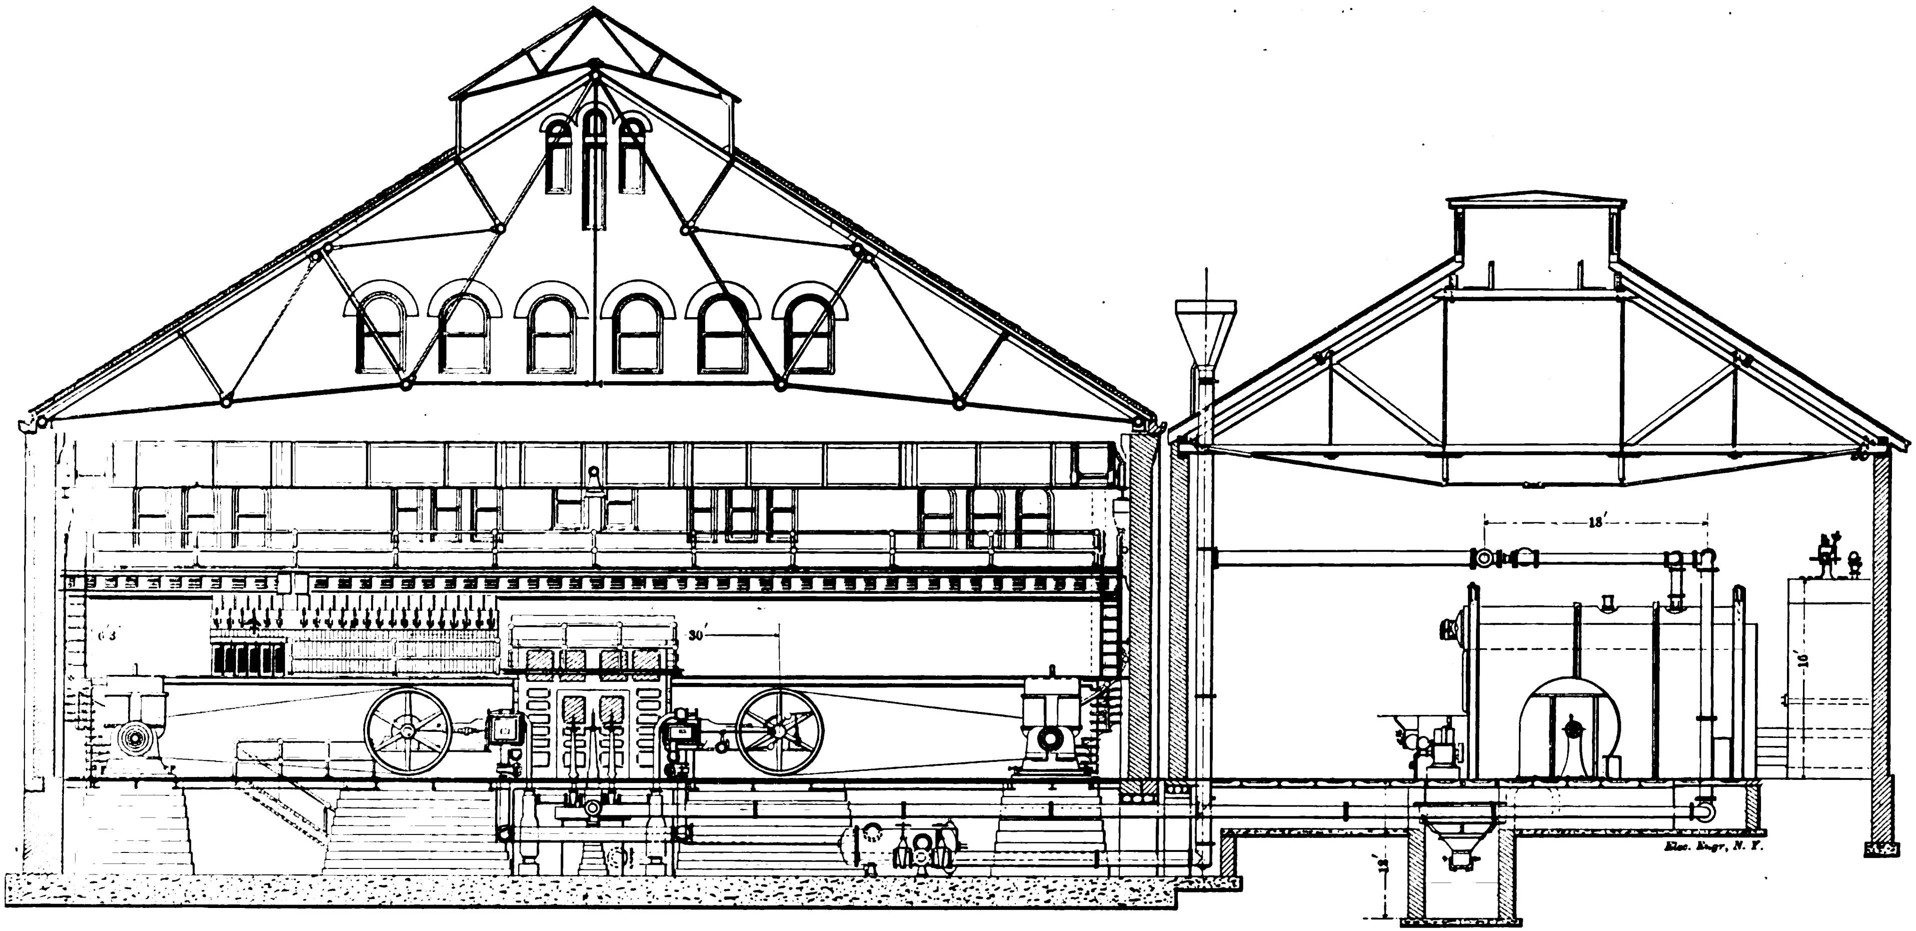
Designed and Constructed by The Field Engineering Co., of New York.

We have taken as an example the plant of the Buffalo Railway Company, which is the consolidation of all the street railway companies in Buffalo, N. Y., and is owned and controlled by one of the largest syndicates which is operating in this field and which is composed of bankers, business men and street railway men. They already have an invested capital in this line aggregating many millions of dollars, and have street railway lines which foot up to between four and five hundred miles. Their desire has been, in each case, to obtain, with the least possible expenditure, the best equipment which could be installed, to obtain the largest return for the money invested, to develop the business, and give the citizens a service which had not heretofore been obtained with the old systems of tramway work. The syndicate controlling Buffalo is represented there by Mr. Murray A. Verner, of Pittsburgh, a street railway man of large experience in railway work extending over the last twenty-five years. The local interest at Buffalo which has joined in with the syndicate is represented by Mr. Henry M. Watson.

The Buffalo railway property, as will be seen on the map, Fig. 1, which shows all the lines of the company, aggregates about 106 miles of single track, or one-half that quantity of double track, nearly half of which will be new extensions to the old system which was purchased. The heavy black lines shown represent nearly one-third of the system, and is that part which is being installed at the present time. The work on the rest is to follow along just as rapidly as it can be completed, and much of the track is already laid on the other part, which is shown in dotted lines on the map.

The number of cars to be operated on these lines, in the aggregate, will be about 300, which will be mainly 32 and 34 foot eight wheel vestibuled cars.

101132



THE BUFFALO STREET RAILWAY POWER PLANT.

FIG. 3.—TRANSVERSE SECTION OF PLANT.

Designed and Erected by the Field Engineering Co., of New York.

The power plant, as shown on the map, is located just above old Fort Porter on the Niagara river, from which water for condensing will be drawn. The plant is laid out for an aggregate and final capacity of 5,500 h. p.

The company's desire and purpose is to obtain in the line work, such perfection and development of the much abused trolley system as will remove from the biased public a prejudice which exists so largely over the country against this system; and this prejudice has been largely due to poor construction and the daily press. Buffalo is particularly adapted by location to have an overhead construction which will be an ornament to the streets, most of the streets radiating from a common centre and the curves in the line being very few; it will therefore present a view which can hardly be surpassed in long lines of well built construction which can be viewed for miles along streets without a single turnout.

About one third of the line will be centre pole construction, with tracks spread to six feet; the remainder will be cross-suspension. In all of the construction the best type of iron poles will be used. In order to make the line more secure, and remove any possibility of cumbersomeness in the overhead work, the feed wires in all portions of the city, except the outlying districts, will be run in underground conduits, the main trunk lines being run from the station in three directions, out of which branch lines are taken as the different systems are crossed, and divided up. By thus placing feed wires underground, we not only add to the reliability of the system in bad weather, but remove many of the prejudices against the same, leaving only the trolley and guard wires overhead. Having thus got a general idea of the system, we will now give a description of the power plant, the details of which are shown in the accompanying illustrations.

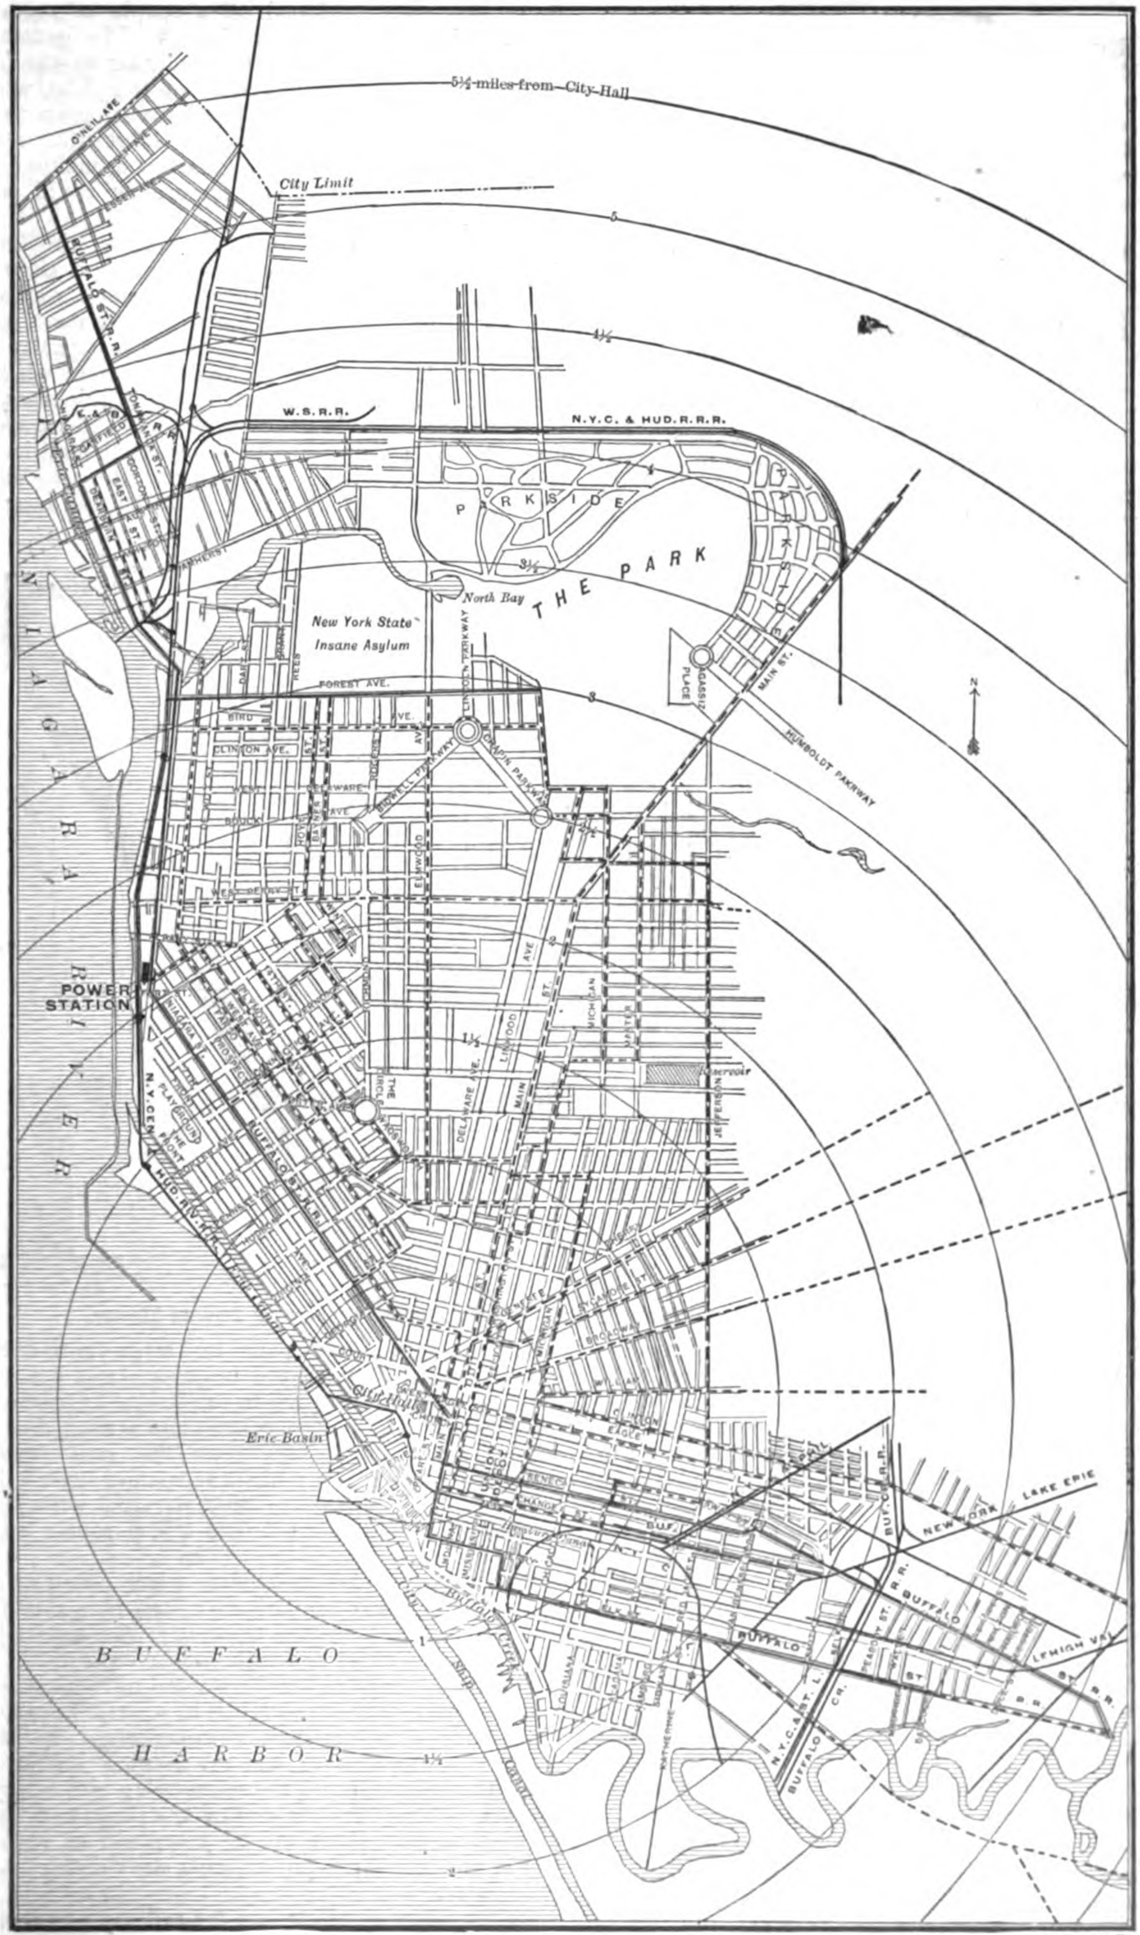


Fig. 1.—Map of Buffalo Street Railway System, Buffalo, N. Y.—Showing Location of Electric Power House and Lines.

Elec. Engr, N. Y.

BUILDINGS.

We have divided the power plant into two separate and distinct buildings, on account of the extended size of the plant, and as a matter of caution and better workmanship. The boiler house, Fig. 5, is a building about 55 x 180 feet, with one-third of the capacity installed at present, which consists of two batteries of Babcock & Wilcox sectional water-tube boilers, with an aggregate heating surface of about 12,000 square feet, and designed to stand a working pressure of 175 pounds. The boilers are fitted for natural and force draft, the stack put up at present being for this battery only; another one is to be built when the remainder is installed. As this plant will be run non-condensing, and therefore feed water will only be brought up to 120° by the exhaust before condensing, fuel economizers have been installed to further raise the temperature of the boiler feed. These are so arranged that the boilers may work either through the economizers, or pass by them in a separate flue, if desired; the blowers installed for forced draft will be used only when emergency may demand. For feeding the coal in the most economical manner for the kind used in this vicinity, Roney mechanical stokers have been installed. Underground conduits leading to the boiler room are used to convey the steam piping. Ash-pits are put under the grate bars, under which is a continuous ash run-way the full length of the building, for convenience in handling or moving ashes. The boiler house is of ample height and dimensions, so that no part of the plant is cramped or crowded in any way. The smoke flue is connected underground to the stack, which is outside the building. The general arrangement of the boilers, etc., is more fully shown on the plan view of the building, Fig. 5.

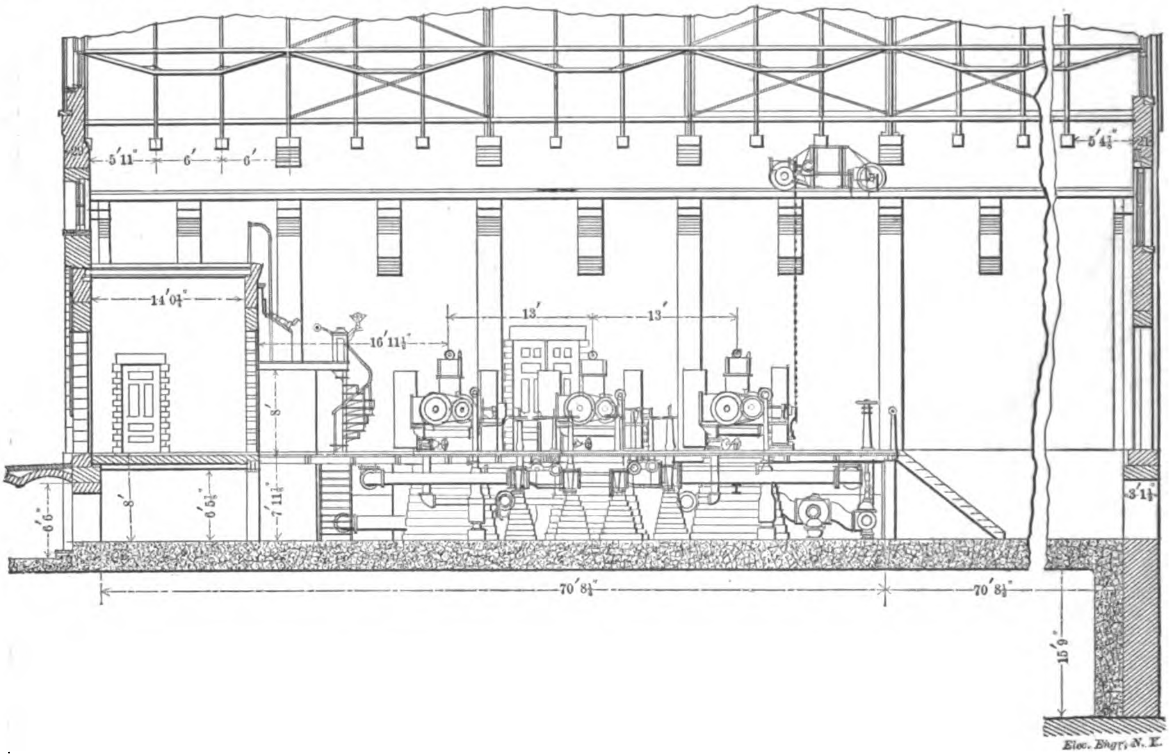

FIG. 4.—BUFFALO STREET RAILWAY POWER PLANT.—LONGITUDINAL SECTION OF POWER HOUSE.

The stack which is installed for this battery is, we believe, a model one, for its size and build, and presents, in the judgment of Buffalonians, the most handsome stack that there is in the city. The size of this stack is 150 feet flue from grate bars to top, with a cross sectional area of 50 square feet. The inside wall extends only 50 feet up the stack, and then there is an offset on the outer walls.

POWER HOUSE.

In the power house proper, Figs. 3, 4 and 5, we have the engines and generators and electrical apparatus in general. This building has inside dimensions of 86′ 11″ x 143′ 10″; in the front part are partitioned off a couple of rooms, one for office, and the other for workshop. The general idea of the architectural design of this building on the front, will be seen in the view of the front of the plant, which is illustrated in Fig. 2. The object here has been to obtain a building which would present a substantial appearance, and be appropriate to the neighborhood, making it at the same time as fireproof a structure as could possibly be obtained.

We have here presented, we believe, the largest and finest power room in the country, having a clear span the width of the building, with iron trussed roof overhead, and a traveling crane spanning the whole room and traveling the whole length thereof, and of a capacity to handle eight tons. The walls of the building are of plain selected brick, with the main walls 20 inches in thickness, and buttresses along the side at every 18 feet. There are no windows in the sides of the building at all, and, looking into the large room proper, only a few at the two ends at the top. Along the side and rear walls, though near the bottom, are placed in each panel two large ventilators for giving fair ventilation of the building from below, without creating any draft through the doors. Overhead, in the roof, we have the louvre so built and arranged as to afford ample ventilation from above. The roof truss is built completely of iron, on which the roofing itself is laid, composed of 3 inch Norway pine, covered with slate. The traveling crane is operated by a 5 h. p. motor, and has two hand trolleys.

The present power installation is composed of six units, consisting of cross compound engines furnished from New York by the Ball Engine Company; the capacity of these engines is 250 h. p., and each one drives a 225 h. p. Edison generator. The plant will be started off with this capacity, and the remainder, up to 5,500 h. p., will be added as required. The foundations, however, are only installed for the present installation, and the flooring is over this part only, the remainder of the room being left empty down to the concrete bed for the rest of the plant to be installed as desired, as this plant will be composed of eight units of 500 h. p. vertical compound, each one driving one or two generators.

In the selection of engines for railway power work there

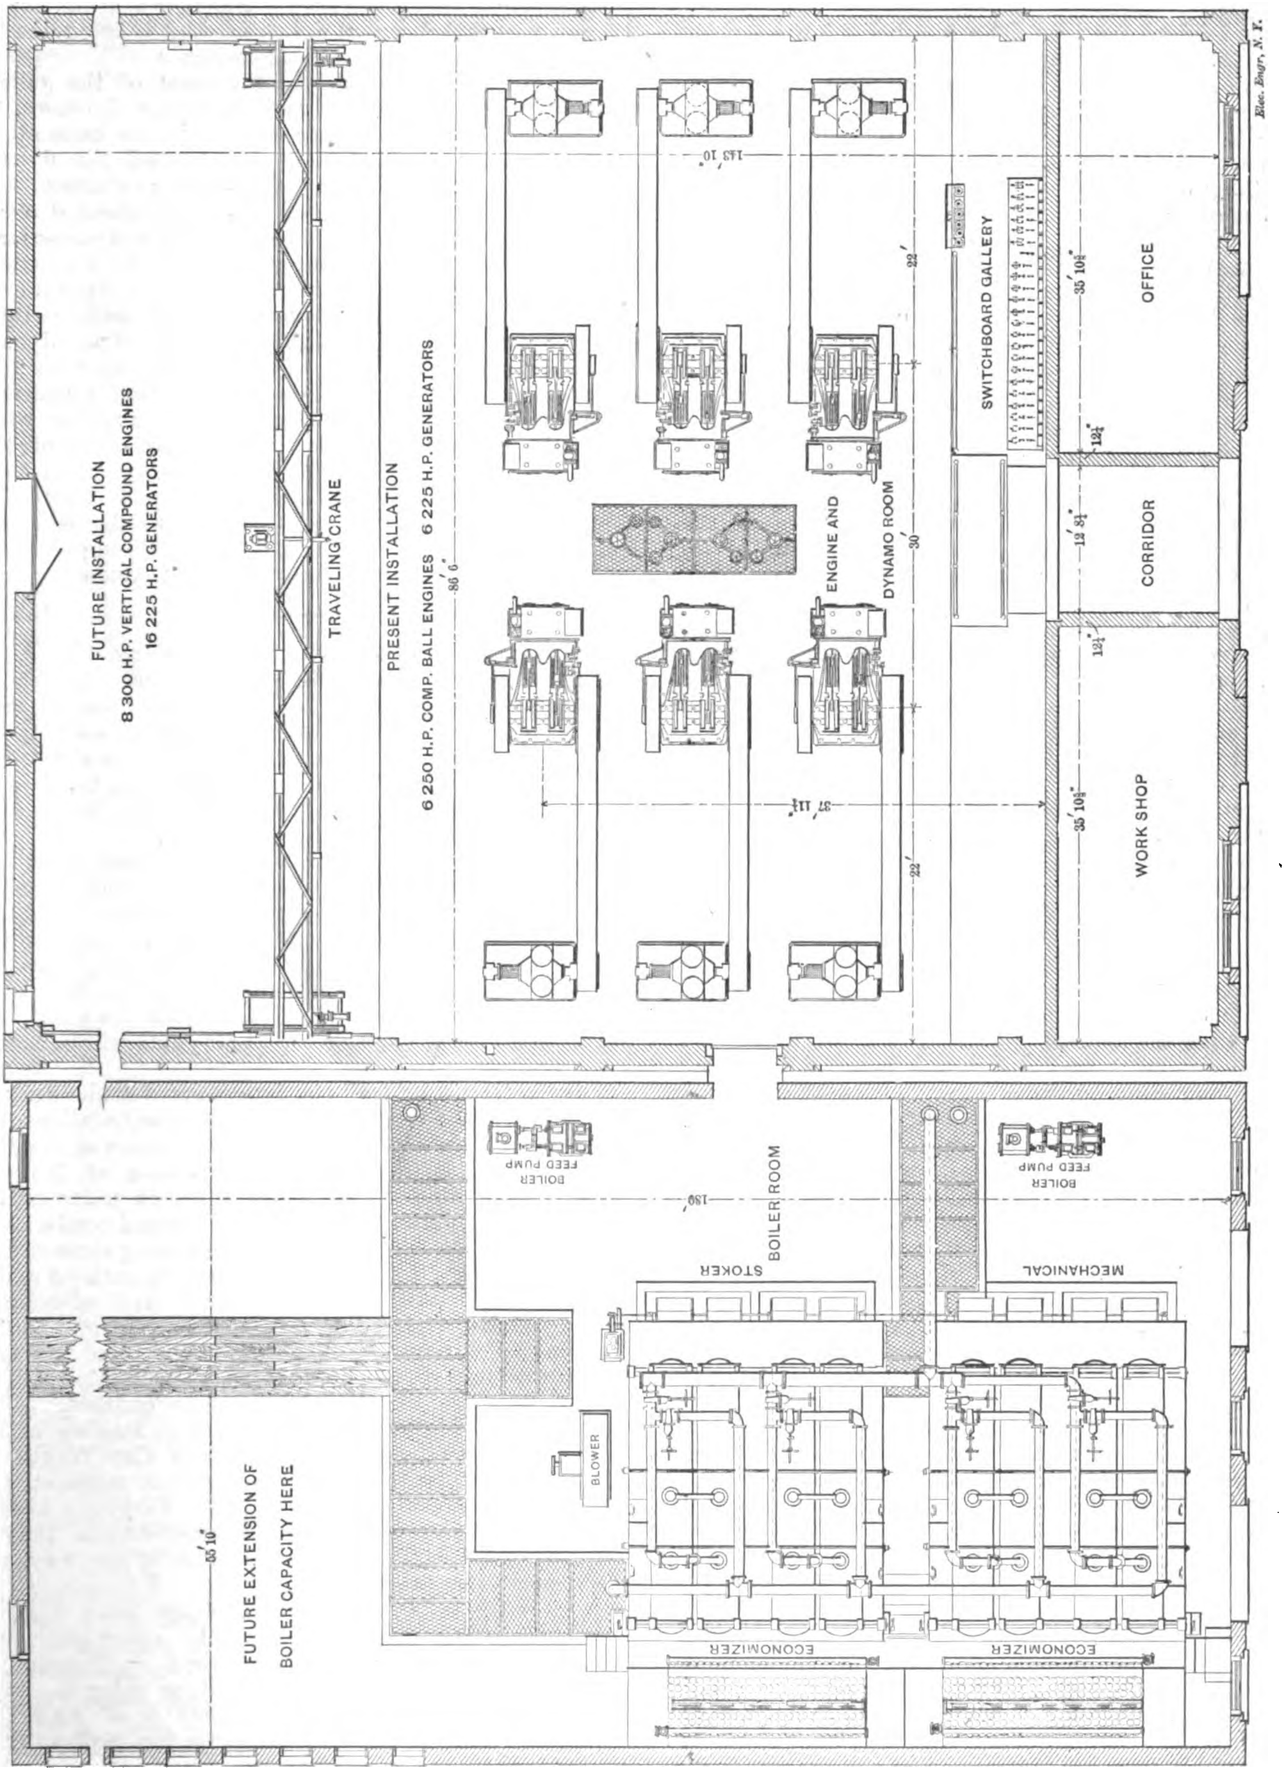

FIG. 5.—BUFFALO STREET RAILWAY POWER PLANT.—GENERAL PLAN.

Designed and Equipped by the Field Engineering Co., of New York.

has been considerable thought expended, as is well known, owing to the hasty work in many places, many errors have been made in the past in the selection and arrangement of proper engine capacity. The so-called high speed engines have, beyond question, in many places received a set-back, owing to some of the engine manufacturers not fully recognizing the needs and requirements of this service as distinguished from electric lighting work. Electric railway work is only to be compared with roll-train service in a rolling mill engine, and should be so designed, and built accordingly, to stand the continuous application and removal of its load. This means heavy, large bearings, strong moving parts, and extra heavy fly wheels.

All of the engines installed in this plant have fly wheels of 15,000 lbs., finished, running at 210 rev's., each engine complete weighing 50,000 lbs. Where high speed engines are built to stand the work in this way, we find them doing nobly, and giving good results and economy, unless we run across some cases where the people have got what may be called a compound craze. By this we mean a craze to install a compound engine, and operate it under such conditions that no economy is being obtained thereby. This is done where they are put in small plants and run non-condensing. Where compound engines have been installed this way, they have, beyond question, given poor results in the majority of cases.

What we are coming to on this kind of work is a vertical cross-compound automatic high speed or Corliss type of engine, and as soon as the electric manufacturing companies in this country have sufficient time to digest the subject, and work it out more thoroughly, the generators will be directly connected to the engine by being coupled right on to the shaft. We are, therefore, in this line of work, getting down to something more practical, and more specially adapted to the work. Where it is possible to obtain them, and get them well built, a unit consisting of one generator to one engine is sufficient, and, in fact, the division of units on any railway plant should only be such as to give economical working under the varying loads and conditions. Where we go up, though, to the larger units as here used, we practically remove one of the principal troubles in smaller plants, that of overloading and overcrowding the units of power.

The steam piping on this plant has been laid out in as complete and comprehensive a way as could possibly be designed, the object being to obtain entire reliability in the furnishing of steam at any and all times. It being impossible to suspend piping overhead, owing to the traveling crane, we have here, in piping under the floor, obtained a better and more perfected arrangement.

The steam piping is installed in duplicate, so that there there are always two sources of supply of steam up to each engine branch. On the iron floor plates shown between the engines on the general floor plan of the plant, Fig. 5, will be seen located the valves controlling the distribution of the steam from either source of supply to any engine, thus concentrating within a small area the valves for handling these. The valve stems, as will be seen, are extended up through the floor, and the handles brought within reach of the engineer standing on the engine room floor. In each engine branch from the main line to the throttle, is installed a water separator for preventing flooding of the engines under any possible conditions. The exhaust piping is arranged to pass through the heater and then to condensers, or free exhaust, as may be required at any time.

ELECTRICAL APPARATUS.

Across the front of the engine and dynamo room, on two sides of the entrance, as shown on the plan, and the two sections of the power house, Figs. 3, 4 and 5, there is situated the electrical arrangement on the electrical gallery. At this gallery the control and operation of the generators through switches and regulators, and also the control of all feeder lines leading into the conduit, is brought under the control of one man, and from this gallery he has a full and unobstructed view of the engine room, so that in any of his movements he can rapidly see what is being done on the floor while he is handling the switches.

First, at the left, we have on the front of the gallery, facing which a man looks down on to the dynamos, the regulator boxes and voltmeter stand. At the back of the gallery behind these boxes, are located the dynamo switches, and along to the right the feeder switches.

As the system to be operated is a very extended one, it was considered desirable to so arrange the dynamos and feeders as to give two different pressures to the outside system if desired. Therefore, above the dynamo and feeder switches is run a double bus-line, with switches placed between, allowing of the connection of any dynamo or feeder into either one of these two bus-lines; on the wall behind are located the dynamo, feeder and main amperemeters. We have, therefore, here a system which gives the greatest possible latitude for operating the plant, and facility for knowing what is going on in every part of it. Under the electrical gallery is located the cable shaft, down which the cables run to the basement, connecting with the dynamos, and also through a vault under the sidewalk with the underground system.

UNDERGROUND CONDUITS.

The underground conduits, as before mentioned, are installed here for the running of feed wires through the main parts of the system. Each line is so arranged as to have its own independent feed wires, one at each trolley wire. These feed wires are connected up to the trolley from the underground at every eight poles, or, in other words, about every 1,000 feet, all connections being made from man-holes.

Two styles of underground tubing have been used here, about one-half of each, namely, the wood pulp pipe of the Indurated Fibre Pipe Company and the cement-lined pipe of the Standard Underground Company. The conduits consist of from two to eight tubes, being 2½" or 3" in internal diameter. Man-holes are located 380 feet apart, thus making convenient distribution for drawing in of cables, and being so arranged that all joints will be located in man-holes.

The best insulated lead and jute covered cables are used throughout in the conduits. In the first installation of 15 miles of double track, there are about 10 miles of conduits, in which will be approximately 40 miles of No. 0000 cable, and to this must be added some 25 miles of feed wires of No. 000, in addition to the overhead conductors.

All the track work of the company is being reconstructed and built in the most substantial manner, with 56 and 60 lb. girder rail with a grooved tread, and with heavy Georgia pine ties placed 2½ feet between centres. Buffalo has a larger amount of asphalt pavement than any other city in the country, and on these pavements the rails are spiked directly to the ties, and the chairs omitted.

There are being built at present a large number of new cars for the company by the Gilbert Car Works and others, but, as yet, the company have not contracted for their electrical car equipments. The work has been so carried out, however, in the line construction that the company is not hampered in its selection in any way, as to the system to be finally adopted.

All the construction work which we have described above, including the buildings, stack, power plant complete, with the steam and electrical equipment, line construction and conduits, has been done under the supervision of the Field Engineering Company, of New York, acting as engineers and contractors for the Buffalo Street Railway Company. Their work covers all to be done in their line, which includes the equipment complete, except cars and track work. The designing of the plant by the Field Engineering Co. has been under the particular direction of Mr. E. F. White, mechanical engineer of the company, and Mr. E. J. Cook, constructing engineer. The construction work at Buffalo has been under the direct charge of Mr. J. B. Craven, one of their assistant engineers. The writer has had the responsibility of the general supervision over the different parts of the work.

We trust the above description, although incomplete, will give the reader a fair idea of the interesting class of work that has here been done, and we know of no work which develops the capabilities of the constructing engineer in this line to a larger extent than in carrying out a contract of this kind.

SOME PRACTICAL SUGGESTIONS ON OVERHEAD CONSTRUCTION OF ELECTRIC RAILROADS.

BY

In the construction of electric street railways, it is most essentially necessary that every detail shall be carried out in the most thorough and minute manner, and to all those parts, each of which has its own special function to perform, must the efficiency of the equipment as an aggregate be looked for. In discussing the best means of carrying out these details, the writer has classified the subject under the following heads:

RAILS.

All rails should be connected with railbonds of sufficient length to span the fish plate and allow a reasonable amount of slack so that the movements of the rail will not cause the bond to break. The rivet holes should be drilled at least two inches from either end of the fish-plate. On girder and T rail this hole should be drilled through the web of the rail, and on flat or tram rail through the flange, and countersunk so that the flange of the wheel will not reach the upset rivet. A rail bond 24 inches in length is usually sufficient for ordinary work. At frogs, switches, curves, or where short pieces of castings occur in the track, these pieces should be connected up in the same manner as the regular rail. It is also advisable to connect these small parts with a continuous wire to insure a good return circuit. At steam railway crossings the track should be connected in the same manner. On single track roads all rails should be cross-connected, in addition to regular bonding with a double headed bond, at every 60 alternate feet. No. 4 B. & S. soft-drawn copper wire is preferable for all railbonds, this offering less resistance than iron wire. On double track roads the same manner of cross-connecting should be observed as on single track, and in addition a cross connection of all four rails should be made about every 300 feet. It is conceded by a number of authorities that a continuous ground wire is not necessary to get a good return circuit.

POLES.

Natural wood poles should be at least 30 feet long for straight line work, with a diameter at the top of not less than 7 inches. They should be of cedar, Norway pine, or chestnut, as straight as possible and free from knots. Octagonal wood poles should be 7 inches in diameter at the top and 12 inches at the bottom, with an untrimmed butt of 5½ feet, which should be tarred before placing pole into the ground. Where wooden poles are used in centre pole construction, an iron shield should be placed around them for a distance of 5 or 6 feet upward from the grade line to protect them from being marred by wagons striking them. Lattice iron or girder poles should be 4 inches in diameter at the top, 10 inches at the grade line, and 11½ inches at the bottom, and at least 29 feet long. These, as well as all other iron poles, should be provided with a thorough insulated pole top. Corner poles should be heavier than side poles. If of wood, they should not be less than 8 inches in diameter at the top. Latticed corner poles should be 6 inches in diameter at the top, 13 inches at the grade line, and 14½ inches at the bottom. It is very important to have strong poles at curves and corners, and for that reason they should be extra long so as to allow of being placed 7 feet in the ground.

POLE SETTING.

For straight line work poles should be set 6 feet into the ground with a rake away from the track of at least 6 inches at the top. This rake will, of course, vary with the width of street, condition of soil, and weight of trolley

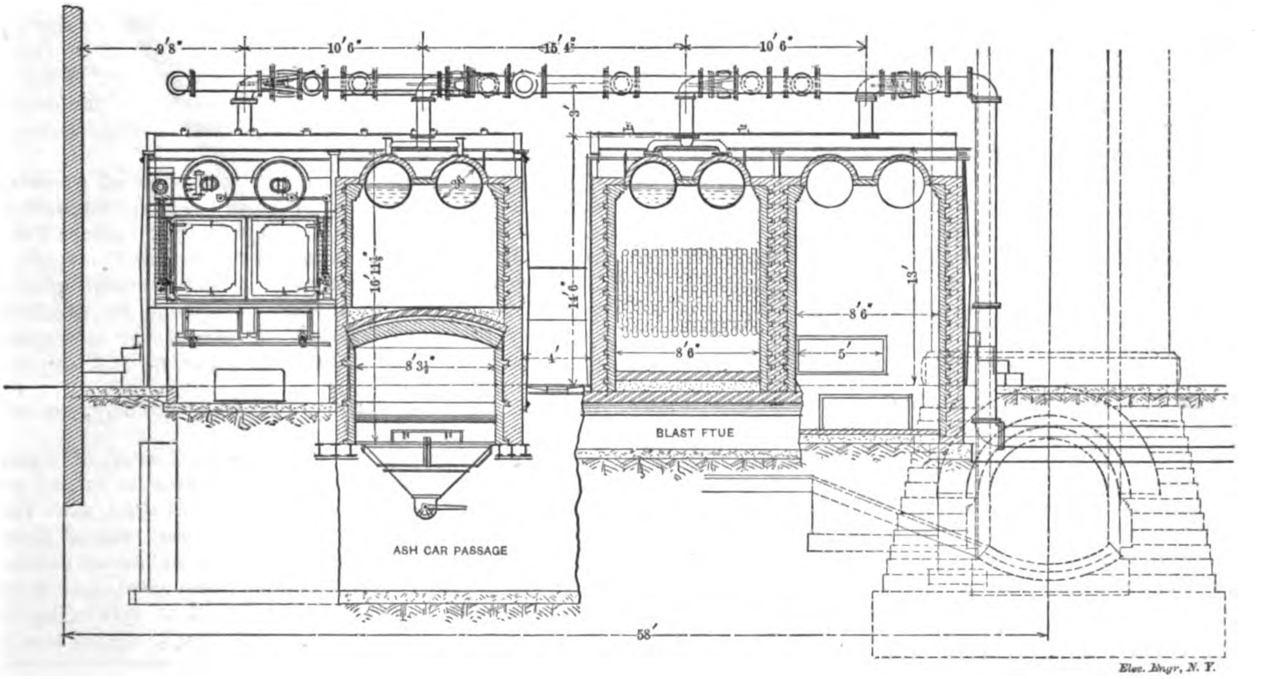

FIG. 6.—BUFFALO STREET RAILWAY POWER PLANT.—SECTION OF BOILER HOUSE.

wire. In setting iron poles a good cement concrete should be used. This concrete should be mixed with small stones and tamped well against the pole. The number of poles required for side construction is usually 88 to 90 per mile, making spans about 125 feet apart. This will necessarily vary with width of street and size of trolley wire.

INSULATORS AND FIXTURES.

Before setting wooden poles, a half-inch hole should be bored at a uniform distance from the top to allow for half-inch eye bolt or ratchet bolt. The use of a ratchet is advised, as it makes it very easy to adjust the trolley wire by simply letting out or drawing up on the ratchet. All insulating pins and brackets should be of best split oak or locust. At points where short turns in heavy feeder wires occur, an iron pin or wooden pin having a bolt through it should be used.

SPAN WIRES.

This wire should be ¼ or $\frac{5}{16}$ inch in diameter, of the best 7-wire steel strands. This is far better than solid iron wire, having much greater tensile strength, and being flexible. The pole ratchets to which these wires are attached should be placed on the poles at at a uniform height from the track, which should be such as to hold the trolley wire at least 18 feet from the track, allowing 2 per cent. of its length for sag.

TROLLEY WIRE.

This wire should be put up in as long lengths as possible. The starting and ending points of this wire should be securely anchored to a strong double span of stranded steel wire, attached to extra heavy end poles. This span should be thoroughly insulated from the poles by means of a heavy strain insulator. The trolley wire should be drawn to moderate tension only, allowing about 18 inches sag to every 125 feet. In cold weather it may be drawn somewhat tighter. Great care should be taken in handling this wire, so as to avoid kinks or scratches.

Curves should be completed as they are reached by the trolley wire. The trolley wire insulators should be clamped on, not soldered, after the line is in place, and all curves are made.

CURVES.

The poles used at curves must be set so they will not give when the strain of the line is placed upon them. The curve brackets should be placed at equal intervals, and it is advisable to solder the clamp to the trolley wire, so as to avoid any possibility of sliding. They should be so placed that the trolley wire may be exactly in line with the trolley on the car. To accomplish this, the curve bracket should be more or less inside of line vertically over the centre of track, the height of wire and radius of curve determining the position. The wire-holding curve brackets should be ¼ or $\frac{3}{16}$ inch 7-strand steel wire same as regular span wire. They should be well secured to an extra strong strain insulator, which in turn should be fastened to pole ratchet. It is advisable to use an insulator where curve bracket wires come to a focus, as this insures additional insulation from the pole. This is particularly the case where an iron pole is used.

FEEDER WIRES.

Great care should be taken in running feeder wires so that they do not become chafed, rubbed or kinked. Where they are run through trees, every precaution should be taken that no limbs or twigs are allowed to lie against the wire, as the swaying of the trees from the wind will eventually destroy the insulation. Where large limbs come in direct line of the feeder, tree insulators should be used.

Feeding in connections to trolley wire should be made through an insulated 7-strand steel cable, this cable serving at the same time as a span wire. To this cable can be attached an uninsulated hanger which at the same time holds the trolley wire.

GUARD WIRES.

Wherever there is danger of crosses with telephone, telegraph or other foreign wires falling on the trolley wire, guard wire should be used. This can be a solid iron wire suspended from either solid or stranded span wire, and insulated from poles by porcelain insulators. By paying special attention to the above points it is thought that the construction will be rendered more simple, and certainly more reliable and durable, giving that constant efficiency and practical working which is the aim of every electric street railway man to carry out in its entirety.

ON THE ARRANGEMENT OF VATS IN ELECTRO DEPOSITION.—III.

BY

C. O. Mailloux.

So much for the theoretical possibilities. Let us now consider the limitations which practice and commercial considerations would impose. The demonstration we have followed above has for its corollary the general conclusion that, other things remaining equal, the cost of power will vary in inverse relation with the *current density*. The practical question which intervenes here, is related to the fact that the character of deposit is to some extent affected by the current density. There is a wide range of current density within which the deposit is of practically constant quality. Any rise above the upper limit of this range gives a "sandy" deposit. On the contrary, if the current density falls too far below the lower limit, the deposit becomes crystalline and unequal, forming what is technically termed "nodules."

In electrotyping, the copper must be of good quality, and of a density midway between the two extremes is desirable. On the other hand, in refineries, where the object is merely to turn out refined copper for the trade, a very low density is allowable. The commercial question involved is related to the size of plant required and the quantity of metal that is in process of treatment at a given time. In the above case, the rate of deposition is reduced to $\frac{1}{n}$ in each vat. Consequently, to obtain n times the deposit, we need, as we found, n^2 vats, which means that not only the plant increases, in initial cost, but that the amount of metal under treatment, also increases, both in ratio n times greater than the rate of deposition. Hence, the practical limit to increased size of plant is soon reached. This is different for each case, and is fixed at the point where the saving effected in power by increasing the plant in the manner indicated, equals the interest on the outlay involved in the increased plant and the increased amount of metal that must be kept under treatment. Beyond that point it is better to increase the current density when increased output is desired.

The theory of the case shows readily, by a glance at equation (4), for instance, that it is important to reduce the electrolyte resistance to the lowest value consistent and compatible with working conditions. This is, unfortunately, what is seldom found realized in practice, merely owing to ignorance of the principles involved. No attention whatever, is usually given to the specific resistance of the solution, and the ratio $\left(\frac{l}{a}\right)$ which has such an important bearing on the economy of power, is left largely to take care of itself. The writer's experience is, that in most cases the depositing capacity could easily be greatly increased, and the *power* consumption *reduced*, by a little attention to these questions.

The question of dynamo efficiency has not been brought into the case in the above discussion. The equations deal, as we see, solely with the power delivered to the terminals of the vats. This may constitute 80, 90 or more per cent. of the energy generated by the dynamo, but it is plain that this percentage can, with a suitable machine, be kept the same for one vat or any number of vats. There is, apparently, much misapprehension as to the E. M. F. required in actual practice for depositing copper. The (London) *Electrical Review* bases its recent arguments on the presumption that 1 volt was the minimum potential difference that could be used per vat. The paper of Captain H. R. Sankey gives for the pressure used per vat, $C(r+R)$, 0.276 volt, or less than 10 volts for 35 vats in series. Gramme gives results showing 0.175 volt per vat, that is, 8.2 volts for 47 vats in series. As an illustration of the range of possibilities in this connection, the writer has deposited good copper with not over .15 volt per cell, while in other cases he has used as much as 5 volts per cell or vat. The first extreme represents *economy*, the second *speed*, of deposition.

There is an equal amount of uncertainty and vagueness as to the limits of current density. It is often stated that the upper limit of density is, for good deposit, about 18 amperes per square foot. The maximum, given by J. T. Sprague, is about 24 amperes per square foot. To illustrate further the wide range of possibility in this respect, the writer can state that he has deposited good copper with densities ranging all the way from a fraction of an ampere to more than *two hundred amperes* per square foot. The latter was not a mere laboratory experiment, but an actual practical result under commercial conditions and for a continued period.

The moral which the reader has doubtless inferred from the above observations is, that the cost of depositing copper will depend on the kind of copper, the speed at which it must be deposited, besides other commercial considerations. It may be well to add, that it will also depend somewhat on whether scientific or empirical methods prevail in working the particular process.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—XI.

(Copyright, The Electrical Engineer.)

BY

Herbert Laws Webb

It is important in testing a cable containing a large number of conductors, that the end of the lead be very carefully handled by the attendant who makes the connections, as, if the extreme end is touched or held frequently, the insulation is liable to become sticky and damp, causing an increase of leakage which would naturally be put down to the account of the cable, unless the lead were tried at intervals during the test, and any change in its condition noted and allowed for. A great deal of time also is consumed in changing the connections, unscrewing refractory nuts, tightening them up on the lead, etc. To obviate these difficulties a connecting clamp for joining on the lead wire to the binding posts of underground cable terminals has been devised, and is found to answer the purpose well, time being saved in changing connections, and the end of the lead being thoroughly protected. In Fig. 31, an illustration is given of this clamp in use; the clamp consists of a slit brass socket, the upper part of the socket being hinged and pressed towards the lower by a strong spring. The socket is attached to a hollow handle of hard rubber, and, the end of the lead being bent out straight, it is inserted in the handle, the end of the wire finding its way into a hole in the base of the brass socket, where it is held by a screw. The upper part of the socket or clamp is opened by pressing on the lever, which is faced with hard rubber, so that the attendant who makes the connections has no excuse for touching the lead at any uninsulated spot. In order to change a connection it is only necessary to remove the clamp from one binding-post to another; the pressure of the clamp on the binding-post makes a perfectly good connection, but the lead should be supported at a point near to the cable, or its weight hanging on the end of the connector will have sufficient leverage to force the spring back slightly, causing the upper jaw of the clamp to bear on the edge of the binding-post.

In testing a telephone cable it is advisable always to try the lead for leakage at the end of the test, and also to check the galvanometer constant; it is not unusual in buildings where machinery is sometimes running and sometimes stopped, for the sensitiveness of the galvanometer to vary, owing to the changed magnetic conditions. If the change is considerable and the deflections are regular, it will be noticed at once by the difference in the deflection; if the deflections are irregular the change in the galvanometer will probably be noticed by alteration of the zero, the spot sometimes going off the scale with a run without any apparent cause. After such an indication of altered magnetic surroundings a new constant should be taken at once. Such points as these, however, properly belong to each man's experience, and must be studied and provided for as they arise.

In testing for insulation the greatest degree of accuracy will be obtained by getting as large a deflection as possible; in this way closer readings can be made, and electrification or irregularities are more apparent. If a cable will give a deflection of 300, do not shunt the galvanometer so as to get a deflection of 30, under the impression that closer readings can then be made, as this is by no means the case. With short cables of high insulation it is necessary to employ a very sensitive galvanometer and a large number of cells in order to get a readable deflection, but if possible the battery should always be increased until a deflection is obtained that can be easily read, and that will allow of a certain fall due to electrification without getting within a few divisions of the zero mark.

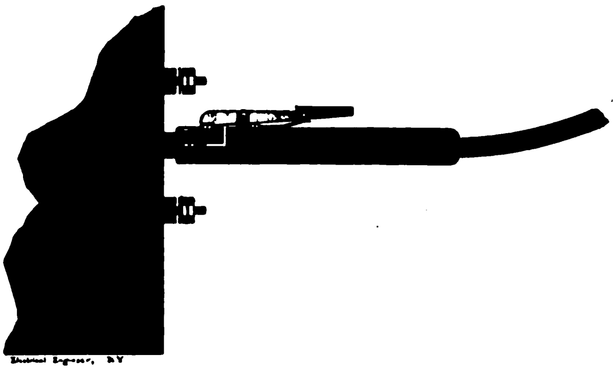

FIG. 31.—CONNECTING CLAMP.

It is erroneously believed by some that the insulation of a wire or cable differs greatly with the tension of the current, testing or otherwise, and that a wire which gives a certain insulation when tested with 100 cells will give a much lower insulation when tested with, say, 500 cells, and that, consequently, tests should always be made with the same number of cells. This, however, is not the case, or at any rate it is held not to be the case by the best authorities; if the insulating material is sound the resistance will be practically the same whether the test is made with 50, 100, 500, or 1,000 volts. Of course with a greater E. M. F. there is a greater current flow, and therefore the deflection will increase with the number of cells. Consequently more battery power may be added with a view to producing larger deflections without any fear of conflicting results from tests made with a lesser or greater number of cells.

It must not be imagined from this, that a test with very small battery power is a good indication of the condition of a wire or cable. Quite the contrary. A wire may show a very good insulation when tested with five cells, although it may contain a fault, or more than one, which the application of, say, 100 cells would reveal very quickly. In the case of a weak or faulty wire, increased E. M. F., therefore, makes a difference, as there may be weak spots in the insulating material which would stand a stress of 5 or 10 volts, but which would give distinct indications of their presence under a stress of 100 volts, and would probably be broken down altogether by 500 volts. For this reason a test made with a battery of only a few cells is valueless, and equally for this reason it is now the custom in many factories to test cables intended for high-tension circuits with an E. M. F. somewhat greater than that which will be used on them in actual working. That they have stood this test once, however, is no indication that they will last good indefinitely and under all conditions, and such wires, whether overhead or underground, should be tested periodically and a close record kept of their insulation resistance; in this way only can warning be obtained of impending trouble, and the economical stitch in time applied at the right moment.

A NEW LINE CONNECTOR AND JOINT.

In all classes of electrical work it is necessary that the line connections at the joints should be as solid as possible and offer a minimum resistance. It is naturally desirable, also, that the making of a joint should be accomplished quickly and inexpensively. The usual methods of soldering are open to objections on the two last points, and moreover in a soldered joint, there is apt to be more or less local electrolytic action or corrosion as two different metals are brought in close contact.

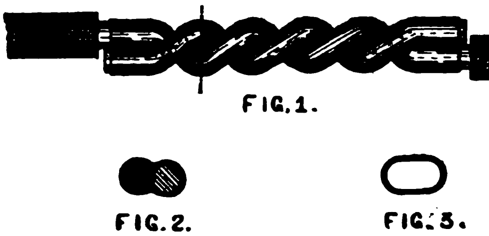

FIG. 1.

FIG. 2. FIG. 3.

A New Line Connector and Joint.

The new line connector invented by Messrs. W. A. Giles and A. M. Hunt, U. S. N., has been designed to overcome both these difficulties, and is exceedingly simple in its construction.

It consists merely of a short, seamless copper tube of oblong section, shown in the engraving, Fig. 3, large enough to contain the wires to be connected, which are inserted side by side.

The ends of the tube are then grasped by clamps, and twisted into the form shown in Fig. 1. During this twisting process, the wires are pressed and rubbed into metallic contact against each other, and the tube is drawn so tightly around them that the connection is practically a solid mass of copper, having even less resistance than an equal length of line wire. No soldering is necessary, and no local electrolytic action can therefore take place. Fig. 2 shows a section of a finished joint.

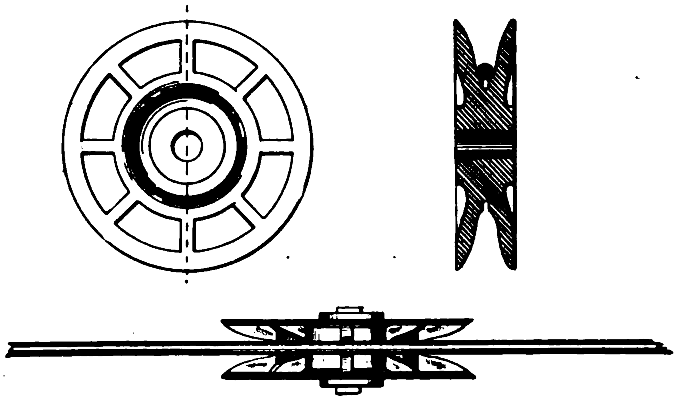
Wires of different sizes can be joined in the same way, as by sufficient twisting the tube can be made to conform to the shape of both.

The little device seems certainly destined to a wide application, not only in telegraph and telephone work, but especially in the distribution of current for lighting and power purposes.

Seattle, Wash. At a meeting of the Home Electric Co., Isaac Dobson, C. P. Stone and others were elected trustees.

THE LEWIS ICE-CUTTING TROLLEY WHEEL.

So much annoyance and loss has been experienced by the accumulation of ice on trolley-wires during sleet storms, that a trolley-wheel which also serves the purpose of an ice cutter, will be appreciated by the managers of electric railways operated on the overhead system. The accompanying illustrations show the Lewis trolley wheel designed specially for this purpose. As will be seen, the flanges of the wheel are provided with ribs which act as cutters and remove the ice from the wire in advance of the point of contact.



Figs. 1, 2 and 3.—Lewis' Ice Cutting Trolley wheel.

One of its principal advantages is that it need not be removed at frogs and switches. It is also apparent that the new arrangement can replace the ordinary trolley wheel permanently, if desired, as it makes an equally good contact with a clear line.

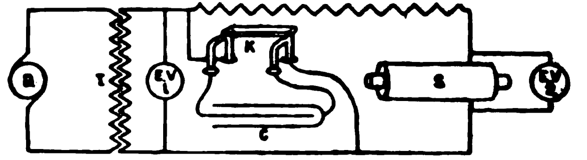
A very satisfactory test of this wheel was made at Seneca Falls, N. Y., during a severe storm on the night of Dec. 17, when the wires were covered with ice to the thickness of from a sixteenth to a quarter of an inch.

The device, we may add, is manufactured by the inventor for the present owners of the patent, the Seneca Electric Co., of Seneca Falls, N. Y.

THE RISE OF POTENTIAL DIFFERENCE IN THE DEPTFORD MAINS.[1]

BY W. E. AYRTON.

I am glad to see that Mr. Glazebrook holds the same view as that given by me to my students some little while ago on this subject. This view was, that when a transformer is used at Deptford to transform up the volts and another one at London to transform them down, the mere fact that the cable connecting these transformers had capacity was sufficient to cause the potential difference at London to be higher than the potential difference at Deptford. In connection with this suggestion some of the students at the Central Institution made a number of experiments last term, under the superintendence of Dr. Sumpner and Mr. Mather. The annexed figure explains



Demonstrating Increase of Potential.

---

[1] *Electrician.*

the arrangement of apparatus used by them for one set of tests, and with a certain rate of alternation, etc., they found on pressing down the double key, *K*, by its wooden cross-bar so as to connect the two coatings of the condenser with the two terminals of the secondary coil of the transformer, that while the potential difference measured by voltmeter $E_1 V$ (volts at Deptford) went up about 1 per cent., the potential difference measured by the voltmeter $E_2 V$ (volts at London) went up over 5 per cent. On raising the key, the potential difference at each end of the circuit went back to its original value, showing that the effect observed in this experiment was solely due to the addition of capacity to the mains.

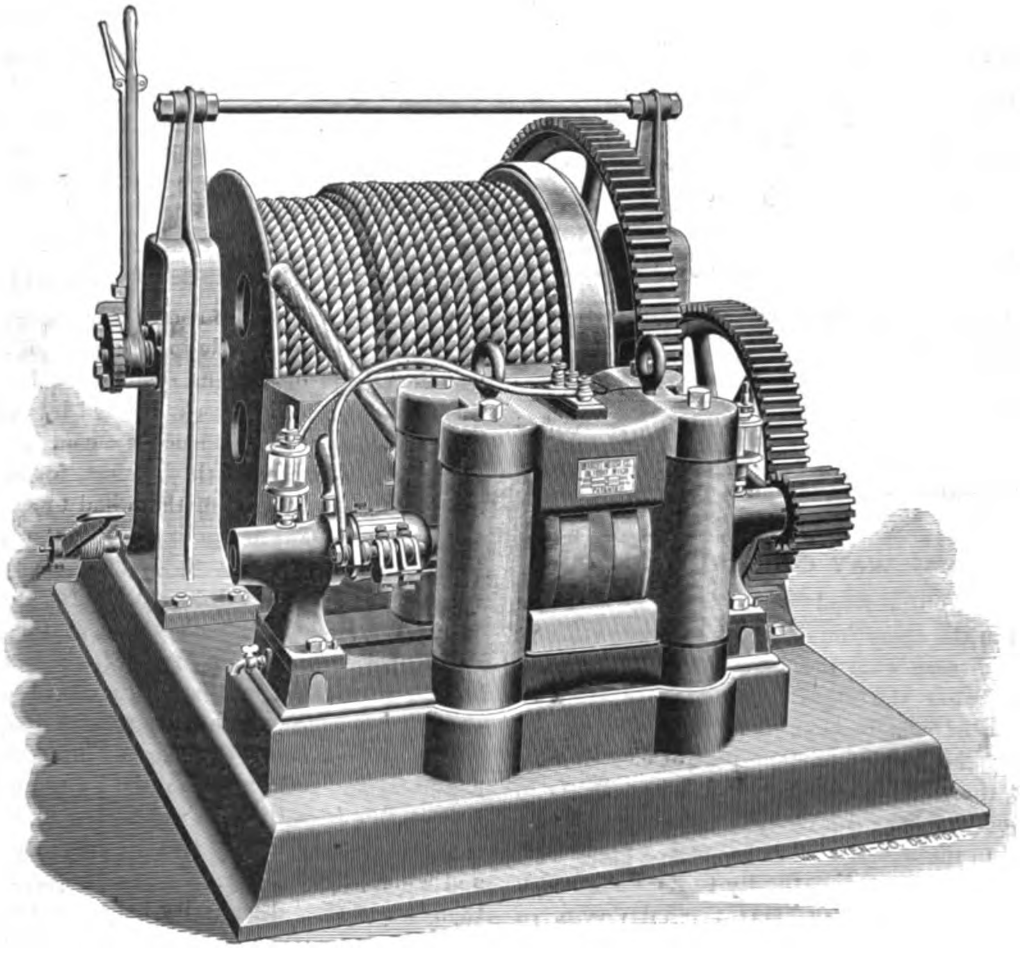
As the secretaries of the Physical Society tell me that they intend devoting one meeting early this next year *exclusively* to the subject of transformers, I will confine myself on the present occasion to the above brief description of this one experiment.

THE ELECTRICAL TREATMENT OF WINE.

For the past twelve months a small 8 horse-power experimental plant, due to M. de Meritens, has been in operation at the Bercy works of MM. Pollet, where M. de Meritens' method of treating wine by electricity has been exhaustively tested and pronounced satisfactory by competent authorities. The dynamo employed is a 25 volt alternator, having a frequency of 116. The wine to be treated by electricity with a view of increasing its "keeping" qualties is passed through a small tube containing a series of silver discs connected to the poles of the alternator. The wine as it flows through the tube is thus traversed by a rapidly alternating current, which it is supposed destroys the ferments. The experimental plant is capable of treating 22 gallons of wine per hour. The process has been tried on wines of all kinds, and the results have been most marked with the light Algerian wines, whose bad "keeping" qualities have hitherto prevented their exportation.

AN ELECTRIC ELEVATOR AND HOIST.

The accompanying engraving shows an elevator or freight hoist built by the Detroit Motor Co., of Detroit, Mich. This hoist is so designed as to bring the switch, the brake and the lever for operating the friction clutch convenient to the operator, so that he may not have to change his position. The side frames, containing the bearings are connected at the top by a stout bar, which prevents them from springing apart when the friction clutch is forced into place. The motor is provided with a raw-hide pinion and all the gears are of standard cut. The resistance box, with the switch for regulating the speed, is fastened to the iron bed plate. This machine is made in two sizes, of five and ten horse-power.



Electric Hoist of The Detroit Motor Co.

FARMING BY TELEPHONE IN IOWA.

Mr. H. C. Wheeler, who is one of the Republican candidates for the next nomination to the Governorship of Iowa, is a farmer of a new kind. Of the actual, downwright drudgery of farm work, Mr. Wheeler knows nothing. He is known in his own country as "the farmer by telephone." This title has come to him because the remote points of his broad acres are connected with his business office by wire, and, sitting in a comfortable chair before an open fire in winter and under an electric fan in summer, he can direct the movements of his hired men without further trouble to himself than the calling of a casual "hello!" Mr. Wheeler farms by telephone. Under these favorable conditions it is not singular that he likes it and that he finds it profitable.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XI. NEW YORK, JANUARY 28, 1891. No. 143

The application of science to the arts and industries is to but one purpose, to get the greatest return for a given amount expended.—David Brooks.

ELECTRIC RAILWAY CONSTRUCTION.

THE time is well at hand when it behooves those engaged in the operation of electric railways to look about them and discern what the experience of the past has taught and what the signs of the future are with regard to methods of construction to be adopted. To begin with probably the most important part of electric railway equipment, the power plant, we have no difficulty in recalling the time when the similarity in the general nature of the apparatus in the electric railway power plant with that used in lighting, led most naturally to its installation in much the same fashion. The same general design of high speed engine was employed which had shown itself so successful in electric lighting; but comparatively short experience has demonstrated that a good electric light high speed engine is not of necessity a good electric railway high speed engine. We believe that this is now gradually becoming recognized by competent engineers, and in proof of it reference need only be made to the admirable article by Mr. C. J. Field, descriptive of the power plant of the Buffalo Street Railway, which appears in this issue. Mr. Field's experience has proved to him that the electric railway high speed engine requires a strength and stiffness of parts which must be thoroughly capable of withstanding the shocks which the violent changes of load expeienced in street railway work bring upon it. To this must be added a heavy flywheel capable of storing a sufficient amount of power to accomplish smooth running even with extreme fluctuations. The problem is evidently a simple one which admits of an equally ready solution. The other departments comprising the power plant designed and carried out by Mr. Field are not less interesting and show an arrangement of boiler and electric plant which must develop a high efficiency in operation. The Buffalo Street Railway being determined to have nothing but the best in its work has very wisely started out at once with placing its feeders underground, and the wisdom of this step cannot be questioned by any one watching the course of events and noting the dislike manifested towards overhead wires. We are free to say that with the feeders and mains both placed below the surface of the street, the mere trolley wire will give rise to much less complaint than if the entire system were placed overhead. When we look back upon the work of the past few years in electric railroading and contemplate examples such as that now presented and under discussion, all fear as to the future is dispelled. It is seen that not only the electrician, but the shrewd capitalist, has become convinced that electric railroading is a profitable business and one in which he is warranted in investing millions in order to obtain the best and most economcial results.

THE HEALTHFULNESS OF ELECTRIC LIGHTING.

WE heard recently of some interesting though rather informal experiments made in a couple of Pullman cars to test the effects of various systems of lighting. Some of the officials going into a car lighted by one of the gas systems, sat down in the smoking compartment and shut it up. Their stay was of the briefest, for in a very few minutes even the strongest of them had to succumb to the heat and oppressiveness and to seek the outer air. A like test made in a compartment lighted by electric incandescents was attended by very different results, and it seems, might have been prolonged indefinitely so far as ill effect was concerned. This is not matter for surprise, however, and it may be matched by the experience of people who, being accustomed to the electric light, have had to sit in gaslit rooms, and who have been unable to endure the sense of heaviness and suffocation caused by the gas.

Such things as these do not figure in the estimates one sometimes sees as to the relative cost of gas and electricity, and which, by the way, are less frequent and more exact than they were. Electricity holds its own on economical grounds alone, if we are to believe the disinterested reports from innumerable mills, and other places of large and steady consumption, but the incidental gains are not to be overlooked. Thus, for example, the London *World* reports that a large hotel on Holborn has saved four years' expenditure on repairs and renewals of upholsteries and decorations. The General Post Office in London, moreover, reports that it saved $3,000 last year in sick leaves by the substitution of electricity for gas. The saving would evidently not stop there, for if those who would have fallen sick in an impure atmosphere were benefited by a cleanlier, more sanitary method of lighting, the toning-up effect on the others more robust must also have been felt in their brisker performance of duty.

The only offset to the gain with electric lighting is that which may come from the injudicious use to which people are sometimes tempted by the ease with which it can be brought into proximity to one's work. From what we have seen we believe that a nose attachment for bookkeepers, to carry an incandescent lamp, would be a great success. It is obvious that the heat and glare of a gas jet necessitate keeping it at a respectful distance, but in many an office the naked incandescent can be found swinging an inch or two from the head or hand of the clerk whose work it illuminates. No eye can stand that sort of thing long, and hence the complaints one hears occasionally. The best remedy lies, of course, in a regulation of the distance to which lights are swung or dropped and the employment of the admirable shade devices too well known to need naming. Another remedy not far to seek is a more judicious scheme of lighting for interiors. What is wanted is a distribution of light so even and well balanced that one is not conscious of the lamps but only of the illumination.

OVERHEAD LINE AND TRACK WORK.

It has been remarked elsewhere in these columns that the economical operation of the power plant must to a large extent determine the success of an electric railway, both financially and as a practical system of propulsion, but when we consider the subject in the light of an engineering question more particularly, the fact stands out prominently that satisfactory operation demands a system of track and line work that must be able to withstand all the influences that are brought upon it both by the operation of the road itself and by the elements. Here again it will be admitted that the work of to-day differs materially from that which was thought good enough at the outset. We have indeed been taught that a 35 pound rail will no longer do, but that a 50 to 60 pound rail is necessary to withstand the burden of electric cars and uninvited traffic. Practically the same increase in dimensions and weights has been proved to be desirable in the poles, span wires, trolley wires, and the many accessories which go to make up the complete overhead system, so that to-day electric railway engineers are in position to erect a line which may be guaranteed to stand intact against every ordinary wear which may come upon it. The article in this issue by Mr. A. H. Englund, detailing his experience as to the best type of construction to be adopted, is especially interesting at the present time when a large number of roads are contemplating equipment with the opening of the spring.

THE INVENTION OF THE AXIAL ELECTRO-MAGNET.

The fourth installment of Mr. Pope's biographical and historical paper on the Inventors of the Electric Motor, which appears in our present issue, is of unusual interest. The evidence which he brings forward appears to establish beyond peradventure that it is to Thomas Davenport that we are indebted for the application of the principle of the coil and plunger, afterwards christened by Professor Page the "axial" magnet, to the movement of machinery. This was effected by Davenport as early as 1838, and it appears that prior to 1840 he had built motors on this principle sufficiently powerful to drive a rotary printing-press. The caveat filed by Davenport in the spring of 1838, describing this interesting invention, which slumbered forgotten in the confidential archives of the Patent Office for more than half a century, until exhumed by Mr. Pope, is a document the immediate interest of which is only equalled by its permanent historic value. In addition to this, the correspondence between Davenport and Page upon the subject of the electro-magnetic engine, now for the first time made public, throws a flood of light upon the early researches of both of these able experimenters, and cannot but result in increasing our admiration and appreciation of the indomitable perseverance with which, in spite of limited means, imperfect knowledge, and countless other obstacles, their work was carried on, whereby the foundations of some of the most important industries of the present day were securely laid.

BUILDING FOR TO-DAY AND TO-MORROW.

Since starting its really magnificent campaign for rapid transit, the *Commercial Advertiser* has published a very interesting and ably reported series of interviews with electrical engineers and inventors as to the various problems connected with an underground electric road.

The effect of the unanimity of opinion shown as to the feasible nature of the scheme is seen in the immediate appearance of a plan for a whole series and network of such roads, to be built under the auspices of no less a railway magnate than Mr. Austin Corbin. Whatever may be the ulterior objects of this gentleman, his endorsement of underground electric transit has undoubtedly stamped the project as practical, in the eyes of the public, and has helped on the movement.

The latest interview, printed as we go to press, is one with Prof. Moses G. Farmer, characterised by all the glowing prophetic fervor and canny Yankee ingenuity of that Nestor of the electrical profession. He advises broad, generous plans not merely for to-day but "expecting the population of New York to outrun the present population of London and not need to have the 'darkest spot' in it." He offers the further suggestion that the tunnels may be used for large conductors distributing current for industrial power all along the line. To justify the faith that is in him as to electric traction, he mentions that 44 years ago he built an electric locomotive, equipped it with 48 Grove cells and carried passengers around a little track in the town hall of Dover, N. H. Now he sees the electric railroad running every twenty minutes between Great Falls and Dover, the scene of that early experiment. "I cannot think I am too much expectatious," says the venerable Professor.

An Eight-Column Snow Storm.

The newspapers of Monday morning were full of thrilling accounts of the great damage done by the wet snow storm of Sunday to the electric wires in this city. As many as eight columns were devoted to it by some papers, and the headlines were worth preservation as studies in the picturesque. It is true that a good deal of damage was done, and that among the chief sufferers were the long-distance telephone company's wires, which represent the finest construction in the country to-day—as does all their work. But one hunts in vain for any of the awful disasters that should attend this wholesale exposure of the public to such terrific dangers. The assertion is made that one man was hit on the head with a brick, but it still remains to be proved that a wire did it.

THE FORD & WASHBURN DYNAMO AND MOTOR.

The accompanying illustrations show the dynamo manufactured by the Ford & Washburn Electric Co., of Cleveland, O. As will be seen in Fig. 1, the bed plates and brackets are made in one complete casting. The magnet yokes are of wrought iron fastened to the bed plate, and the pole pieces are separate castings bolted to the magnet yokes. The field cores are wound on separate shells, and are interchangeable for all machines of the same size. The armature shaft is of steel and of extra large size.

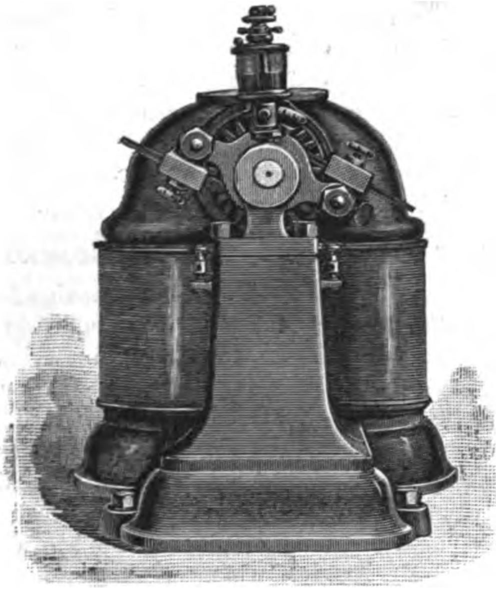

Fig. 1.—The Ford and Washburn Dynamo.

The special feature of this machine, however, is its self-ventilating armature. As will be readily seen from the engraving, Fig. 2, the discs, of which the armature is built up, are spaced, and the winding is separated, thus allowing a current of air to enter at the ends of the shaft, and having traversed the armature, to leave it radially, as shown by the arrows.

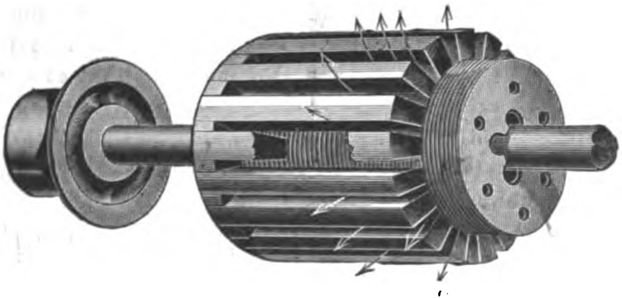

Fig. 2.—The Ventilated Armature.

Mr. Washburn, the electrician of the company, has also invented a storage battery, in which the lead plates are replaced by walled chambers, so constructed as to afford the freest circulation to the solution, the electrodes being separated by a porous non-conducting diaphram. The battery is exceptionally compact, and is claimed to be to all intents and purposes electrically indestructible.

Certificates for War Operators.—In the House of Representatives last week, Mr. Osborn called up and advocated a bill authorizing the issuance of certificates of service to telegraph operators who were with the Union Army during the war of the rebellion. Mr. Cannon inquired whether this was not a step towards granting these men pensions. Mr. Osborne gave an emphatic denial. The bill was passed, yeas 135, nays 82.

PRIORITY IN THE PRODUCTION OF ALUMINUM BY ELECTRICITY.[1]

BY PARK BENJAMIN.

In a dispatch dated Lockport, N. Y., Jan. 19, Mr. Eugene H. Cowles is reported as saying that the Cowles patents for the production of aluminum "cover the use of electrical energy in its broadest sense, whether it be used to produce heat or to act electrolytically." It would not be necessary to refute an assertion so incorrect as this were it not a fact that perhaps more inventors and more capitalists are now interested in the solution of the problem of cheap aluminum than ever before, and the fact of such a claim publicly made and left uncontradicted can only be to retard the work of the one class and to check the fostering interest of the other.

The earliest patent on the Cowles process is dated Aug. 18, 1885, and it describes a method of producing aluminum which consists in reducing an ore or compound of aluminum in company with a metal by means of electricity and in the presence of carbon, so that an aluminum alloy is formed, from which alloy the aluminum is afterward separated. The claims in the patent are to this process, and, so far from "covering the use of electrical energy in the broadest sense," the patentees themselves in their own specification say: "We are aware . . . that the alkaline earths have been reduced by electrolysis in contact with an alloying metal and plates of carbon or platinum, and the alloyed metals thus produced subsequently separated. We do not, therefore, claim the same broadly." This in itself is sufficient to meet the statement that Mr. Cowles is reported to have made. But perhaps a few words as to the prior state of the art may be added.

Aluminum was reduced from its chloride by electricity by Henry St. Clair Deville, the very eminent French chemist, in March, 1854, and was fully described by him in the paper presented to the French Academy of Sciences on Aug. 14, 1854, when he exhibited bars of aluminum thus made. Napoleon III. at once became greatly interested in the subject, inasmuch as he perceived many military uses of the metal; and he at once supplied the funds for further investigations by Deville. The first object made of pure aluminum was a rattle for the Prince Imperial, and the metal was exhibited at the Paris Exposition of 1855 as "silver produced from clay." In the same year with Deville, Bunsen described a similar process of electrolytic extraction in Poggendorf's "Annalen."

In 1859 Deville published his treatise "De L'Aluminium," and this work contains a complete account of his electrical processes, with pictures of the apparatus. Subsequent to Deville and Bunsen and before Cowles came the electrolytic processes of Le Chatelier, 1861; Monkton, 1862; Gaudin, 1869; Kargenbusch, 1872; Berthaut, 1879, and Gratzel, 1883, all of these people working on the electrolysis of fused aluminum salts. Besides these there were a large number of inventors who patented processes of obtaining aluminum by the electrolysis of aqueous solutions. Prior to the Cowles patent four United States patents were granted for the electrolytic extraction of aluminum, the earliest dated 1880.

The public may, therefore, understand that the "use of electrical energy in its broadest sense" for the extraction of aluminum does not belong to Mr. Cowles or to anybody else, and that it is free to any one to electrolyze aluminum solutions of fused aluminum salts, and to patent new processes and apparatus for the extraction of aluminum by any electrical means, subject only to the patents for the specific processess and apparatus now in force.

THE ELECTRICAL ENGINEERS AND THE "HENRY."

At the 53rd meeting of the Institute, held at the house, 12 W. 31st street, the evening was devoted to the thorough discussion of Mr. Kennelly's paper on "Inductance and Its Proposed Unit, the 'Henry,'" also the report of the committee appointed to consider the proper magnitude of the unit. The report of the committee was finally adopted, and is as follows:

At a meeting of the American Institute of Electrical Engineers, held September 16th, 1890, a committee consisting of Dr. Wm. E. Geyer, Dr. Louis Bell, George M. Phelps, Edward A. Colby, and Francis B. Crocker, chairman, was appointed to consider and report upon the best value for the "Henry"—the proposed practical unit of self-induction or inductance.

After careful consideration, the Committee has reached a conclusion and now recommends to the Institute the retention of the present value of the practical unit, which is 10^9 absolute units of inductance, usually expressed as a length equal to one earth's quadrant or 1,000,000,000 centimetres.

The Committee finds that this value is too high in some cases for convenience, as many practical measurements of inductance would have to be expressed in fractions of a henry. At the same time other practical values would often amount to a number of henrys, and sometimes to hundreds or even thousands of henrys. It is, of course, impossible to have a unit fit all cases, and in this instance it happens that the average practical inductance would approximate one henry in value. This may be considered fortunate. Small values may be conveniently expressed in milli-henrys, analogous to milli-amperes, etc.

---

[1] Letter to *New York Times* of January 21, 1891.

The Committee is of the opinion that even if the value of this unit (10^9 absolute units) had been much less convenient than it is, nevertheless it would probably be very unwise to change it, for the reason that it is derived from and related to the other practical units in the ratio of one to one, just as one ampere is equal to one volt divided by one ohm. To depart from this plan which has always been followed heretofore, would tend to destroy the harmony of the entire system of practical electrical units. The same fact made it necessary to define the farad as a capacity of one coulomb at one volt, although this makes its value so enormous that the micro-farad is always used in practical work. It appears, therefore, to the Committee that the value of the "henry" should certainly be fixed at 10^9 absolute units of inductance.

FRANCIS B. CROCKER, Chairman.

The paper and report were freely discussed by Dr. Cary T. Hutchinson, T. Wolcott, T. Reid, C. O. Mailloux, Prof. Crocker, A. E. Kennelly, C. Steinmetz, and others.

THE COMMERCIAL RATING OF ELECTRIC GENERATORS.[1]

BY THOS. G. GRIER.

GOOD engineering requires that specifications should have their aims, objects and purposes defined with accuracy. The generator of an electric light or power plant is one of its most essential features, and in defining or in rating its capacity we should do so in terms that have a tangible meaning.

The standard electrical units by which electric light installations may be specified are the ohm, volt, ampere, and candle-power, and in electrical power installations, the same, substituting the horse-power for the candle-power.

Instruments for measuring the ohm, volt and ampere, have been adapted to the necessities of practical engineering and when these three units are the basis of a specification it is with comparative ease that an expert can ascertain the correctness of the work.

In the majority of specifications and contracts, as now drawn, the capacity of the wiring will be for so many 16 c. p. lamps, or for so many h. p. motors, and the generator will be rated in so many 16 c. p. lamps or for so many h. p. motors. This use of the units candle-power and horse-power virtually means nothing.

The arc lamp of so many nominal candle-power is another unit which means nothing when applied to the capacity of the machine.

The candle-power unit is, in a measure, open to criticism on the ground of inaccuracy, but in this discussion the discrepancies that may exist in the several standards are not the points to be considered. The candle-power unit is a unit of light. Our generators do not produce light, but electrical energy. Our arc and incandescent lamps convert the electrical energy into light and heat. The horse-power is the unit of power. Our generators do not produce the power, but our motors utilize the electrical energy and convert it.

Before considering why we should not use the terms, candle-power and horse-power, in rating our generators, even though these terms are perfectly correct, we will discuss the converting apparatus, that is, the incandescent lamp, the arc lamp and the motor.

The incandescent lamp being an apparatus for converting electrical energy into light with an unfortunate side product of heat does not give back 100 per cent. of the electrical energy as light, nor does the proportion that produces light and the proportion that develops heat vary in the same ratio under different conditions. Lamps are in use to-day that vary in the consumption of energy per candle-power produced from 3 to 7 watts, and even as low as 2 watts has been claimed. This variation in the energy when the lamps are of the same voltage means a variation in the amount of current necessary to produce the equal amount of light. Recent experiments made upon lamps bought in the open market show conclusively that lamps of the same rated voltage and candle-power are not uniform. Here are a few instances of the variations of the amount of current required.

1. Twenty lamps, 10 each of two different makes, were placed upon ordinary commercial meters and were burned for the same length of time. To eliminate the errors of the meters they were transposed so that each set burned an equal time on each meter.

The result of the experiment showed that there was a difference of 27 per cent. in the amount of current consumed between the sets.

2. Another station tried the same experiment using one set of lamps of a different make from that of the former and one set of the same make. The result of their experiment was a difference of 22 per cent.

3. A station operating some 700 lights had a number of the nominal 16 c. p. lamps that were in use tested and found the candle-power to range from 17 to 22. On discovering this, nominal 10 c. p. lamps were used and called 16 c. p. As the current was sold by meter, the customer was in no way injured by the substitution.

4. A number of large lamps were tested and nominal 100 c. p. lamps were found to give from 44 c. p. up to 110 c. p.

5. In December, 1890, tests were made on four different makes of lamps. All the lamps were marked by the manufacturers at the same voltage and all were nominal 16 c. p. lamps. The tests showed a variety of candle-powers ranging from 11 up to 24 and efficiencies from 2.46 watts to 4 watts per candle-power.

6. A large lamp of new make of nominal 150 c. p. gave an efficiency of 2.4 watts per candle-power. As this was the most efficient of any lamp tested it has been placed on the circuit of a central station and is undergoing a life test.

These experiments are of considerable value in this place as proofs of the desired end in view, as they show that when capacity is given in candle-power, it means only an approximation. We should not, however, draw conclusions as to the real commercial value of the lamps tested. The durability of a lamp is a most important factor, and without a test as to the life of the various lamps and a mathematical equation being deduced that would include life, efficiency and cost of lamp, no actual commercial conclusion should be drawn. It is a well-known fact that the life of a lamp is dependent upon the efficiency at which it is run. A lamp can be made to produce light commercially at an expenditure of energy varying from 2 to 7 watts per candle-power.

The factors that govern the efficiency at which the lamp should be run are, the cost of producing the electrical energy and the cost of the lamp. From this view of the matter, even though the lamps were uniform, it is possible to have conditions wherein would exist a difference of over 100 per cent. in the amount of current necessary to produce equal amounts of light.

When a specification requires that an incandescent dynamo should have a capacity of 100 16 c. p. at 110 volts, what does it mean? Must the machine be capable of producing energy sufficient to operate lamps at 7 watts or but two watts per candle-power? Must it develop 30 amperes or about 102 amperes? Either machine is within the range of the specification, the efficiency of the lamps governing entirely the size.

If nothing further than the capacity in candle power is specified what right would the purchaser have to grievance, or redress, if the machine of the smallest limit, that is, 30 amperes, were sold to him as a 100-light machine, his lamps requiring more than 30 amperes?

The arc lamp is also an apparatus which converts our electrical energy into light and heat. Its efficiency, when the lamp is well adjusted and cared for, should not vary to any great extent. Bad adjustment is a fruitful cause of poor efficiency and good adjustment can not be maintained without good regulation. To measure the candle-power of an arc lamp is not the easiest matter in the world and for one to attempt to judge by the eye is an absurdity. In tests that have been made on arc lamps the results were from $\frac{7}{10}$ of a horse power up to $1\frac{4}{10}$ horse power per lamp of 2,000 candle power, so called. These figures were based upon the difference between the total horse power exerted by the engine and the horse power of the engine running empty, and the belt thrown off the dynamo.

As the actual candle power of the lamp could not be measured it remains still a matter of conjecture whether the machines were really of so many 2,000 c. p. lamp capacity.

The electric motor is another apparatus for transforming electrical energy into different form. The efficiencies of the various motors on the market vary from 90 odd per cent. to as low as 50 per cent. and perhaps lower. Their efficiency also varies with their speed and load. The generator for a 10 h. p. motor could mean a machine capable of generating anywhere from 11 h. p. up to 20, depending entirely upon the economy with which the electric motor utilizes the energy supplied by the generator.

The question of rating the machines in the units which measure the work of another piece of apparatus is merely rating the machine upon a variable standard, that is, the efficiency of another machine. We do not rate our engines in the capacity of the dynamo but upon a unit of its own, the horse power giving the speed and pressure at which this horse power is developed. The boilers, however, are rated in the unit horse power, which unfortunately is as great a mistake as the rating of dynamos or generators in any other unit than that of the form of energy which is directly produced by them.

The transformation or the conversion of any form of energy to another must take into consideration the efficiency of the conversion. In transmitting energy from the point of production to the point of consumption a loss is entailed. To convey electrical energy for light and power we use a metal conductor. The size of this conductor is not dependent upon the amount of horse power developed or the amount of candle power developed, but upon the amount of current transmitted and the amount of pressure. It is within the limits of possibilities that the current to develop the same amount of light or power may be, in one case, double what it would be in another, owing to the difference in efficiency of the converting apparatus.

---

[1] A paper read before the Chicago Electric Club.

Another point to consider, besides the efficiency, is the resistance in the conductor. In some cases where fuel is extremely cheap a large percentage of the energy may be used in transmitting the power and, consequently, the generator would require an increased capacity in proportion to the percentage that is lost.

Tables for the use of wiremen have been prepared by the various companies, and while speaking of the generator, it is just as well that attention should be called to the tables. The units used as a basis for their determination are the horse power and the 16 c. p. lamp. It is apparent that a wire to carry a 16 c. p. lamp, or a horse power, with a certain percentage of loss, does not even mean an approximation, the variable conditions that exist giving the expression only a very general meaning.

The lamps or the horse power are assumed to take a certain amount of current and though the calculations are correct, the entire table depends for its accuracy upon how near the assumption approaches the actual efficiency of the apparatus used.

The capacity of the generators should be specified that measure the energy in the form in which it is developed. Dynamo electric machines develop or produce electrical energy measured in volts and amperes. The carrying capacity of wires for the transmission of this energy depends upon volts and amperes. The candle power and horse power have nothing to do with it. Electrical generators should have their capacity specified in volts and amperes or in watts giving the pressure in volts at which this specified power is produced. The sizes of the wires should be determined upon the basis of amperes and volts, stating the percentage or number of volts lost in transmitting the current. The English manufacturers give the capacity of the dynamo in watts and a purchaser, even though he be ignorant of the first principles of electric machinery, could, with little trouble, determine whether he had received the dynamo capacity he had paid for. But were the rating in candle power or horse power the results could not be so satisfactory.

The Edison Co., in the United States, and several others of the larger electric manufacturing companies give the capacity of their various generators in watts but the agents and contractors seem invariably to overlook this and propositions and contracts are drawn up with the generators rated in the indefinite terms, horse power and lamps or candle power.

Why the Americans have adopted tho candle power and the horse power as a basis of rating electrical machinery and the compiling of wiring tables is perhaps apparent to many, and the reasons were no doubt at one time good. It is, however, obvious that this general use of these technical terms is entirely wrong and the electrician must be the means of reorganizing the system. The tendencies are in the direction of this needed reform but the change cannot be too rapid.

The fundamental principles of Ohm's law are thoroughly familar to the intellegent workman and the sooner our calculations are confined to mathematical accuracy and our generating machinery rated in the proper units the better for the electrical business.

NOTES ON THE ELECTRIC RAILWAY: HISTORICAL, STATISTICAL AND TECHNICAL.[1]

BY F. L. POPE.

FEW people have any conception of the enormous extent of city and suburban traffic in the cities of the United States. A few statistics are more impressive than pages of rhetoric. The official returns show that during the year ending Sept. 30th, 1889, the 110 street railways in the state of New York carried over 686,000,000 passengers, or 100 times the total population. In New York city alone the surface and the elevated roads carried together about 400,000,000. In Boston, 100,000,000, and in Philadelphia, 150,000,000 passengers were carried. In fact, statistics indicate that the street railways of the United States carry something like twice as many passengers as all the steam roads, and moreover, it has also been found that the number of passengers increases from year to year in a much greater ratio than the population, which means, not only that more people ride, but that the same people ride more frequently each succeeding year.

The transportation of this enormous number of passengers; probably not less than four or five billions, taking the whole country together, with safety, comfort, speed and economy, must be recognized as an undertaking of the most gigantic description. It is well worth our efforts to carefully consider the best means by which it can be accomplished. No work has ever been done by the inventor, the engineer or the electrician, of such immediate and direct benefit to the masses, as that which has to do with the subject under consideration.

Mr. Pope here dwelt briefly on the nature of the three methods of overhead, conduit and storage traction, and then in a very interesting manner gave the details of the work of Thomas Davenport and Page, exhibiting a copy of *The Electro-Magnet*, a little weekly paper printed by Davenport in this city just fifty years ago. After pointing out the impossibility of achieving any great result with chemical batteries as the source of power, Mr. Pope came to the invention of the dynamo, the discovery of its reversibility, and the dawn of the modern era of electric power transmission. He then called attention to the very early work of Stephen D. Field, and to that of Joseph R. Finney, who brought out his overrunning trolley at Pittsburgh in 1882. Mr. Field had in his original plans proposed the use of a conduit, and that method was to-day being eagerly pushed to perfection.

Mr. Pope then dwelt upon the many desirable features of storage traction, but showed that the main objection was a financial one, a storage car mile costing 10.6 cents, or about the same as horses, while the overhead system reached only about 5.09 cents per car per mile. As to the results of storage battery operation, Mr. Pope reviewed the expert tests made by himself in 1886, for President Whitney, of the West End road, of Boston.

Coming to the question whether electric railways are dangerous, Mr. Pope said:

With a view of getting at the actual facts in the case, the *Boston Advertiser*, a few months ago, sent out a circular letter asking information from every city in which electric railways are in actual operation, from Portland, Me., to Galveston, Tex. It was asked what system was used in each place; whether there had ever been loss of life or injury from the wires; whether there was any serious objection on the part of the public to overhead wires, and what was the general opinion in the locality as to the effect of the introduction of electricity upon the street railway service? Replies were published from 64 cities and towns. All but four of them were favorable. Not one solitary instance of accident or serious injury from electric currents was reported. One of the objecting places was Newport, R. I., where it seems the "upper ten" strenuously opposed the introduction of anything that would popularize riding on the streets.

An extraordinary amount of nonsense has been printed and talked in respect to the alleged dangers of both electric light and railway wires. The public have been needlessly alarmed by the exaggerated statements of interested parties, but, nevertheless, the danger is so small, as a matter of fact, that the actual figures are almost astonishing. Most of the accidents which have been reported occurred in New York city. Yet the statistics show that in 1889, out of 1,467 deaths in New York city, by accidents of various sorts, only *nine* were due to electricity, a considerably less number than were killed by being run over by horse cars. Not a single death was recorded in Boston, although there are perhaps more wires there in proportion to the population than in New York. There are in the six New England States nearly 140 arc light stations, burning over 20,000 arc lamps and distributing 30,000 horse-power of electricity through the streets of the principal cities and towns. During the last ten years, so far as I can ascertain, there have been but *five* deaths from electricity; four of these were employés of the lighting companies, and one was a careless boy who climbed upon a shed and took hold of a wire. During the same ten years the steam railroads of New England have killed 2,339 employés and 2,902 other persons! 5,241 against 5. Not only is electrical power far less dangerous than the same quantity of power used in other industries, but it is relatively safer, as the few accidents that do occur are among the employés. These remarks refer to electric wires in general. Now as to electric railway wires:

I believe that it is an incontestable fact that not one single man, woman or child has ever been killed or even seriously injured by a 500 volt current, which is the highest pressure ever permitted upon electric railway wires. Every alleged case of accident by railway wires has, upon investigation, proved to be either without foundation, or to have been caused by an electric light current. When we consider that shocks have been experienced by men, women and children; persons of all ages and all sorts of physical conditions, sometimes for a period of several minutes, experience seems to warrant the positive assertion that the electric railway current is not dangerous to human life, and that we may dismiss that question from further consideration.

Many persons are alarmed at the vivid flashes of light which are often seen at night beneath the wheels of an electric car, and at the point of contact of the trolley wheel with the overhead wire, and are under the impression that they must indicate a very dangerous electric pressure. Such, however, is not the case. In an electroplating establishment at Ansonia, Conn., I once saw a workman accidently set a tin pail filled with water upon a pair of electric conductors near the dynamo. The pail instantly disappeared, being not merely melted, but being converted into metallic vapor, with a terrific flash which illuminated the whole building with a dazzling and instantaneous radiance; yet the current which produced this startling phenomenon was of such low pressure that it was impossible to detect its presence by the sense of touch, even by applying the hands directly to the bare conductors.

The average speed of the horse car is about six miles per hour. The question is sometimes asked: How fast may electric cars be safely run in a city street? One fact within my own knowledge will go far to answer this question. There is a heavily traveled street in Pittsburgh only 36 feet wide, containing a double-track cable road, which leaves not more than nine feet space on each side. At first the cable cars were run at the rate of seven miles per hour; afterwards the speed was increased to nine and one-half miles per hour. The records show that there are not so many accidents under the present arrangement as there were before. Pedestrians and drivers are more careful and take fewer chances. The schedule rate of the electric cars in Cleveland is nine miles per hour, and in some parts of Boston as high as 12. The value of an electric railway to the public is largely determined by its speed, but the economical aspect of the question is equally important. If we make six miles per hour with horses, and nine with electricity, each car does 50 per cent. more work without increased expense for conductors' and drivers' wages, which is an important item. Another economical feature due to the use of electricity, is the ability to haul one, or even two tow cars without loss of schedule time on special occasions when the traffic is unusually great.

---

[1] Abstract of paper read before the New York Electric Club, Jan. 22, 1891.

Nothing is more astonishing than the capacity of the electric cars to make their schedule time in the face of the heavy storms of a New England winter. It is a common sight to see an electric car running apparently with perfect ease up a heavy grade through snow a foot deep, pushing or pulling other cars loaded to their utmost capacity.

The total number of electric cars now running in this country is probably between 2,500 and 3,000. Of the whole number, I presume not more than 30 or 40 are operated by storage batteries. The fact that the overhead system, though introduced at a later period than either the storage system or the underground distribution system, has so far surpassed them both, goes far to show that as yet it is the only system which has been able to meet the various exacting requirements of our street railway service.

Mr. Pope then spoke in terms of praise of the work of C. J. Van Depoele, Leo Daft and F. J. Sprague, and closed as follows:

The limits of time compel me to content myself with the briefest possible reference to the most important development of electrical transportation which has yet come before the public; the electric underground railway. This undertaking having been placed in the hands of electrical engineers whose competency cannot be questioned, and backed by ample capital has proved in London a phenomenal success. We are now assured that a syndicate of the most prominent capitalists of New York have undertaken to establish a system of transportation upon the same plan, consisting of a network of tunnels at a depth of 100 feet beneath the surface, and connecting all important points not only in the city itself, but in the adjacent sections of Long Island and New Jersey. In such a system it necessarily follows that the train must be run by electricity to the exclusion of any other power.

Every thoughtful person realizes that something must be done at once, not only to relieve the congestion of traffic which already exists in the streets of New York, but to provide for the enormous yearly increase which must be taken into the account. Statistics show that the traffic of the horse cars and elevated lines in New York has increased 46 per cent. within the five years from 1884 to 1889. A careful estimate which has recently been made of the movement of passengers in and about New York during the year 1890, gives the following amazing results:

New York city (surface and elevated roads)..	400,000,000
Brooklyn Bridge..............................	38 000,000
Long Island Ferries..	90,000,000
Staten Island and New Jersey Ferries........	85,000,000
Total..........	603,000,000

If the profit derived from carrying these passengers amounts to only one cent each per trip, it nevertheless figures up to the snug little sum of $6,000,000 per annum, which makes a very comfortable dividend upon a capital of $100,000,000. Such a system would admit of the running of solid trains at very short intervals through the city, and from all points in the suburbs, in every direction, and I venture here and now to predict that within the next 20 years, if not the next 10 years, electrical underground transportation will be brought to such a state of perfection that a passenger entering one of the central stations of New York may be deposited at his home station at any point within a radius of 10 miles in fifteen minutes time, and at a fare of five cents. And this magnificent result is to be the contribution to the convenience and prosperity of the public of the electrical engineer.

Windsor Locks, Conn.—One of the most successful plants of incandescent lighting is the one established last spring at Windsor Locks, Ct. The Electric Light Co. of that town commenced operations at that time with a 500 light dynamo of the Westinghouse alternating current system; since then the capacity of the plant has been increased twice, and to-day the company is able to furnish more than four times the amount of lights of its original capacity. The Westinghouse Electric and Mfg. Company is now engaged with the installation of a 750 light alternating current dynamo.

MR. CORBIN'S PLAN FOR RAPID TRANSIT IN NEW YORK.

A pamphlet has been sent to the Rapid Transit Commissioners, by Mr. Austin Corbin, setting forth his plan for a system of underground electric railways, connecting Battery Park with Brooklyn, Jersey City, and 155th street, and having numerous branches and loops extending east and west throughout the city. The level of the first section, the tunnel under the East River, is fixed at 110 feet beneath the surface. This tunnel, it is announced, will be built in any event, and connections made with the Brooklyn elevated roads, so that even if the whole plan be not accepted, direct and close connection will be obtained between the elevated roads of both cities.

The second section is a continuation of the first, across and beneath Battery Park to a station in Jersey City. The third section provides for a double-track tunnel from the foot of Whitehall street, under Broadway, to the Post Office, with intermediate stations at or near Wall street and Bowling Green. Section 4 is a continuation of this line, from the Post Office, under Broadway to Union Square, where it diverges to the left, continuing under Broadway to and under the Boulevard to One Hundred and Fifty-fifth street; also branching northeasterly from Union Square, to to the line of Third avenue at Eighteenth street, and continuing north under Third avenue to Harlem Bridge; thence northwesterly in close proximity to the Harlem River, until it reaches the line of One Hundred and Fifty-fifth street, forming a complete circuit.

Section 5 is a loop extending from the terminal station at the foot of Whitehall street, northeasterly under Front and Water streets, to the line of Essex street, continuing north beneath Essex street and Avenue A to Tenth street, thence northwest to a connection with the Third avenue line at Twenty-third street. Commencing again at Whitehall street station it continues northwesterly under West street, on a line with the piers and general warehouses to Twelfth street, and thence northerly beneath Tenth avenue to a junction with the Broadway line at Seventy-second street. Section 6 would provide a line to meet the wants developed by the growth of the city in the annexed district. This will be a continuation of the Boulevard line, from One Hundred and Fifty-fifth street on the King's Bridge Road to King's Bridge, and north from Harlem Bridge through Third avenue, having connection with the west line at King's Bridge, forming a circuit around the present Jerome Park.

It is proposed eventually to lay a four-track road on the principal lines of travel, two for high speed and two for way trains The road running parallel with the piers is intended chiefly for the transportation and delivery of freight.

The plan provides arrangements for elevators and underground stations. The elevators at the terminals of the proposed East River tunnel are to have a capacity of 340 passengers per minute. Mr. Corbin states that borings made with a diamond drill at intervals of 500 feet across both rivers, and at numerous points in the city, show a rock formation throughout, with the exception of 2,410 feet in the North River, and possibly a narrow crevasse at Canal street. Over $30,000 has been expended in making these tests.

The cost of a tunnel wide enough for two tracks is estimated at $1,250,000 per mile exclusive of terminals.

The plan is endorsed by gentlemen of great national prominence.

Letters to the Editor.

A PROBLEM IN PHOTOMETRY.

Can any of the readers of The Electrical Engineer give answers to the following problems:

1. In a photometer, suppose the source of light used as a standard to be a large flame with a thin screen in front of it, having a hole in it so as to allow only a part of the flame to shine through it (like in a Methven screen). Query, from where should one begin to measure the distance, from the screen or from the flame?

2. Suppose the screen has considerable thickness, or, to exaggerate, suppose a blackened tube be inserted into the hole in the screen, from where should distance be measured in that case?

3. Suppose, in place of the screen, a parabolic reflector be placed behind the light so as to give a perfectly parallel beam of light, as, for instance, in the Mangin reflectors used in search lights, only supposing the beam to be perfectly parallel; what point should then be taken as the source?

A. T.

Scottdale, Pa.—At a meeting of the stockholders of the Scottdale Electric Light, Heat and Power Company, held Jan. 14th, the following officers were elected for the ensuing year, viz.: Directors, B. F. Overholt, A. S. Loucks, J. W. Ruth, S. C. Stevenson, J. M. McNeil, A. C. Overholt, D. G. Morrow; treasurer, Jacob S. Loucks.

European Correspondence.

LONDON.

Destruction of a Central Station.—Village Lighting.—Death of Prof. Lant Carpenter.—A Committee on Electrical Standards.—Paris and London Telephones.—New Underground Railway.—Electric Railway between Vienna and Buda Pest.

THE news has arrived in England of the total destruction by fire of the Australasian company's central station at Melbourne, causing great inconvenience to the many consumers who were dependent on the station for light.

What may now be considered our propensities for lighting small villages by electricity, is again manifest in a small Welsh village named Abercanaid.

Professor Lant Carpenter committed suicide at his home on Tuesday last. It is said that the deceased gentleman suffered a good deal lately from a mental affection and was under the care of an attendant at the time of his death. A general weak state of health induced him to make a voyage to New Zealand, but when he arrived he became worse, and returned to England at once. Professor Carpenter, who was born in 1841, was the eldest son of the late Dr. W. B. Carpenter, F. R. S. He was educated at the University College School, and took bachelor's degrees in Art and Science at the London University.

The president of the Board of Trade has appointed a committee to consider whether any, and if so, what steps should be taken for the provision of electrical standards. The following is a list of the committee: Lord Rayleigh, F. R. S., and Mr. R. T. Glazebrook, F. R. S., representing the British Association; Dr. J. Hopkinson, F. R. S., and Prof. W. E. Ayrton, F. R. S., representing the Institution of Electrical Engineers; Mr. E. Graves and Mr. W. H. Preece, F. R. S., representing the General Post Office, and representatives of the Board of Trade, including Major Cardew. The first meeting will be held on the 15th of January.

The work in connection with the running of wires for the London and Paris telephone on the English side of the channel has been advanced as far as Ashford, and twenty-five miles of wire will complete the land wires on this side of the channel. The work is done by a corps of men from the Telegraph Department of the Royal Engineers, who number altogether about sixty, and work in gangs at various points on the route. There are four wires, two being return, so that two persons will be able to speak at the same time either at the Paris Bourse or the Royal Exchange, London, where the instruments are to be fixed. The line is expected to be open for use by the end of January, but the cable between the two coasts has yet to be laid. Experiments with the existing telegraph wires showed that the greatest difficulty to be overcome was that of induction. The special wires made of copper are erected crosswise to counteract such effects.

In the last session of Parliament a bill was promoted to acquire powers to construct an underground railway in the district of South Kensington and Underground. This was afterwards withdrawn. A new bill has been prepared in which power is sought to make a subway of a little over a mile and three-quarters in length, in which trains will be run propelled by electricity. A very powerful directorate has been formed, and it is proposed to raise a capital of about £300,000. Of course nothing can be done until the matter has been considered by a Select Committee of the House of Commons.

I mentioned in a previous letter that a scheme was on foot for the construction of an electric railway between Vienna and Buda Pest. I am able to give a few more particulars concerning this project. It is nothing less than the construction of an electric railway traversing a distance of 250 kilometres, for which purpose it is intended to erect six electric generating stations, each controlling an area of 20 kilometres in each direction. It is proposed to maintain the express trains at a speed of 80 or 90 miles an hour, and to charge a fare of three florins for the whole distance. Dr. Julius Kepes has applied for the concession, but the Ministry are by no means as enthusiastic as Dr. Kepes, and they refuse even to enter into the details of the concern until 200,000 florins have been deposited. This, however, is not forthcoming, and probably matters may come to a standstill for the want of funds. It is estimated that fifty million florins are required before the work can be undertaken. It is highly improbable that the money will be subscribed locally as the inhabitants are doubtful of a successful issue.

H. S.

LONDON, Jan. 1, 1891.

COLUMBUS, O.—The Edison Electric Light Co. has elected the following officers: President, Adolph Theobald; vice-president, John Seibert; directors, Charles H. Lindenberg, Adolph Theobald, Emil Kiesewetter, John Seibert, Jacob Bleile, C. T. Pfaff, Joseph F. Martin, F. E. Drake, Louis Seibert.

Home Correspondence.

SAN FRANCISCO.

James Gamble as an Electric Railroader.—President John I. Sabin of the Board of Education.—California Electric Light Stock.—Underground Wires.—Wire Tappers Caught.

I MET James Gamble a few days since. One would expect to find in him a gray bearded patriarch, since his name is inseparably associated with pioneer days of California, but imagine a tall, straight, active, vigorous man of about 50, with beard of the "sable silvered" hue, and you have him as I saw him. He has built, and is operating an electric road from Oakland to Berkeley University, a distance of six miles, and is so enthusiastic that he is now organizing a company to run an electric road from Oakland around San Francisco Bay to San Francisco; taking in Newark, San José, Santa Clara, Redwood City and San Mateo, in all about eighty miles.

As it is proposed to run close to the water's edge all the way, a nicer excursion trip could not be taken and such an enterprise would become very popular. His system is the Edison overhead, and he will not listen to the claims of any other.

We have at last secured a police alarm telegraph and patrol wagon and all are working very satisfactorily. What developments we may expect since John I. Sabin has become president of the Board of Education, is mere conjecture, but as wonders will never cease, an automatic school-marm or a phonographic principal is the least we can expect.

The California Electric Light stock has advanced three dollars per share within the past few days, and is strong in spite of the general financial depression.

The first effort at placing the wires underground through the city was begun some weeks ago by the Telephone, and Western Union Companies, but the work was as suddenly stopped as it unexpectedly began.

J. W. Nagle and William Fallon, two victims of pool rooms, were led not long since into a scheme of reprisal by a discharged operator of the Western Union named Giles. He demonstrated the feasibility of "tapping" the pool room wires and had made a double metallic switch whereby they could receive from the main office, then by aid of an auxiliary battery, resend the dispatches to the pool rooms after detaining the dispatches long enough to give Fallon time to operate in the pool rooms.

Giles, when everything was prepared, informed Mr. Jaynes, of the Western Union, and by his advice, pretended to work in harmony with his confederates. For this he was reinstated in the Western Union and Fallon and Nagle will wear the stripes of convicts for a few years.

SAN FRANCISCO, Jan. 1, 1891.

BOSTON.

The New England Lunch Club.—A Tribute to Col. Ransom.—West End Railway Figures.—New Thomson-Houston Power Generators.

THE New England Lunch Club is the name of a new club formed in Boston for the purpose of providing a first-class restaurant for business men in the vicinity of the Hathaway building and New England building. As these buildings are occupied to a very large extent by electrical enterprises, the Thomson-Houston Company occupying part of both buildings, the members are largely composed of electrical men, so that it is really a down-town electrical club. The initiation fee is ten dollars, and a 50 cent table d'hote is provided, though one can eat a là carte if desired. All interested in electricity, with offices in the vicinity, would do well to become members, as the rooms are pleasantly situated on the top floor of the New England building, and one is sure to meet congenial spirits while lunching.

The January meeting of the Boston Fire Underwriters' Association was held at Young's Hotel, last week, on which occasion a complimentary dinner was given to Col. C. M. Ransom, a gentleman well known to all the electrical fraternity, as lately connected with our contemporary, *Modern Light and Heat*, and now publisher of the *Standard*. The menu provided contained, on the first page, an excellent photogravure portrait of Col. Ransom.

The railroad commissioners gave a hearing this week on the petition of the West End Street Railway Company, for permission to issue $4,500,000 additional stock. A statement was presented showing how the money had been spent derived from the last increase of stock.

The items in this statement were as follows:

Track construction	$ 138,833	97
Difference in value of new tracks over old	418,808	25
Cars and motors	1,308,175	64
Equipment	64,064	45
Electric construction	1,890,380	56
Additions since Sept. 30, 1890	321,141	18
Decrease real estate and horses	136,938	71
Total to Nov. 30, 1890	$3,998,865	34

The statement in addition showed that there is $2,000,000 of stock yet to be issued, but that the increase in property, for which there is a floating debt, is such that if this amount were issued and the floating debt taken up there would be but $128,310.43 unexpended.

The new construction, for which new capital is required, is as follows:

Central power station	$1,200,000 00
East Cambridge power station	650,000 00
Line construction and equipment	500,000 00
Track reconstruction	500,000 00
New car houses	250,000 00
Electric cars	2,400,000 00
Total	$5,500,000 00

The balance sheet of the company, also submitted to the comsioners, is of date of Nov. 30, 1890, and shows:

ASSETS.	
Total fixed property account	$15,805,689 00
Other assets	1,435,571 00
Total	$17,241,261 00

LIABILITIES.	
Capital stock	$9,900,000 00
Coupon bonds	8,250,000 00
Mortgage notes	784,000 00
Floating debt (notes payable, $2,095,748)	2,952,530 00
Total	$16,886,530 00
Surplus	354,730 00

* The hearing was adjourned to February 23d.

The West End Street Railway Company have awarded the contract for the large generators for the new power house to the Thomson-Houston Electric Company. The order at present is for 17 of these generators, but 34 will be required in all. Each generator is to be capable of giving out 360,000 watts, having a maximum voltage of 600 volts, and capable of giving 600 amperes of current. The generators will be built on specifications drawn up by the West End Company, and will be of special design, of the multipolar type, with Gramme armatures. They will measure about 15′ 4″ long by 8′ 6″ wide by about 10 feet high, will run at 400 revolutions per minute, and will not exceed 70,000 pounds in weight. The armature shaft will be 7″ diameter, with bearings 20″ x 5¼″. The commutator will be 30 inches diameter and 15 inches long, having 300 sections. The generators will be compound wound, with six poles and six sets of brushes, and each generator will be provided with complete device for preventing all danger from lightning.

BOSTON, Jan. 23, 1891.

PITTSBURGH.

Chartiers Valley Electric Light and Power Co.—Federal Building Lighting.—Regulating Telephone Rates.—A City Lighting Plant.

THE boroughs of Mansfield and Chartiers, which lie side by side with only the Chartiers Creek intervening, will soon be lighted by electricity. The Chartiers Valley Electric Light and Power Company, a corporation lately organized, has nearly completed its plant. The boilers and dynamos were placed in position a few days ago and the wires are now being strung. About two-thirds of the stock of the company is held by local citizens and the rest by Pittsburghers. Mr. S. A. Duncan, formerly with the Allegheny County Light Company, of Pittsburgh, is now connected with this new company as the general manager.

An electric light plant of 400 one hundred candle-power lamps has just been installed in the Federal Building in this city. The structure is completed, except the inside work of finishing the walls, etc. The darkness, however, prevented any rapid progress of the work and for that reason the incandescent plant had to be resorted to, which is proving a very great success.

A bill was introduced in the State Senate at Harrisburg a few days ago for the regulation of charges for telephone servsce. The bill provides, that not more than $3.00 per month shall be charged for one telephone; that where more than one is in use in an establishment the rates shall not be more than $2.50 for each telephone. It also provides that no payment shall be made for the telephone during any time it is defective or unserviceable. When the Pittsburgh manager of the Central District Telephone Company was asked for his opinion about the proposed bill, he said: "We propose to defend ourselves, and if the legislature passes such a law there will be no telephone system, that is all. We cannot operate telephones for such a price, and as the legislature cannot compel us to do business at a loss we will stop altogether."

Several of the Pittsburgh city officials are very much in favor of the city building its own electric light plant and operating it like the city now operates its water works. The lights for the city streets are now furnished by the East End Electric Light Company and the Allegheny County Light Company at the rate of a hundred dollars per year for each lamp. The officials argue that the city could maintain an electric light plant much cheaper, and that thus a great saving might be accomplished for the city. The matter is to be brought before council in the near future.

PITTSBURGH, Jan. 23, 1891.

Society and Club Notes.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the monthly meeting of the Council held on Jan. 20, the following gentlemen were elected to associate membership:

F. C. Bates, Electrical engineer, with Thomson-Houston Electric Co., Lynn, Mass.

Wm. J. A. Bliss, Assistant in Practical Electricity, Johns Hopkins University, Baltimore, Md.

Edward Caldwell, Assistant Editor, *Electrical World*, 167 *Times* Building, New York City.

Charles F. Chandler, Professor of Chemistry, Columbia College, and Prof. of Chemistry and Physics, College of Physicians and Surgeons, N. Y. C.

Gustave J. Fischer, Engineer for Tramway Construction, Public Works Department, Sydney, N. S. W.

Samuel V. Hoffman, Post-graduate Student, Johns Hopkins University, Baltimore, Md.

Arthur B. Levy, assistant engineer, arc light department, Edison General Electic Co., 235 E. 50th St., N. Y. C.

Thos. R. Taltavall, editor, *Electric Age*, *World* building, New York City.

The following gentleman was elected to a life membership:

A. H. Hardy Trott, electrical expert with Thomson-Houston Electric Co., Lynn, Mass.

EXHIBITORS AT THE PROVIDENCE ELECTRIC LIGHT CONVENTION.

THE following are the names of applicants for space at the Providence electric light meeting received up to January 20th:

New York Insulated Wire Co., New York city, insulated wire and cables; Phœnix Glass Co., New York city, electric glass ware, globes, etc.; Washburn & Moen M'f'g Co., Worcester, Mass., samples of wire; Electric Engineering and Supply Co., Syracuse, N. Y., electric lighting and railway supplies; Swartz & Gannett, Providence, R. I., electric appliances, accumulators, phonographs, etc.; the Eddy Electric Motor Co., Windsor, Conn., motors and dynamos; Jewell Belting Co., Hartford, Conn., belting; American Electrical Works, Providence, R. I., insulated wire; Jenney Electric Motor Co., Indianapolis, Ind., motors and switches; Interior Conduit and Insulation Co., New York city, interior and underground conduit; James W. Queen & Co., Philadelphia, Pa., electrical instruments; Drake, Payson & Whittier, Providence, R. I., electric models, motors and specialties; the Okonite Co., New York city, insulated wire, etc.; the E. S. Greeley & Co., New York city, electrical instruments and supplies; *Electrician* Publishing Co., Chicago, Ill., headquarters *Western Electrician*; Alexander, Barney & Chapin, New York city, general electric supplies; H. T. Paiste, Philadelphia, Pa., switches, cut-outs, etc.; The Bryant Electric Co., Bridgeport, Conn., electric supplies; Bernstein Electric Co., Boston, Mass., series lamps and instruments; T. M. Foote Regulator Co., Boston, Mass., speed regulator; the Holtzer-Cabot Electric Co., Boston, Mass., electric light appliances; John Lynch, Washington, D. C., terra cotta conduits; the C. McIntire Co., Newark, N. J., McIntire connectors, etc.; Eureka Tempered Copper Co., North East, Pa., copper brushes, commutators, etc.; Standard Electric Supply Co., Boston, Mass., voltmeters and ammeters; Narragansett Electric Lighting Co., Providence, N. I., display of incandescent lamps, etc.; the Johns-Pratt Co., Hartford, Conn., vulcabeston insulation; Shultz Belting Co., St. Louis, Mo., belting; the Walker Electric Co., New York city, ammeters, voltmeters, etc.; *Electric Power* Publishing Co., New York city, magazine; THE ELECTRICAL ENGINEER, New York city, journal; *Modern Light and Heat*, Boston, Mass., newspaper; Chas. A. Schieren & Co., New York city, belting; Sperry Electric Light Co., Chicago, Ill., arc lamps, etc.; Thomson-Houston Electric Co., Boston, Mass., recording wattmeters; G. G. Stillman, Boston, Mass., Spencer damper regulator.

Wiring will be undertaken by Drake, Payson & Whittier, Washington and Eddy streets, Providence; G. H. Thurston & Co., 59 South Main street; E. M. Carhart, 18 Custom House street; Swartz & Gannett, Swartz Building, and J. F. Hodge, Jr., 146 Westminster street.

Metal and Supply Market.

REDUCTION IN PRICE OF ALUMINUM.

At the annual meeting of the Cowles Aluminum Co. held at Cleveland on Jan. 22, it was decided to reduce the price to $1.25 a pound. This is a reduction of 50 per cent. It was also agreed to increase the capacity of the works at Lockport. When this is done the company claims it will be able to sell pure aluminum cheaper than copper, taking the weight into consideration, copper being nearly four times as heavy.

Reports of Companies.

NATIONAL ELECTRIC MANUFACTURING COMPANY, EAU CLAIRE, WIS.

This company was organized in November, 1888, with a capital of $50,000, which has been increased to $150,000, and its plant has been doubled in size. The officers are: H. H. Hayden, president; Fitch Gilbert, vice-president; R. E. Rust, secretary; George T. Thompson, treasurer, and George B. Shaw, general manager; the other directors being Peter Truax, A. J. Rust, and J. T. Barber. The plant, equipments and machinery, all of which are new and of improved design, are such as would be expected in a corporation of this kind. One hundred and sixty men and women are employed, and from twelve to twenty men are on the road putting in the company's plants. Machinery for two systems of incandescent electric lighting are manufactured—one the ordinary low-pressure system and the other a long-distance transformer system. The annual output will amount to $1,000,000, and is steadily increasing, the orders for machinery running far ahead of the capacity of the factory. The general management has been in the hands of Mr. George B. Shaw, and much of the progress it has made has been due to his efforts. Mr. Shaw is also secretary of the Daniel Shaw Lumber Company, and has served the city as mayor for two terms, and is now serving as Supreme Chancellor of the world in the order of the Knights of Pythias.

ROCKFORD, ILL., ELECTRIC MANUFACTURING CO.

The stockholders of the Rockford Electric Manufacturing Company met Jan. 13, and elected the following directors: C. C. Jones, A. P. Wells, C. M. Haven, G. F. Penfield, J. W. Calkins, F. E. Calkins, W. F. Woodruff. After the stocholders elected the above-named directors the latter held a meeting and elected C. M. Haven president.

INTERNATIONAL OKONITE CO., LIMITED.

The International Okonite Company (Limited), New York and London, has delared a dividend for the six months ended December 31st, 1890, on the capital stock of the company, at the rate of 8 per cent. on the preference and 10 per cent. on the ordinary shares. As stated in our columns last July, this company is the consolidation of the Okonite Company, of America, with Messrs. Shaw & Connelly, of England, both prominent manufacturers of insulated wires and cables for electrical purposes. This liberal dividend shows an immense business done by the International Okonite Company during the first six months of its existence, and while much of this has undoubtedly been acquired in America, the business done abroad has been considerable.

The manufactory at Newton Heath, Manchester, is rapidly nearing completion, and the necessary machinery is nearly all ready for delivery. When this addition to the existing works comes to be fully developed, a noticeable increase in the English business is looked for. The company handle Okonite insulated wires and cables for aerial, underground and submarine electrical purposes, also Candee and Manson wires. These goods will be vigorously pushed abroad, where their popularity is nearly if not quite as great as in this country.

AFFAIRS OF THE WESTINGHOUSE CO.

Discussing the situation at Pittsburgh on January 22, Mr. George Westinghouse said there were full reasons why the checks of contributors should be returned to them. The sum of $500,000 was not enough to relieve his companies without the aid of stockholders and creditors. He exhibited a new circular to stockholders of the Westinghouse Electric Company, which extended the time of subscribing to the preferred stock from Jan. 26 to Jan. 31. He said that 20,500 shares had already been subscribed for, and assurances given which would bring the total amount to 25,000 shares. Some of these subscriptions are conditioned on at least 40,000 shares being taken, and all subscriptions are now taken subject to that condition. The placing of these 40,000 shares will relieve the company of all financial difficulties and place it in a position to push business.

ELECTION OF THE BRUSH ELECTRIC CO.

The annual meeting of Brush Electric Co.'s stockholders was held in the office at Cleveland on January 19. The following officers were elected: President, S. A. Barton; first vice president, Mr. Bartlett; second vice president, C. A. Coffin; treasurer, J. Potter; assistant treasurer, J. F. Hughes; secretary, S. M. Hamil; assistant secretary, A. B. LeVake; board of directors, S. A. Barton, Mr. Bartlett, J. Potter, Myron T. Herrick, C. A. Coffin, C. L. Pease, W. B. Bolton.

Messrs. Charles F. Brush, George W. Stockly and J. J. Tracy retire from the directory of the company altogether though all three still hold some stock.

The Short Electric Motor Company, in which the Brush Electric Company is a stockholder, also held its annual election of officers, re-electing Mr. Short president and Mr. Potter vice president.

The board of directors of the Brush company met, organized and adjourned to an early day when the policy of the company under the new regime will be formulated.

The same night Mr. Charles F. Brush entertained the party from Boston and some of the Cleveland members of the company, at dinner. Twelve sat down to the table.

STOCKS AND BONDS.

SHERMAN, TEX.—The College Park Electric Belt Line, Sherman, was sold to W. M. Scott on the 6th for $10,000 at trustee's sale under the first mortgage to satisfy two claims aggregating $17,000, held by the College Park Co., who had advanced funds to the Belt Line people. Late the same evening the line was shut down until amicable agreement could be had between the purchaser and the Sprague Co., who hold a second mortgage to secure $21,000 due on the electrical equipment.

LA SALLE, ILL.—A transfer of half the stock in the La Salle electric street railway took place the other day, the Merrifields purchasing the interest of E. S. Enyart, W. H. Stead and W. C. Riale. This stock sold for 120 and the purchase price is said to be in the neighborhood of $50,000. With the transfer of his interest in the road, Mr. Enyart has tendered his resignation as superintendent. It is stated that L. B. Merrifield will be the new manager of the road.

NEWARK, O., is to issue bonds for $49,000 for an electric light plant.

DIVIDENDS.

THE MATHER ELECTRIC Co. has declared a quarterly dividend of 1 per cent., and it is said that the year's business has been very encouraging.

WILMINGTON, DEL.—The Electric Light Co. has declared a semi-annual dividend of 3 per cent.

ELECTIONS.

SANDY HILL, N. Y.—The following have been elected directors of the Sandy Hill Electric Light and Power Company (limited): John H. Derby, Grenville M. Ingalsbe, Marcus C. Allen, J. Edward Howland, Sylvanus H. Kenyon, W. B. Baldwin, Seymour Taylor, Charles T. Beach, and John T. Cunningham. The following officers were elected: President, Marcus C. Allen; vice-president, John H. Derby; secretary, Grenville M. Ingalsbe; treasurer, Charles T. Beach.

KANSAS CITY, MO.—The Kansas City Electric Light Co. has elected the following board of directors: W. B. Grimes, J. S. Chick, J. H. North, F. K. Hoover, W. B. Grimes, Jr., James Scammon, E. R. Weeks, F. N. Chick and O. H. Dean. The Edison Electric Light Co. has elected the following directors: W. B. Grimes, J. S. Chick, J. H. North, F. K. Hoover, W. B. Grimes, Jr., W. P. Hix, E. R. Weeks, F. N. Chick and O. H. Dean.

BINGHAMTON, N. Y.—At the annual meeting of the stockholders of the Thomson-Houston Co., the following directors were elected: John Marsh, Frank Gould, H. E. Bundy, J. E. Shapley, Frank A. Miller and M. L. Keyes.

GRAND RAPIDS, MICH.—The Edison Electric Light Co. has elected the following officers and directors: President, Daniel McCoy; vice-president, C. P. Gilbert, Detroit; secretary, Thomas Bechtel; treasurer, Daniel McCoy. Directors, Messrs. C. M. Ayre, J. M. Barnett, John A. Covode, W. R. Shelby, Daniel McCoy, C. H. Gilbert, of Detroit, E. W. Voigt, Detroit, J. R. Markle, Detroit, and J. H. Beggs, Chicago. The report of the company shows a very satisfactory standing. It now has in the city 7,000 incandescent lights, 149 arc lights, and 75 h. p. motors, and with the contemplated addition to the company's plant the facilities will be greatly increased.

MANCHESTER, N. H.—A vote of the Manchester Electric Light Co. taken for directors shows the following result: Frank Dowst, J. W. Hildreth, H. E. Parker, J. B. Varick, William L. Elkins, Jr., J. C. Moore, J. A. Weston, A. Elliott and George F. Lincoln.

LEBANON, PA.—The new officers for this year of the Lebanon and Annville Electric Railway Co. are: President, A. Reinoehl; directors, L. Nutting, S. Brightbill, L. E. Weimer, J. M. Shenk, H. H. Kreider, E. H. Brooks, H. H. Light, W. L. Kreider and R. Mitchell; treasurer, J. H. Hoffer, and secretary, R. Mitchell.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JAN. 20, 1891.

Accumulators:—

Electrode for Secondary Batteries, F. Bain, 444,969. Filed Oct. 17, 1890.

The electrode comprises an envelope of perforated metal containing active material and a porous conducting material, such as carbon.

Clocks:—

Independent Electric Clock, E. Lefebvre, 445,023. Filed Oct. 6, 1890.

Relates to the class of clocks in which electrical energy replaces the usual weight or main-spring: combines electrical energy and the force of gravity.

Clock-Winding Mechanism, W. N. Packer and W. W. Bradley, 445,073. Filed May 5, 1890.

Electro-magnetic self-winding apparatus for clocks driven by weights.

Conductors, Conduits and Insulators:—

Insulator, C. Elkins, 444,879. Filed Apr. 22, 1890.

An insulator and supporting arm adapted to allow a free movement either of the wire through the insulator or the insulator on the wire. A rectangular frame, in two parts, has an insulating anti-friction roller on each of its four sides, and is suspended by a jointed arm.

Insulator, W. Vogler, 445,008. Filed May 23, 1890.

Especially adapted for use upon overhead conductors of electric railways. Consists of an inner body of high insulating capacity and an outer body of high refractory nature to protect the inner body.

Machine for Covering Wire, G. Lispenard, 445,120. Filed Oct. 31, 1889.

Claim 1 follows:

The combination, substantially as hereinbefore set forth, of a main frame, a revolving bobbin-holder having a vertical axis and constructed to support a bobbin or coil of covering material concentrically therewith, devices for feeding a wire or core centrally through the bobbin-holder and through the bobbin, a holder for reserve bobbins above the bobbin-holder, and means for rotating the bobbin-holder and actuating the wire-feeding devices.

Dynamos and Motors:—

Regulating Apparatus for Electric Motors, M. J. Wightman, 444,900. Filed Sept. 19, 1890.

Relates to the apparatus shown in the same inventor's patent No. 435,958, Sept. 9, 1890. The present invention consists in a switch by which a single operating lever is used to make all the connections requisite for coupling two or more motors, driving the same machinery, in various ways, as in series or multiple arc.

Alternating-Current Motor, C. O. C. Billberg and P. A. N. Winand, 444,934. Filed June 10, 1890.

Claim 1 follows:

An alternating-current motor having an armature in the form of a laminated Faraday disc or cylinder and electro-magnets to act thereon, having one or more primary and one or more secondary windings, the armature being connected in the secondary circuit.

Alternating-Current Dynamo, H. Lemp and L. M. Schmidt, 444,939. Filed Sept. 8, 1890.

Designed for use where large or sudden changes of load occur; especially applicable to electric welding. The invention consists in the combination with the armature of a work circuit fed from the armature, a field magnet circuit having a commutator for locally rectifying the alternating currents, but in series with the work, and a branch around the work through which the alternating currents pass in the initial excitation of the machine to the commutator for the field magnet circuit.

Electric-Motor Reciprocating Engine, C. J. Van Depoele, 445,102. Filed April 18, 1890.

Claim 2 follows:

A reciprocating engine comprising an electric motor having a stationary part or field-magnet, a rotating part or armature revoluble therein, a tool-stock adapted to be reciprocated through said rotating part or armature, the latter being sleeved thereupon, a motor-spring acting upon and imparting the power-stroke to the tool-stock, and means carried by said rotating part or armature for alternately compressing and releasing the motor-spring.

Ignition:—

Automatic Electric Igniting Device, T. W. Lane, 444,896. Filed June 13, 1889.

For turning on gas and automatically lighting it. The object of the improvement is to so construct and adjust the pawl-carrying bar with the armature, that the bar may be capable of more extended movement than the armature, thus effecting a sufficient movement of the gas-cock without an inconveniently large excursion of the armature.

Lamps and Appurtenances:—

Combined Electric Motor and Lamp-Socket, R. H. Beach, 444,807. Filed Aug. 21. 1890.

A small fan motor provided with an extension adapting it to be inserted in a lamp-socket in place of the lamp when desired.

Electric-Arc Lamp, E. Thomson, 444,925. Filed Nov. 22, 1884.

Instead of relying for regulation upon the differential action of a direct and a shunt electro-magnet, as in usual practice, the organization is such that the direct-circuit magnet and the derived-circuit magnet are in a measure independent. The derived-circuit magnet is opposed by a spring, and the force in play in adjusting the carbons is sometimes that of the direct-circuit magnet alone, and at other times it is the surplus of force which the derived-circuit magnet exerts over the restraining force of its opposing spring.

Incandescent Electric Lamp, E. Thomson, 444,920. Filed Aug. 4, 1890.

Applicable to lamps designed for use in series with one another or with arc lamps on circuits carrying high potential currents. Relates to the provision of means for automatically completing the circuit in case of the rupture of the filament. Consists broadly in the application to lamps having an automatic cut-out device of a supplemental cut-out adapted to be operated by the disruptive action of the current on the failure of the arc to form on sudden interruption of the current in the lamp by breakage of the filament.

Electric-Arc Lamp, W. H. Elkins, 444,977. Filed July 26, 1890.

A combination of two distinct lamps with a spring switch composed of two blocks and a spring actuated movable portion controlled by a magnet which is part of a shunt circuit; like terminals of the lamps are connected with the switch block and the other terminals with the main circuit; the shunt circuit is broken when the first lamp is cut out.

Multiplex-Arc Lamp, W. H. Elkins, 445,136. Filed Oct. 25, 1890.

Amplification of No. 444,977 above.

Measurement:

System of Distributing and Metering Electric Energy, E. Thomson, 444,930. Filed Sept. 22, 1890.

Relates to distribution for series or constant current lines. And the object is to provide for measuring the amount of energy used at different points on such lines. Each lamp or set of lamps, or other translating devices, is placed in a loop of the main circuit, and across each loop a measuring device is connected in such a manner as to obtain a registry, not of the current flowing on the line, but of the difference of potential at the ends of the loop. The voltage of the lamps being known, account may thus be taken of the number of lamps used in each loop or of the aggregate period of use, by making virtually a registry of the volt hours.

Electric Meter, E. Thomson, 444,931. Filed Sept. 22, 1890.

For measuring the consumption of energy in translating devices operated upon constant-current or series circuits. Consists in combining with the translating devices an electric motor of any suitable kind having the usual field magnet and armature, one element of which motor is traversed by a current varying according to the differences of potential at the terminals of the loop containing the translating devices, while the other element has an excitation substantially constant in amount, and a registering device for registering the movements of the movable element of the motor.

Electric Indicator, C. Wirt, 444,966. Filed Jan. 6, 1890.

An indicator or meter applicable either as a voltmeter or as an ammeter by varying the character of the conductor or coil.

Claim 1 follows:

The combination of a conductor, an armature suspended in proximity thereto, and an indicator operated by such armature, said armature free to move only so that each point of its effective surface traverses a path equidistant from that of the current at the effective portion of the conductor.

Metal Working:

Portable Electric Welding Apparatus. E. E. Ries, 444,855. Filed Aug. 2, 1890.

A welding apparatus or outfit including a generator which can be transported from place to place; especially adapted for use along a line on which at predetermined intervals electric welding is required for the production of continuous structures, as rails or conductors for electric railways, or pipe lines.

Electric Blank-Heater for Forging-Machines, G. D. Burton, and E. E. Angell, 444,914. Filed Oct. 7, 1890.

The electrodes and their co-operative parts are adjustable to suit blanks of various lengths for forgings of different sizes; the electrodes are adapted automatically to grasp and release the blanks, and are under the control of the operator for determining the heating periods.

Claim follows:

In an electric blank-heater, the combination of two electrodes adapted for holding a blank to be heated, and vertical and horizontal oscillators for imparting vertical and horizontal oscillation to said electrodes.

Method of Electric Welding, E. Thomson, 444,926. Filed May 15, 1888.

Applicable particularly to the operations of electric welding set out in the same inventor's patents Nos. 347,140 and 347,141. Designed to facilitate the operations and to keep control of the temperature of the objects operated upon. Consists broadly in first applying a current of great heating effect, accumulating heat in the object under such current until the required temperature is nearly attained, and then diminishing the current, but not so much as to prevent the rise of temperature to the proper point.

Method of Electric Welding, E. Thomson, 444,927. Filed May 15, 1888.

Relates to the processes of metal working set forth in the same inventor's patents Nos. 347,140, 347,141 and 347,142 and in British patent No. 10, 241 of 1886. Similar in part to No. 444,926, above; but adds provision for gradually diminishing the heating current from the start.

Method of Electric Welding, E. Thomson, 444,928. Filed June 14, 1890.

Relates particularly to the process of joining strips, sheets, plates or bars of metal where a weld of considerable length is required, as joining plates at their edges, joining strips or ribs to plates for strengthening them, forming longitudinal joints in the manufacture of metal pipes, &c. Consists essentially in feeding the work in the longitudinal direction of the joint through suitable pressure devices during the passage of the heating current.

Method of Electric Welding, E. Thomson, 444,946. Filed May 15, 1888.

Consist, essentially, in maintaining at the points at which the current enters and leaves the work, an approximately constant difference of potential, so as to effect a gradual heating af the work automatically through the gradual increase of resistance of the work due to its increasing temperature.

Miscellaneous:—

Electric Gate, H. Gillette, 444,825. Filed Oct. 3, 1890.

The gate posts are provided with a guard-bar mechanically connected to two electric motors; a generator, circuit closers and automatic circuit breakers are provided.

Electrical Exercising Machine, J. B. Gardiner, 444,881. Filed June 2, 1890.

A combination of mechanical and magneto-electric apparatus whereby electric currents are generated through the energy expended by the operator and transmitted through his person during his exercise.

Combined Cut-Out and Lightning-Arrester, A. T. Aldrich, 444,892. Filed June 20, 1890.

Particularly applicable for telephone lines. Consists of details in the construction and mode of supporting the fuse-wire holders and in combining with the holders and fuse-wires suitable connections with one or more ground wires.

Electric Switch, B. B. Keyes, 445,146. Filed Aug. 16, 1890.

A circuit breaker and closer of the quick acting or "snap" type.

Railways and Appliances:—

Railway-Signal, N. B. Creigier, 444,819. Filed Oct. 25, 1887.

The principal object is a train-signalling system in which a signal sent from any car of a train to the engine or from the engine will be repeated automatically in every car of the train. It is a closed circuit system.

Claim 1 follows:

In a signal system for railway trains, the combination of a closed circuit for the electrical current and mechanical generators, signalling devices, and switches in and operating on said closed circuit.

Snow-Sweeper, I. F. Baker and R. Booth, 444,871. Filed Jan. 29, 1890.

Relates to rotary sweepers, and is especially applicable to snow-sweepers for street railways in which the cars are propelled by self-carried electric motors supplied by a current from an outside source through a line of conductors.

Trolley for Electric Railways, H. H. Blades, 444,893. Filed Aug. 11, 1890.

Claim 1 follows:

In an overhead trolley for electric railways, the combination, with the trolley-rod pivoted at its base to the supporting-plate, of two coil-springs having their lower ends rigidly engaged to the said supporting-plate and their upper ends engaged to the rod above its pivoted end.

Mounting for Electric-Car Motors, E. W. Rice, Jr., 444,922. Filed Aug. 15, 1889.

The frame consists of side pieces and a uniting cross-piece; the motor has the field-magnet supported at its yoke and on the side-pieces of the frame and at its pole ends by extensions from the poles resting upon the cross-piece of the frame.

Electric Motor Truck, R. P. Faries, 445,051. Filed Sept. 23, 1890.

Friction wheels or rolls are yieldingly held in contact with the truck wheels and flexibly connected with and arranged to be driven by the armature shaft.

Trolley-Wire Clamp or Support, W. Vogler, 445,103. Filed April 8, 1890.

Consists of two members grooved at their inner sides to enclose the trolley-wire over more than half of its circumference; the members are clamped together and are provided with a locking device to retain the ends of the conducting wire.

Electric Signal for Railroads, E. C. Wiley, 445,106. Filed May 15, 1890.

Consists, generally, of two line wires parallel to the track having branches leading to points adjacent to one of the rails, together with devices actuated by the car wheel and circuit-closing brush on the locomotive tender; the signalling devices thus operated being intended to sound an alarm upon locomotives approaching each other on the same track.

Trolley-Wire Support for Electric Railways, J. S. Hughes, 445,142. Filed April 19, 1890.

Consists essentially in an arch of tubular cross section, resting upon posts at the sides of the streets, in place of the ordinary span wire.

Electric-Railway Car, R. M. Hunter, 445,144. Filed Oct. 4, 1886.

The electric motor, carried by the car body, is located below the floor and independent of the truck; the frame for the gearing and motor shaft is sleeved on the axle independent of the car body.

College Notes.

COOPER UNION, N. Y. CITY.

A free class in electrical measurements for advanced students has been established at the Cooper Union. The lectures are given by Prof. Robert Spice every Friday evening at half-past eight o'clock.

HARVARD.

Professor Hall and the men in Physics paid a visit to the stations of the Boston and of the Edison Companies, a short time ago, and spent a very pleasant evening in inspecting the machinery. It is an agreeable feature of electric light stations that no matter how late you come, the station is still open. Whether you call at eight o'clock or twelve, you receive the same warm greeting.

Two very interesting lectures were given last month before the members of the Electric Club. The first was upon Self-Induction, by Mr. Sabin, of the Jefferson Laboratory; the second upon Magnetism, by Dr. Wilson, also of the Jefferson Laboratory, who has done much valuable work in this subject.

There are at present seven Harvard men with the Thomson-Houston Company. They are graduates of the college, or of the Lawrence Scientific School. Their names are L. K. Perot, L.S.S.; E. A. Bailey, L.S.S.; E. H. Lewis, L.S.S.; J. C. Barr, '90; P. M. Reynolds, '90; R. G. Fessenden, '90; and F. H. Kennard, '88. Of these Mr. Kennard is at the Boston office, Messrs. Barr, Fessenden and Reynolds are out on the road from the factory, and the rest are at Lynn. Mr. Perot is at work on the characteristic curves of the motor-type dynamo, Mr. Bailey is testing the magnetic qualities of various kinds of iron, and Mr. Lewis is engaged upon some ballistic work, of which Mr. Perot is soon to take charge.

A series of lectures by Mr. B. I. Gilman, on the "Psychology of Music," opened last week in Sever Hall. The earlier lecture in this course will deal with pitch, timbre and other properties of sound. Many of the Physics men were present, but whether to refresh their knowledge of acoustics or to smile at the fair scientiste from the "Annex" I can't say. The lecturer sounded notes from 16 vibrations a second up to 25,000. The audience failed to hear anything below 32 or above 22,000.

I understand that the lectures in Physics for freshmen are to be given in the evening instead of the morning, this year. They will begin on Wednesdays.

The Electric Club has adjourned for the mid-year examinations. Preparations are being made for the course of public lectures. Probably six or eight will be given.

At the last meeting, Mr. Smith, the secretary, resigned, and Mr. G. S. Curtis, '92, was elected to his place. Mr. Hoppin, '93, was elected to fill Mr. Curtis' place on the Executive Committee.

G. T. P.

Legal Notes.

WESTERN UNION'S TAXES IN MASSACHUSETTS.

H. C. Bliss, assistant attorney general for Massachusetts, at Washington, began, on Jan. 19, the argument for the Commonwealth in the case against the Western Union Telegraph Company for taxes. The defence of the Western Union Company appears to be that it is operating under a national charter, the Federal Act of 1866, which exempts it from local taxation. Mr. Bliss presented in the case a letter of Norvin Green, president of the Western Union, to Postmaster-General Wanamaker in the postal telegraph controversy, in which Mr. Green did not seem to attach much importance to the Federal laws of 1866. The hearing will be concluded to-morrow.

DAMAGES FOR AN EXPLOSION.—A QUEER VERDICT.

In Common Pleas Court, No. 1, Philadelphia, President Judge Allison presiding, a verdict has been rendered in favor of Elizabeth McCardle against the Penn Electric Light Company, of New Jersey. The claim was based on the allegation that the husband of Mrs. McCardle was so badly burned by an explosion of gasoline at 908 Sansom street, on November 17, 1887, that he died a short time thereafter; that he was in the employ of the company, and that the explosion was caused by the negligent manner of filling and lighting a gasoline lamp in the building by another, where Mr. McCardle was in the pursuit of his employment. The defence set up that he was not in the employ of the company, and that even if he were, she could not recover because the accident was due to the negligence of a fellow-workman. The jury gave Mrs. McCardle $4,300 damages.

Appointments, Etc.

MR. H. F. WATTS has resigned as superintendent of the Meriden, Conn., electric railway.

MR. T. H. CHRISTIE has been appointed assistant superintendent of the Rochester, N. Y., Electric Railway.

MR. C. L. PEASE, of the Westinghouse Electric Co., has become associated with the management of the Brush Electric Co., of Cleveland.

MR. F. A. SCHEFFLER, of the Westinghouse Electric Co., has joined the forces of the Brush Electric Co. in Cleveland.

MR. F. G. SCHLOSSER, a Cornell University man, was appointed lately superintendent of the electrical department of the Laclede Gas Co. Mr. Schlosser has been connected with the department as superintendent of construction for over a year past.

MR. MORTON EDEN, lately of the Essex Electric Railway Co., Salem, Mass., and formerly with the Brush Corporation, of England, has been called to Cleveland to take a position in the construction department of the Brush Electric Co.

MR. A. G. REYNOLDS, of Toledo, O., has succeeded Mr. J. A. Duggan, as superintendent of the Quincy & Boston Street Railway Co.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of January 24, 1891, from New York, Boston and Washington; Pittsburgh, January 23.

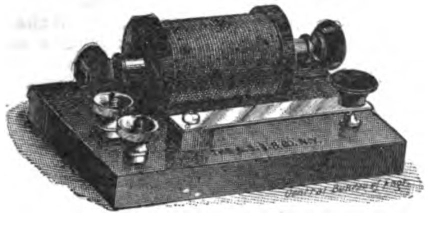
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"If you would move the electrical trade, try the motor of advertising."

THE FREY MAGNETO ELECTRIC BRAKE.

THIS is a convenient little contrivance for checking the swing of the needle or system of a fibre suspension galvanometer, by sending a slight induced current through the coils, the effect of which is to tend to swing the system in a direction opposite to that in which it is moving. The current being slight and capable of being nicely regulated, the deflection can be readily brought to zero. The instrument consists of a coil, the terminals of which are connected with the galvanometer through a contact key. A small bar magnet is pushed or pulled through the coil.



THE FREY MAGNETO ELECTRIC BRAKE.

This apparatus is the invention of Mr. Charles P. Frey, and is being placed on the market by The E. S. Greeley & Company, of New York.

F. & M. DEP'T, HARRISBURG CAR M'F'G CO.

The F. & M. Department of the Harrisburg Car M'f'g Company, as we stated some weeks ago, will soon be reorganized as a separate company. In the meantime they are full of work and could do even more than they are doing at present, were they in a position to go ahead and push harder, as they will be at the consummation of their reorganization. Of course it takes some time to hear from all their creditors and stockholders as to the organization of the new company, but as the F. & M. department has always been a handsomely paying enterprise apart from the Harrisburg Car M'f'g Company, itself, it seems too bad that its works should have been crippled and that it should be carried down with the car manufacturing company, through no fault of its own. However, the cloud is only temporary and will soon blow over, if, indeed, it has not already vanished in thin air.

ELECTRIC STREET CAR GEARING.

The following letter has been received by the New Process Raw Hide Company, of Syracuse, N. Y., and which is explanatory of itself :

SCRANTON, PA., Jan. 9th, 1891.

THE NEW PROCESS RAW HIDE CO., Syracuse, N. Y.

Gentlemen :—In reply to your favor of the 6th inst., would say that I have experimented with most everything in the way of motor pinions and find nothing that works so satisfactorily as pinions of your manufacture.

I am so thoroughly satisfied that the raw hide pinions of your manufacture are the best kind of pinions on the market, that I am equipping all our cars with them and will not look at any other kind.

The first I tried, those without being rivetted, ran 15,490 miles, and were to all appearances good for 1,000 miles more.

Yours very truly,

[Signed] J. H. VANDER VEER,
Gen. Mgr. Scranton Street Railways.

EUREKA TEMPERED COPPER IN ELECTRIC RAILWAY PLANTS.

The following letter is very interesting as throwing a little light on some of the questions of electric street railway work :—

KEY CITY ELECTRIC STREET RAILWAY CO.,
Dubuque, Ia., Dec. 27, 1890.

EUREKA TEMPERED COPPER CO., North East, Pa.

Gentlemen :—I send you by express to-day sample ratchet brake casting for pattern. Supply cog for the one broken out in the pattern.

Please make and ship by express as soon as possible one dozen tempered copper ratchet castings. I will send one of them to the manufacturers of our cars and explain that we broke on an average of one a day of cast iron ratchets and recommend the use of tempered copper for ratchets.

The tempered copper liners made for the John T. Noye Mfg. Co., Buffalo, N. Y., for their engine, which was installed here some months ago, were put in by us a few days ago and are giving perfect satisfaction. Up to this time we were unable to find any liners that would stand the severe service. I will report the matter to the Noye Co. and recommend that copper liners be used on the new engine which they are making for this new company. Possibly it may lead to their being adopted by them generally.

Yours truly, JOS. ANGELL, Sec'y.

ANSONIA BRASS & COPPER CO.

The Ansonia Brass & Copper Co. have issued a very tasteful New Year souvenir. It is bound in celluloid with leather back. The contents are a series of views of their huge brass rolling mills, copper rolling mills, lamp, chandelier and wire insulating factories, wire mills and the Ansonia clock factory in Brooklyn. The pictures are most impressive, and give one an idea of the enormous extent to which the various industries have grown up and ramified during the last few years. On the back cover is an engraving of the handsome headquarters occupied at 19–21 Cliff street, this city.

THE BERLIN IRON BRIDGE CO.

The business of the Berlin Iron Bridge Co., of East Berlin, Conn., has increased so rapidly in the last few years that the stockholders deemed it advisable at the annual meeting on Monday, the 19th. to increase the capital stock from $125,000.00 to $300,000.00. The entire increase has already been subscribed for by the present stockholders.

The additional capital will be used to improve their plant at East Berlin, and the company will immediately put up a new building 80 ft. wide by 600 ft. long and expect to have it equipped with machinery and in running order by the 1st day of July.

During the past few years this company have been compelled to run their works day and night during the greater portion of the time, but with their improved facilities they will be able to do 25 per cent. more work than they have been doing and not run their plant over ten hours per day.

They have shipped during the past year 8,000 tons of iron work consisting of iron bridges, iron buildings, and iron roofs. Their sales amounted to nearly $1,000,000.00 and their work was put up in nearly every state in the Union. The company now have regular established agencies in San Antonio, Texas, Binghamton, N. Y., Buffalo, N. Y., Pittsburgh, Penn., Raleigh, N. C., Dayton Ohio, Enterprise, Miss., and Omaha, Neb.

The prosperity of the company is attested by the greatly increasing demand for their work from all parts of the country, and by the fact that the large increase in the capital stock was fully subscribed for by the present stockholders.

ALUMINUM BRASS & BRONZE CO.

T. L. Fowler, manager New York office, Aluminum Brass & Bronze Co., 53 Chambers street, has been appointed general manager of the above company and transferred with headquarters at Bridgeport. Mr. Frank G. Stone, general sales agent, assumes charge of the New York office in place of Mr. Fowler and will continue to convince all comers that the silicon bronze wire is the best for purpose to which it is adapted.

TUCKER & HALL.

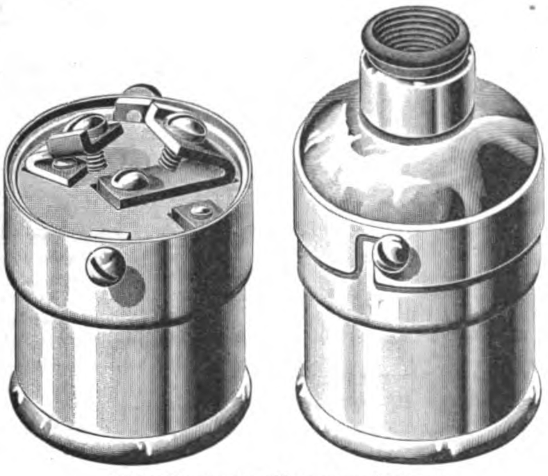
Tucker & Hall, of No. 8 Pulitzer Building, is the name of a new firm of electrical contractors. The men constituting this firm are old practical men, having been connected with electrical construction for some 12 years back. They start in with the very best wishes of a large number of people who happen to know them, and have under way and finished the following contracts : Metropolitan Life Insurance Co., New York ; Central Trust Co., New York ; Union Trust Co., New York ; Pulitzer Building, New *World* Building ; Central R. R. of N. J. Building ; Morgan S. S. Line, 2 piers ; Chas. Horn's Silk Mills, New York ; St. John's College, Fordham, N. Y. ; Smith, Gray & Co., Brooklyn, N. Y. ; McLoughlin Bros., Brooklyn, N. Y.

FILLEY, PARKER & FILLEY, of 296–300 Oakland street, Greenpoint, Brooklyn, E. D., are licensees for Connecticut, New York and New Jersey of the Harvey-Filley Aluminum Plating Co's. process of aluminum and bronze plating. This process gives a most beautiful and lasting finish and will no doubt prove of considerable interest and advantage to the electrical people, such as the plating of instrument cases and work of like nature.

THE "ELECTRIX" KEYLESS SOCKET.

We illustrate in this issue a new keyless socket, the "Electrix," which is just being brought out by the Star Electrix Co., of Philadelphia. This socket is made to fit any lamp and contains nothing in its make up but porcelain and brass. It is easily wired and considered very neat in appearance.

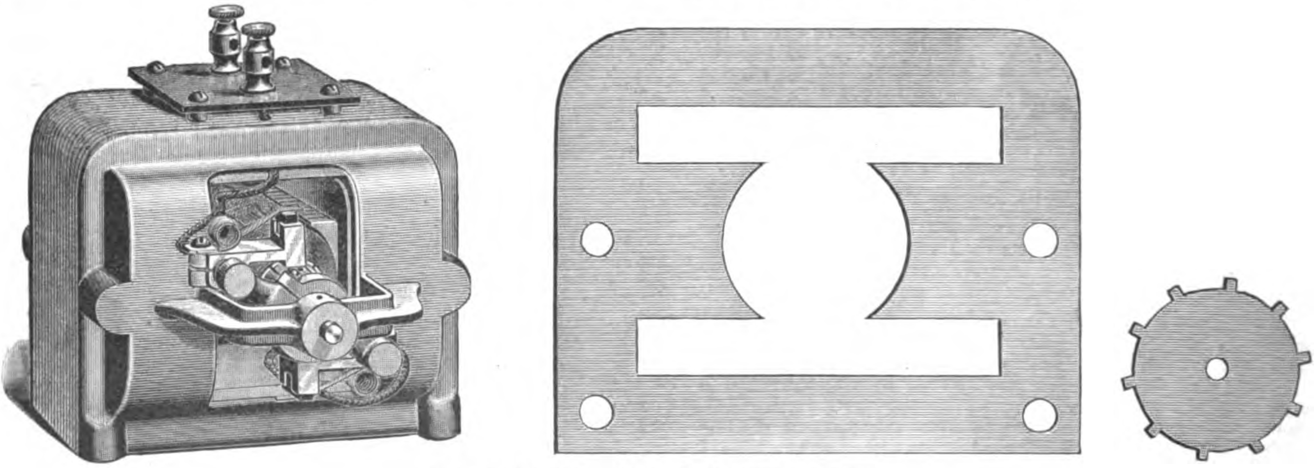
This enterprising firm continue to add new things every few weeks and already have quite a complete line of electric lighting supplies such as 5 amp. and 10 amp. S. P. switches, 25 amp. D. P. switches, key and keyless sockets, insulating joints, gas attachments, ceiling cut-outs and branch and main cut-outs, etc.



THE ELECTRIX KEYLESS SOCKET.

SMALL HIGH CLASS MOTORS.

It has been remarked that it requires greater care and a more profound knowledge of the science of electrical engineering to design and construct a highly efficient motor or dynamo, of, say, one-eighth horse-power than is necessary to design and construct one of ten h. p. or larger. But to meet a demand for an efficient small motor, Mr. Forée Bain, of the Bain Electric Manufacturing Co., 47 and 49 South Jefferson street, Chicago, has designed the machine shown in the engraving, Fig. 1. The field magnets and armature cores of the machine, as shown in Figs. 2 and 3, are stamped of the best soft sheet iron. The sheets of the field magnets, in which there are no joints, are then varnished and held together by a stud in each side, this stud also passing through a cast iron guard on either end. This guard answers as a means for making the motor "iron clad," and it also carries the two bearings. The shaft is made of best Stubbs steel ground true on centres. The armature has a Siemens core with Pacinotti projections, and its winding is Mr. Bain's modification of the Frölich method. The commutator is large and solidly made, and the brushes are made of a patent material resembling carbon. The advantages claimed for this little motor are numerous.



FIGS. 1, 2 AND 3.—NEW BAIN SMALL MOTOR.

As the field coils are placed as near to the armature as possible, all the lines of force of the field coils are concentrated in the core, and there are no radiating magnetic lines of fore, and the machine is "iron clad."

The best mechanical construction has been adopted; the bearings do not require oil or grease, or lubricant of any kind, and as the machine is self-contained, no nuts, bolts or screws can become loosened.

Machines of this type are carried in stock from one-twelfth horse-power to one horse-power, and they are wound for battery work from 2 volts to 25 volts, and also wound for 110 volt current and constant current of from 6½ and 10 amperes.

POPULARITY OF CROCKER-WHEELER MOTORS.

The Crocker-Wheeler Motor Co. are having large orders for their perfected motors. Among the installations recently made are the following: The Union Club, Hotel Normandie, New York Whist Club, The National Bank, Dr. Fuller, Thirteenth street and Fifth avenue; Photogravure Co.; Star Theatre; Metropolitan Tel. & Tel. Co.; Worthington Pump Co.; Malony's saloon, 1 Park Place; Nilson's, Equitable Building; Rogers & Co.; Ellsworth & Co.; Johnstone, 22 John street; Sutton, 466 Third avenue; Glattstein, 450 Broome street; Bergmann, 110 West Twenty-fourth street; Lang, 157 East Forty-second street; Gilbert, Heiland & Beitler. They are also finding extensive sale for their new reversible motors with fire proof regulators, and have sent several of these among a large shipment recently to their London house, The General Electric Co.

THE STANLEY & HALL CATALOGUE.

One of the handsomest trade catalogues of the season is that just issued by the pushing and painstaking firm of Stanley & Hall, the manufacturers of electrical house furnishings, 32 and 34 Frankfort street, this city. Unless a maker of such apparatus is of progressive tendencies his printed matter will soon lose its interest, and his catalogue becomes a mere list of museum antiquities with which the public have but little concern. The example of catalogue-making before us is in its way as thorough a piece of enterprise and originality as the Pulitzer building that stands so near the Stanley-Hall factory.

The book is of 70 quarto pages, handsomely bound in blue, with the lettering on it in a shade of deeper blue, together with a large picture of their "S. H." bell, in a rich red. The typography is excellent, no small type being used at all, while the figures for prices are unusually large and clear—though the largeness does but emphasize the actual smallness of the quotations appended to the various articles. All the apparatus shown is new and fresh and in active demand in the market, and all necessary details are given in regard to it. There is moreover at the end a complete and well arranged index. The firm makes an admirable showing of its products and specialties, and is evidently destined even on its present lines to turn out a fatter volume every year.

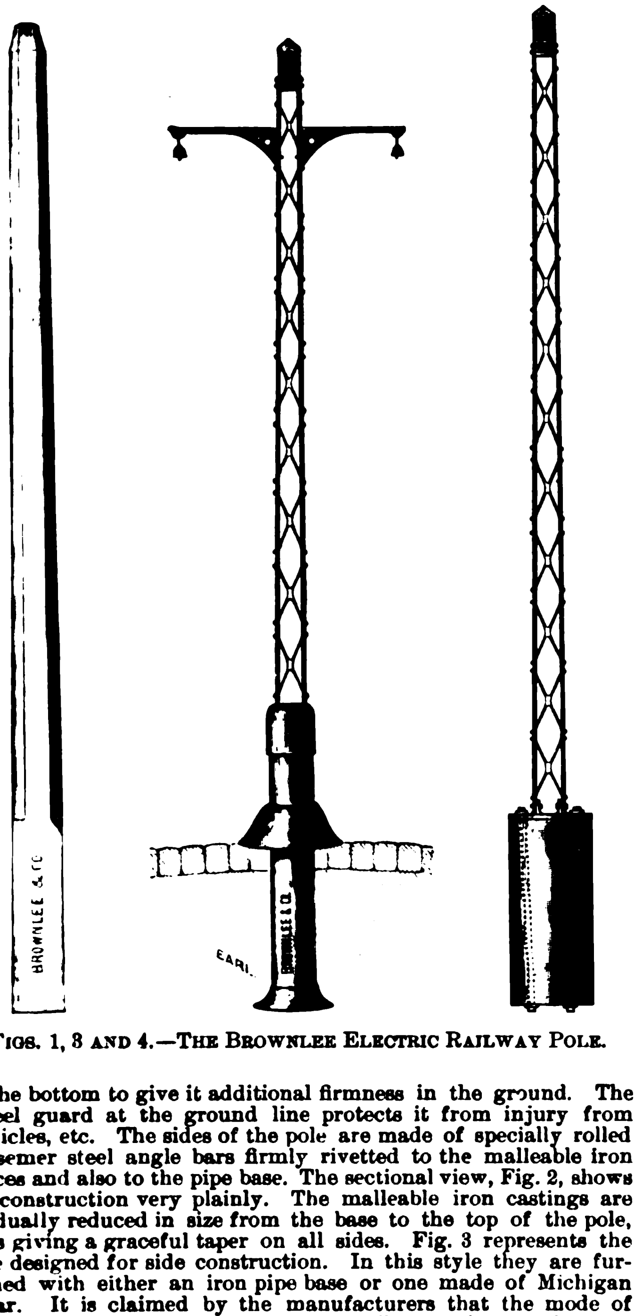
THE CUTTER STREET HOOD.

In many places outdoor incandescent lights are preferable to arc lamps, and with a good reflector and a good protection to the socket they are quite practicable. This accounts for the large sale of Cutter's street hood, which combines a protecting covering for the socket with an enameled reflector. This reflector is shaped so as to distribute the light evenly over a wide area, and is hinged so as to admit of ready access to the socket. This hinge in turn was designed to allow the hood to be shipped in pieces and to be put together without the use of solder or even of a screwdriver. Such points about a street hood seem to count, and Mr. George Cutter is busy making them at his new shop.

BROWNLEE'S ELECTRIC RAILWAY POLES.

Electric street railway work has called forth a demand for light, strong and graceful iron pole to remove as far as possible the objections which are frequently raised against the placing of poles in streets. To meet these requirements Messrs. Brownlee & Co., of Detroit, Mich., have recently brought out the novel types iron pole illustrated in the accompanying engravings.

The pole designed for centre construction is shown in Fig. 1. As will be seen, the base of the pole is made of pipe with a flange at the bottom to give it additional firmness in the ground. The wheel guard at the ground line protects it from injury from vehicles, etc. The sides of the pole are made of specially rolled Bessemer steel angle bars firmly rivetted to the malleable iron braces and also to the pipe base. The sectional view, Fig. 2, shows the construction very plainly. The malleable iron castings are gradually reduced in size from the base to the top of the pole, thus giving a graceful taper on all sides. Fig. 3 represents the pole designed for side construction. In this style they are furnished with either an iron pipe base or one made of Michigan cedar. It is claimed by the manufacturers that the mode of bracing these poles gives the greatest stiffness and strength.



FIGS. 1, 3 AND 4.—THE BROWNLEE ELECTRIC RAILWAY POLE.

Fig. 4 represents an octagonal wood pole which was introduced by Messrs. Brownlee & Co. a little over a year ago, and is now well and favorably known. During the last season they were unable to fill all orders offered, but have now increased their facilities and are now prepared to supply the steadily increasing demand.

ENGLISH, MORSE & CO.

The Kansas City firm of English, Morse & Co. have shipped the past week to Garnett, Kan., a 60 h. p. Ide engine. It will be used in a combined electric light and water works station which the city have contracted for. They have also shipped an additional 50 h. p. steel boiler to the Butte City Gas Light Co., Montana, and have Swift & Co.'s contract for a Barr compound duplex pumping engine of 1,000 gallons capacity per minute. Their Lahman-Kirkwood shaking and dumping grates, American leather link belt, Hill clutch pulleys and couplings are very popular with operators of electric light and railway stations, and trade in their engineering specialties generally is quite good.

SUNBEAM INCANDESCENT LAMP CO.

The above company, of 805 Chamber of Commerce Building, has recently settled in new quarters larger than those heretofore occupied, where with specially designed apparatus and the best known modern equipments they are prepared to take care of their growing trade. Since June last until now they have been unable to fill all the orders that have come to them. This fact, which they regard as a fair indication of the merit of their lamp, has compelled them to carry out their plans for extension of facilities, referred to above.

MR. W. S. CHESLEY.

This gentleman, who has had experience in electric installation work, has recently opened an office at 171 Broadway, this city, where he proposes to do an electrical engineering business, including the installation of plants of all descriptions. In addition Mr. Chesley has undertaken the purchase and sale of all kinds of electrical apparatus, including second-hand electrical goods, such as dynamos, lamps, etc. Mr. Chesley's past experience well qualifies him for this work and as the handling of second-hand goods has thus far been entirely neglected in this vicinity, Mr. Chesley may confidently look for a large and growing trade.

THE WALKER ELECTRIC CO.

The Walker Electric Company, of this city, whose simple and ingenious meter is well known to our readers, have recently enlarged their offices and facilities and are doing a large and increasing trade. Their simple ammeters and voltmeters are meeting with favor in many stations and among those recently supplied are the Mt. Morris Electric Co., and C. & C. Electric Motor Co., of this city, the Elektron Mfg. Co., W. T. Goodnow, of Lebanon, Ky., the Holtzer-Cabot Co., of Boston, the Pacific Electrical Storage Co., of San Francisco, and a large number of others. The Walker electric meter, which gives a continuous photographic record of the consumption of current, is meeting with success as it overcomes the difficulties heretofore experienced in apparatus of this kind.

A DESIRABLE FACTORY.

Our electrical friends who are casting about for a suitable place for manufacturing their specialties should not fail to notice the illustrated advertisement of a machine shop in another column. We know the parties advertising, and can vouch for their entire respectability and responsibility for their statements. We are assured that it is an uncommon opportunity on account of the moderate rate of wages prevailing in the vicinity, low rent and general eligibility of location.

EDISON-LALANDE BATTERIES.

The Edison Manufacturing Co., of Orange, N. J., has issued a very handsome quarto catalogue and illustrated price list relative to its Edison-Lalande batteries. It has an unusually good introduction in the shape of a discussion of primary batteries, the points of superiority claimed for the Edison-Lalande being enforced by a number of diagrams and curves of tests. There are also a large number of fac-similes of testimonials from users of the battery, and some data as to specific employments for which it is well adapted. The second section consists of instructions as to setting up, with details as to sizes, prices, capacity, hours of running, etc. It is in fact the best battery pamphlet issued at the present time. Every point or argument that could be made in behalf of the battery is here set down strongly and clearly, and the whole is presented in most interesting and attractive form.

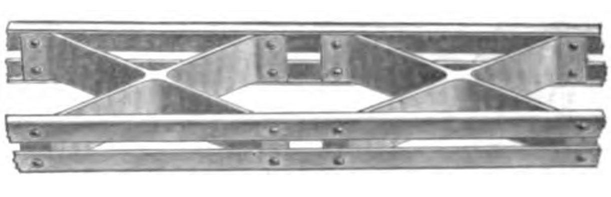


FIG. 2.—BROWNLEE ELECTRIC RAILWAY POLE.

THE PHŒNIX LAMP CO.

The above named company was incorporated December 31st in New Jersey, with a capital of $100,000, and will repair incandescent lamps. William Roessler, A. Greenberg, Ernest C. Keib, Lloyd M. Mayer and R. T. Macdonald are the incorporators.

THE DETROIT ELECTRICAL WORKS.

The Detroit Electrical Works are now ensconced in their mammoth new factory on Woodward avenue, and every department is in a continuous state of activity. Having recently had the pleasure of inspecting the factory we cannot express our appreciation too strongly at the way their work is carried on in its complete and thorough treatment of detail under the able guidance of Messrs. W. A. Jackson, C. A. Benton and Frank B. Rae. Amongst other apparatus ready for shipment, seven of the trucks for the electric street railway at Aurora, Ill., of the new Taylor pattern, manufactured by the Gilbert Car Co. and equipped with the 30 h. p. Rae motors now so well and widely known, and two of the four 80,000 watt generators, were especially noticeable, their excellent mechanical and electrical workmanship indicating high efficiency and great durability.

A novel departure has been made in illuminating and operating the machinery throughout the building. It is lit by incandescent lamps, which are run from the regular 500 volt street railway current furnished to the electric road which runs past the door; and each department is operated by a separate motor running on the same 500 volt circuit, thus demonstrating in the most forcible manner the perfect adaptability of the railway current for both lighting and power purposes. A quantity of special electrical machinery was also being tested before shipment for use in mining and other special work to be operated from street railway circuits. One feature of great and impressive interest is the fact that this company do all their work themselves, having their own foundry, making their own gearing, and last, but by no means least, insulating their own wire, to which latter point they attribute the fact that they have had no armature burn-outs, other than one which was caused by lightning. Their street railway system is now receiving in full measure the widespread attention and adoption which, from its features of simplicity, carefully worked out details and general excellence, it deserves.

DETROIT TRADE NOTES.

THE LOCKWOOD INSTRUMENT COMPANY are doing an active business in their central station measuring instruments. They have recently brought out and already sold a large number of new ammeter plug switches for arc switch boards for inserting the arm, etc., safely and expeditiously in the circuit. This was designed by Mr. Joseph E. Lockwood, and this device in its essential usefulness and reliability is a high tribute to his thoroughly practical inventive genius.

THE DETROIT DYNAMO CO. are pushed to their utmost capacity turning out their "King" dynamos for plating work, and are also manufacturing quite a number of lighting machines up to a capacity of 100 lights. They will probably considerably enlarge their facilities in the near future.

THE MARKLE ENGINEERING CO. are meeting with excellent success with their many electrical specialties, and "Stoddard" Rosette cut-outs are selling like hot cakes.

A. D. CAMPBELL, one of the pioneers in electrical construction work, is kept right at it and continually adding to his record of the number of lamps he has put in, wired, changed around, taken out and so forth, which has reached some astounding figures now and shows that Detroit has a very fair share of incandescent lighting and perhaps a greater number for its size than any other city.

THE DETROIT MOTOR CO., whose machines have made such a favorable record in the electrical field, are turning out at their large new factory at Cass avenue and the railroad a larger quantity of their motors and also of their new generators, recently illustrated in our columns, both of which are the work of Mr. Harry Blades, the electrician of the company, and which in their appearance and operation evince his high skill as a designer of electrical machinery.

THE FISHER ELECTRICAL CO. report business in construction and installation work as good. The Fisher dynamo is of quite unique construction, being wound with 3 coils, that at the neutral point of the field magnets being the shunt coil and the other two around the polar projection at the most efficient point, the series coil; and it is so perfectly compounded that all the lights but one can be thrown off at the same instant without a flicker on the solitary one in circuit or a spark at the brushes, which are fixed in one position on the commutator and need no adjustment, no matter how the load varies. Mr. Fisher has several of these machines of large capacity ready for shipment and is building several more.

THE COMMERCIAL ELECTRIC CO., who handle electric light power and all kinds of supplies, are well loaded with orders for all classes of goods and are doing a constantly and rapidly increasing business.

MR. JOSEPH E. LOCKWOOD, of Detroit, who recently resigned from the managership of the Brush Electric Light Co. there, has not as yet made any permanent connection with any company, although he has had numerous flattering offers. He is engaged just now in designing a special switch board for the Narragansett Electric Light Co., of Providence, R. I., for their alternating system and will embody in it quite a number of novel and advantageous ideas. He is also doing some special engineering work for the Detroit Motor Co.

THE DETROIT SHEET METAL AND BRASS WORKS are manufacturing a new and very efficient dynamo and will undoubtedly meet with the best of success, as their machines are of substantial build and scientific design with many important improvements in detail. They are also preparing to furnish a direct driven equipment for ship work of a most reliable and excellent character. Their apparatus is being designed by Mr. Fuller, who has certainly made some very progressive departures in his work.

THE MICHIGAN ELECTRIC CO., who have been doing a large business in repair work, have some new things in store for the electrical field, and will add facilities to enable them to cope with the growing repair business and to carry out manufacturing work on an extensive scale.

NEW ENGLAND TRADE NOTES.

THE BERLIN IRON BRIDGE CO., of East Berlin, Conn., are making a specialty of iron roofs for electric light and power stations, and are acquiring a well deserved name for their light and graceful structures. Probably the largest and most important roof which they have yet built for this purpose is the one for the Narragansett Electric Light Co., of Providence, though they have since fitted up many others, and have a large amount of similar work on hand now. They have issued two very complete and interesting catalogues with excellent cuts showing in detail a few of the roofs which they have recently built. A careful perusal will well repay every electrical engineer engaged in designing central stations.

THE EASTERN ELECTRICAL SUPPLY & CONSTRUCTION CO., of Boston, have been appointed general Eastern agents for the Card Electric Motor and Dynamo Co., of Cincinnati, O. These motors, which were recently illustrated in our columns, are made for use on both arc and incandescent circuits, and run from ¼ to 30 h. p. They have also recently become exclusive agents for the Erickson insulating coupling and the Happoldt cut-out, a device for cutting out electric gas lighting batteries when a ground or short circuit occurs.

THE OTIS ELEVATOR CO., through their branch office at 72 Mason Building, Boston, are installing an electric elevator in the Shawmut Building, 146 Franklin street, Boston, for Rodgers, Burdett & Co. An 8¾ h. p. Eickemeyer motor is used, and it will lift a total weight in the elevator of 1,500 pounds at the rate of 250 feet per minute. The motor is fitted with an automatic regulator and is operated by a lever in the car. In the car also is an indicator for telling which way the machine is set, so that the operator can tell whether it is set for going up or down. The motor is geared with one reduction to the hoist by means of a worm and worm wheel, and is connected to the ordinary 220 volt Edison underground system.

THE JOHNSTON ELECTRIC TRAIN SIGNAL CO. have removed their headquarters from 620 Atlantic avenue, Boston, to Woburn, Mass., where their factory is situated. Mr. G. S. Russell, of Marlboro, has been elected assistant treasurer of the company.

WESTERN TRADE NOTES.

MR. G. A. EDWARD KOHLER will continue as Western agent for the Eddy Motor Co., of Manchester, Conn., they having decided to retain the services of so excellent and successful a representative, and will not join the Illinois Electric Material Co., as stated, this company having released Mr. Kohler to continue in his former line.

THE GREAT WESTERN ELECTRIC SUPPLY CO. report business for the New Year as starting out with remarkable briskness, and the indications are that they will do a larger business than ever during the ensuing year. They are making arrangements to place on the market a number of new specialties in lighting and railway supplies of the higest merit.

A. L. IDE & SON, the well known engine builders of Springfield, Ill., are doing a very brisk business, and their new tandem compound engines are meeting with that extended success and adoption which such an excellent and highly efficient engine deserves. They are just shipping 7 150 h. p. Ideal tandem compound condensing engines for the Davenport & Rock Island Street Railway Co. The power plant will be located in Rock Island, Ill., and supply power for this company's lines in the three cities of Davenport, Rock Island and Moline.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

Electrical Engineer.

Vol. XI. FEBRUARY 4, 1891. No. 144.

THE INVENTORS OF THE ELECTRIC MOTOR.—V.

WITH SPECIAL REFERENCE TO THE WORK OF THOMAS DAVENPORT.

BY

Franklin Leonard Pope

(Conclusion.)

THE narrative of the active life and labors of Thomas Davenport in the field of electro-magnetism and its application as a motive power, has now been brought to a close. It only remains for me to sum up, so far as may be, what I conceive to be the true significance of his work as a part of the general history of the industrial application of electro-magnetism, and by way of preface, to say a few words regarding the personal characteristics of the man.

Although forty years have passed since Davenport was borne to his humble grave under the shadow of the stately elms of Brandon, there are still living many old residents, his former friends and neighbors, who well remember him, and who by common consent, speak of him as one who received, and who in the fullest measure deserved, the respect and esteem of the community in which he lived. However visionary his schemes may have appeared to many of his townsmen, there seems to have been but one opinion as to the high character and substantial worth of the man himself.

Thomas Davenport was pre-eminently a student, a thinker and an originator; a strikingly characteristic type of a class of minds to whom the world always has been, and always will be, indebted for its grandest mechanical conceptions. Modest and unassuming in his intercourse with his fellow men, reticent in speech, but cheerful and kindly in manner, and by no means lacking in that dry humor which seems almost inseparable from such a nature, he nevertheless possessed, beneath a peculiarly mild and gentle exterior, a determined and resolute perseverance but little removed from obstinacy, which poverty, adversity and disappointment were utterly powerless to overcome.

From the very moment when he first witnessed the exhibition of the mysterious power of Henry's electro-magnet, the conception of utilizing its invisible force for the propulsion of machinery took possession of his mind and thenceforth occupied it almost to the exclusion of every other consideration. He studied, he pondered, he experimented. Seeking from the beginning to produce continuous rotary motion, with the unerring instinct of the born inventor, in his very first essay he grasped what I have defined as the essential principle of the electric motor, the combination of moving and fixed electro-magnets, one reversible and the other non-reversible; and however extensively and widely he may subsequently have experimented in other directions, he never once loosed his grasp of this fundamental conception.

It may be asked whether it is certain that this conception is due to Davenport alone. It is true that in an absolute sense, this question at this late day can only be answered by the light of internal evidence. Every one who has much intercourse with inventors must have observed that when two minds have wrought upon a mechanical problem until success has crowned their efforts, it is ordinarily quite impossible even for the parties immediately concerned to dissever and distinguish their respective contributions to the general result. Yet the experienced observer, familiar with the mental characteristics of the varying types of the creative mind, usually finds little difficulty in reaching a conclusion which is at least satisfactory to himself. He only needs to know the two men to know in what manner and by what mental processes the ultimate result must have been reached.

From the moment that Davenport declared, in the presence of the little assemblage at Crown Point, his intention of producing rotary motion by means of electro-magnetism, it is certain that he never for one moment permitted himself to doubt that he would ultimately accomplish that result. He was fortunate in having a coadjutor like Smalley, young, enthusiastic, a natural mechanic and a willing worker; and it is altogether probable that to the latter is largely due the embodied form and structure of the machine, particularly the contrivance of the mechanism employed for effecting the reversal of the current which is shown in the sketch accompanying the specification of 1835. It is not unlikely that the design of the first metallic commutator may also have been due to him; but the fact remains, that the master mind, wholly absorbed in the subject, and possessing the determination and the capacity to succeed in spite of every obstacle was that of Davenport. Had Smalley not been at hand to assist him, some other person would have been found. Had it been necessary for him to carry on his work alone, he would have done it. When a mind possessing the indomitable perseverance of that of Davenport, is once in possession of an original idea—the conception of something to be done—its ultimate accomplishment, whether with or without the assistance of others, is as certain as fate. It is the story of every great invention; poverty, ridicule, discouragement, may defer, but are powerless to prevent, the development of an idea.

In the argument before the Supreme Court of the United States in the Telephone case, the learned counsel for the complainant remarked:—

> It is of common experience that the maker of a great invention which originates a new art, seldom has the technical skill and turn of mind which produces the best apparatus. . . . It is an interesting fact that the particular forms Watt thought of when he took out his patent, were practically so ineffective that it required ten years' unremitting work of himself and Boulton, the best machinist in England, before an engine was produced which was commercially satisfactory. But since he took his patent, no engine has ever been constructed which condensed the steam in the working cylinder.

Many instances might be cited as evidence as the truth of this statement. Not only Watt, but Fulton, Morse, Bessemer, Bell, and to mention a very recent instance, Rogers, the inventor of the wonderful typograph machine, were men of only ordinary mechanical skill, and were almost wholly indebted to others for devising and working out the mechanical contrivances in which their conceptions were embodied, and by which only their work could be rendered useful to mankind. Yet this fact does not in the least detract from their individual merit as inventors of the highest type, and as benefactors of the human race. I have seldom seen this idea more forcibly expressed than in a decision of Judge Kane, rendered many years ago in an important patent case, in which he said:

> All machines may be regarded as merely devices, by the instrumentality of which the laws of nature are made applicable and operative to the production of a particular result. He who first discovers that a law of nature can be so applied, and having devised machinery to make it operative, introduces it in a practical form to the knowledge of his fellow men, is a discoverer and inventor of the highest grade—not merely of the mechanism, the combination of iron, brass and wood, in the form of levers, screws and pulleys, but the force which operates through the mechanical medium—the principle—or to use the synonym given for this term in the act of 1793, the *character* of the machine, ... the essential principle which his machine was the first to embody, to exemplify, to illustrate, to make operative, and to announce to mankind.

I have expressed the opinion that the combination of the moving and fixed electro-magnets, one reversible and the other non-reversible, must be regarded, in the light of our present knowledge, as the essential principle of the electric motor. The experience of the past few years has demonstrated beyond question, that the largest motors yet made, show as high, if not a higher, net efficiency than the smaller sizes, and in fact it has not as yet been found practicable to construct an efficient motor of any considerable power upon any other principle. A moment's reflection serves to show the impracticability of organizing a large motor, either with permanent magnets as in Sturgeon's plan, or with non-reversible electro-magnets and neutral armatures as in Edmondson's plan, while on the other hand, by employing the principle introduced by Davenport in his pioneer machine of 1834, no apparent limit to the dimensions or power of the motors which it is possible to construct has yet become manifest.

In our own time, when the doctrine of the conservation of energy is so inseparably interwoven with every conception of the mechanical and chemical interactions of the natural forces, it is wellnigh impossible for us to realize that in Davenport's day, this fundamental law was wholly unknown, or at most had been only dimly perceived by one or two of the most profound philosophers of the day. Davenport himself lived and died in the full conviction that the day which should witness the triumph of electro-magnetism over steam was close at hand. There is much reason to hope that ere many years have passed, his cherished belief and expectation will prove to have been not wholly without foundation. Undoubtedly he also believed that voltaic energy was in like manner destined to take the place of coal energy. In his time science had not sufficiently advanced to enable the latent fallacy of this idea to be detected and demonstrated. It is not to have been expected that a humble village artisan, knowing literally nothing of science beyond that which his own discoveries had taught him,[1] should have mistrusted the existence of a law of equivalence between the forces of nature, which was as yet undiscovered and even unsuspected by the most learned philosophers of the day. The following extracts, selected at random from many which might be cited, give ample evidence of the views which generally prevailed among scientific men in relation to this subject, prior to the year 1840. In his treatise on the steam engine, then recently published, and considered a work of high authority, Dr. Lardner had said :—

> Philosophy already directs her finger at sources of inexhaustible power in the phenomena of electricity and magnetism, and many causes to combine to justify the expectation that we are on the eve of mechanical discoveries still greater than any which have yet appeared ; and that the steam-engine itself, with the gigantic powers conferred upon it by the immortal Watt, will dwindle into insignificance in comparison with the hidden powers of nature still to be revealed, and that the day will come when that machine, which is now extending the blessing of civilization to the most remote skirts of the globe, will cease to have existence except in the page of history.

At the meeting of the British Association in 1840, Prof. Jacobi presented to that body a very carefully prepared paper "On the Principles of Electro-Magnetical Machines," in the concluding portion of which he said :—

> I consider that there will not be much difficulty in determining with sufficient precision the duty of one pound of zinc, by its transformation into the sulphate, in the same manner that in the steam engine, the duty of one bushel of coal serves as a measure to estimate the effect of different combinations. The future use and application of electro-magnetic machines appears to me quite certain, especially as the mere trials and vague ideas which have hitherto prevailed in the construction of these machines have now at length yielded to the precise and definite laws which are conformable to the general laws which nature is accustomed to observe with strictness, whenever the question of effects and their causes arises.[2]

The eminent English philosopher, James P. Joule, of Manchester, in a communication containing an account of some of his quantitative experiments and investigations in electro-magnetism, expressed himself as follows :—

> I can scarcely doubt that electro-magnetism will eventually be substituted for steam in propelling machinery. If the power of the engine is in proportion to the attractive force of its magnets, and if the attractive force is as the squares of the electric force, the economic effect will be in the direct ratio of the quantity of electricity, and the cost of working the engine may be reduced *ad infinitum.* It is to be determined, however, how far the effects of magnetic electricity may disappoint these expectations.[3]

So late as 1851, Professor Page, in discussing the question of the relative cost of steam and electric power, as affected by the then recent investigations of Joule, remarked :—

> We have no proof of any such relation of electricity to heat as to make the mechanical power of one the measure of the mechanical power of the other. Whatever may be the connection and analogy between heat and electricity, we must consider them as distinct forces in their mechanical relations.[4]

The subsequent researches of Grove, Mayer, Liebig, and more particularly of Joule himself, ultimately established the law of the equivalence of forces upon the firm and enduring foundation of experimental demonstration, and confirmed the opinion long before expressed by Henry, that the endeavor to find in voltaic electricity a substitute or a rival to coal-power, must, from the nature of things, be an utterly hopeless one.

The publications made by Professor Page at various dates between 1837 and 1855, and the interesting correspondence between Page and Davenport which has already been given, show that the conceptions of the two men, both in respect to the most desirable principle of construction of the electro-magnetic motor, and as to the possible limits of its power, were widely at variance ; but time, which proves all things, has shown conclusively, that of the two, the views of Davenport were the more correct. The opinions of Page are indicated in the extracts which follow, taken from articles written by him at various times :

> Since the announcement of Mr. Davenport's invention, the innumerable experiments which have been performed in this country, in England, on the continent of Europe, and even in the East Indies, have all contributed to prove that the smallest engines which have been made, have had by far the greatest proportionate power. Since I first gave the subject any attention, I have had sixteen different models constructed, each involving distinct principles. From all these experiments the inference is still the same, viz., the fewer the magnets and the smaller their size (within certain limits), the greater the ratio of mechanical power obtained.[5]
>
> Practically we have already been taught, that (unlike other powers, where the largest engines are the most simple and least expensive) electro-magnetic engines, above a certain limit, increase in complication and expense and in a much greater ratio than the power obtained. *To ascertain this limit, the precise point where economy ceases, is now the great, and ought to be the only, object of research.*[6]
>
> I must premise here (as I have heretofore expressed myself) that I *do not suppose this power capable of indefinite increase,* and in giving this description to the public, I am only selecting from the multitude of machines I have constructed, such forms as obviously economize a given galvanic power. A number of ma-

Drawing Accompanying Davenport's British Patent.

[Made to scale from actual Working Machine.]

Fig. 1, elevation.—Fig. 2, plan.—Fig. 3, vertical tranverse section.—Fig. 4, horizontal transverse section in plane of *a b.* of Fig. 3.—Fig. 5, plan of arrangement of magnets.

B platform; C base; D battery, consisting of concentric cylinders of copper E and zinc F, immersed in vessel G containing sulphate of copper solution; H I, positive and negative conductors; K L insulated commutator segments fixed upon vertical shaft R. M N O P cores of electro-magnets; Q Q Q Q helices of insulated copper wire; *a b* bearings of shaft R. *c d e f* commutator springs; V support for electro-magnet; S T semi-circular permanent steel magnets; 5 5 north poles and 6 6 south poles of permanent magnets.

> chines wherein *the poles of the magnets were changed*, and others wherein the poles of the magnets were not changed, but both systems, the stationary and the revolving, were rendered magnetic and non-magnetic at intervals, *have been laid aside as not worth describing.*[7]

So also in his letter to Davenport of April 28, 1838, he says :—

> I feel very sure the power will be useful to the extent I have above named (a power equivalent to one or two men), but for reasons which I can make conclusive to any one, *I do not believe in its indefinite increase.*[8]

The subsequent comment of Davenport upon this opinion, is a peculiarly significant one. In his letter to Page of October, 1850, he says :—

> Since I first saw the power of the electro-magnet exhibited, any idea that the power could not be indefinitely increased, seemed to affect me with a peculiar disagreeableness.

So also in his letter to Smith in 1839, he had said:—

> I have no doubt but that *the power is unlimited*, which can, and ultimately will, be successfully applied to all purposes for which steam power is now used.[9]

This difference of opinion was radical, and it extended to the details of the method of applying the electro-magnetic power. In his letter of April 28, 1838, Page says: "My main object has been to prevent retardation or back action. My plan is to cut off the galvanic current from both systems of magnets instead of changing poles as they arrive at equilibrium. The advantage of this I have fully tested."[8]

In an article written a year later, he remarks :—

> Change of poles cannot be introduced in a machine, for the following reasons :—1. It requires time; and during this time, the magnets which change poles are attracted and retained (retarded?) somewhat by those which do not change. 2. Similar poles will attract and produce back action; for unless the magnets which change poles be favored by excess of battery or superior conductors, they cannot receive near the same charge as those which do not change: for first, there is magnetism of an opposite character to be overcome; and secondly, two breaks in the galvanic circuit are necessary to produce change of poles. 3. Two magnets which have a statical repelling power, that is, a power which will merely keep them asunder when the machine is at rest, will attract each other when the machine is in motion. This singular fact is a consequence of secondary currents.[10]

So far as I have been able to ascertain, the views of Professor Page in this particular, remained unchanged throughout the whole course of his subsequent experimental labors. In every attempt made by him to produce electromagnetic power on anything like a large scale, as, for example, in his locomotive, and in the other experiments made under the Congressional appropriation, he appears to have consistently adhered to the theory that the best results were to be attained by simply cutting off the current from the magnets, without reversing polarity. Davenport, on the other hand, with equal persistency, adhered to the plan of reversing the polarity of one set of magnets twice in each revolution, and out of the very large number of machines constructed at different times by him or under his direction, the only instance I can find in which this principle was departed from, is in the case of the two or three helix machines which were built in New York between 1838 and 1840.[10a] The results of modern research and experience, have abundantly verified the correctness of Davenport's ideas, and have shown that the "peculiar disagreeableness" with which the notion of an assignable limit to the power of electro-magnetism affected him, was but a prophetic manifestation of the instinct and inspiration of the true inventor.

The course of Davenport and Cook in transferring their invention to an incorporated company, for the avowed purpose of raising money by the sale of shares to reimburse them for their expenditures, and to provide means for conducting further experiments on a scale large enough to demonstrate the utility of the invention, met at the time with a considerable amount of adverse criticism, an example of which among many others may be found in a paper on Electro-Magnetism as a Motive Power, by Professor Page, published in 1839, from which the following is an extract :

> It is much to be regretted, that in our country the invention should be a subject of mercenary speculation, when in reality it has no value except as an experiment, and that the public have been so far misled, as to withdraw that countenance and encouragement which the experiment really merits. We cannot but deplore, that such an interesting branch of science should be so traduced, and that the very name of electro-magnetism should be coupled with empiricism.[11]

So also, a prominent scientific journal in an editorial paragraph, observed:—

> We rather regret that this interesting application of electro-magnetism is attempted to be sustained by an appeal to the hope of immediate profit.[12]

I cannot but regard this implied censure as unjust and unmerited. Examine critically as one may every line of the correspondence and writings of Davenport and I venture to say there can be found not one trace of a self-seeking spirit, not the faintest expression of a desire to make money from his invention, beyond the modest and reasonable expectation of a comfortable support for himself and those dependent upon him. It is but seldom that he refers, even casually, to the innumerable hardships and inconveniences which he and his family must have not infrequently suffered from want of means; but on the other hand, we find more than once, expressions of profound regret at being unable to command the financial support which was essential to him in perfecting and carrying out his self-imposed task of giving to the world an economical and efficient substitute for what he calls, and was at that time justified in calling, "the murderous power of steam." For my own part, I can see no reason why the action of Davenport and Cook, in taking part in the organization of a stock-company whose earnings were expected to come from the future development of the invention, was not in every respect as legitimate and proper at that day as it would be at this. It is certain that neither of the principals could have entertained the slightest intention of misrepresenting the circumstances, or of misleading the public. It appears to have been perfectly well understood by all concerned, that the invention was not claimed to have passed beyond the stage of a promising experiment, but nevertheless, that if the proceeds of the sales of stock enabled a large engine to be constructed and put in successful operation, the future of the enterprise might reasonably be expected to be highly profitable to the shareholders. It is not impossible that misrepresentation and even fraud may have been practiced upon some of the shareholders by the agent who had been entrusted by Davenport and Cook with the management of the business of the company, but the records show that no effort was spared by them to put a stop to his irregular proceedings as soon as they became aware of them. One needs but to read the letters of Davenport, to be impressed with the conviction that he was a man of childlike simplicity and transparent integrity of purpose, and that the single object to which he devoted every energy of his life, was not the accumulation of money nor the gratification of self, but the development of what he believed to be an invention destined to confer priceless benefits upon his fellow men.

In conversation with some of the more elderly residents of Brandon, among whom were a number of acquaintances and friends of Davenport during his lifetime, I have been more than once assured that he was the real originator of the electric telegraph. This statement has recently been made with some particularity in the columns of the local press :

---

[7] *Amer. Jour. Science*, xxxvi., 350 (1839).

[8] *Ante*, p. 71.

[9] *Ante*, p. 94.

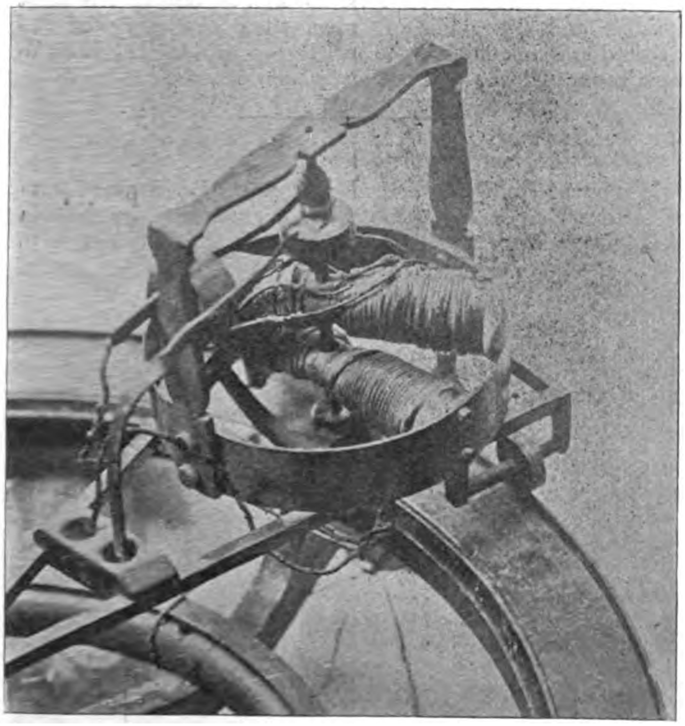
[10] *Amer. Jour. Science*, xxxv, 109 (1839).

[10a] It does not appear that Davenport ever took out a patent in this country on the helix machine. It was, however, patented in Great Britain, as a communication from abroad, on July 11, 1838, by Lewis C. Callet.

[11] *Amer. Jour. Science*, xxxv., 107.

[12] *Ibid.*, xxxiii, 194.

> [*From the Brandon* (*Vt.*) *Union, December* 19, 1890.]
>
> There are but very few outside this immediate vicinity that are aware of the fact that the first telegraph line in the world for transmitting signals over a wire by electricity was erected in Brandon, and by a Brandon man. Yet such was the case, and this town has the honor of being the first spot where this mighty invention of modern times was put to practical use. . . . Mr. Davenport, then living in Brandon, in connection with Mr. Smalley, now living at Forestdale, experimented considerable in electric appliances. Long before Prof. Morse had projected anything of the kind, these gentlemen had a wire that connected their two residences, on which were transmitted dispatches by means of electricity, using a battery, and which gave by machinery the sound as now heard from machines in ordinary use. After this wire had been in operation for some length of time, Mr. Davenport moved to New York and began the publishing of the *Electro-Magnet*, being printed by a machine propelled by electro-magnetic force, as the paper claims upon its title-page. While in New York we are informed that Prof. Morse called upon Mr. Davenport, and was struck with his discovery, and then began to make improvements thereon, inventing the Morse alphabet. He then applied it to Mr. Davenport's discovery which has proven to be such a magnificent success. To Prof. Morse belongs a great deal of honor for bringing before the public the wonderful merits and advantages of telegraphy, but the discovery and origin of this great invention justly belongs to Thomas Davenport of Brandon.



WORKING MODEL OF DAVENPORT'S ELECTRIC LOCOMOTIVE.

[*Photograph from the Original in the Cabinet of the Troy Female Seminary. Supposed to have been constructed circa* 1837.]

No claim of this kind is asserted or even remotely hinted at in any of the letters or papers of Davenport which I have examined. On the other hand, in response to a specific inquiry as to the telegraph line which Davenport and himself are reputed to have constructed and used, Mr. Smalley has stated that in the course of their experiments in 1834, they discovered that physical effects could be produced by the electro-magnet through a considerable length of wire, and that any length at their command seemed to make no difference in the *time* required to effect the result, but that no attempt was made by them to transmit intelligible signals, or to construct apparatus for that purpose. The fact first mentioned by Mr. Smalley, was, however, well known at the date mentioned (1834), having been fully demonstrated in the experiments made by Henry in Albany in 1830–31.

The source of this telegraphic legend may undoubtedly be traced to a conviction which Davenport is known to have entertained, and honestly so, that Morse's telegraphic apparatus was an infringement upon his own patent of 1837. In a letter written from Brandon, under date of April 18, 1846, to Dr. Thomas P. Jones, of Washington, he writes :—

> I learn from Mr. ——— who has recently been in Washington, that it is your opinion that Prof. Morse's application of electro-magnetism to propelling his machinery for the telegraph is an infringement on my patent. I have long thought so myself, but not knowing how to proceed in consequence of my poverty-stricken situation, I have taken no steps in the case. . . . As the claim granted me is for "applying magnetic and electro-magnetic power as a moving principle for machinery," it is as clear as the solar light that Morse must be using what of right belongs to me.

In explanation of this erroneous opinion on the part of Davenport, it must be borne in mind that at the date when the above letter was written, the history and chronology of the invention of the telegraph had never been made public ; it was first brought out in the course of the exhaustive legal investigations consequent upon the interference proceedings between Morse and Bain, and the suits against O'Reilly and others by the Morse patentees at a still later date. The very earliest published notice of Morse's invention appeared in the New York *Journal of Commerce ;* a communication over Morse's own signature, accompanied by a sample of the writing of the apparatus then used, which was dated September 4, 1837. As this was some two or three months after his visit to Davenport's laboratory, the latter, by a very natural process of reasoning, assumed that Morse had merely applied his (Davenport's) idea to the movement of another kind of machinery for a different purpose. But at a later date it was established, upon evidence which cannot be gainsaid, that Morse had actually constructed and operated his electro-magnetic recording apparatus in a short circuit in his rooms in the New York University building, as early as November, 1835, more than a year before Davenport and Cook came to New York with their machinery for exhibition.[13]

It is not improbable that Morse was indebted to Davenport for a more effective construction of the electro-magnet than he had hitherto employed, but even granting this, the electro-magnet was a feature which Davenport himself had borrowed from Henry, and which formed no part, *per se*, of his own discoveries.

The patent of Davenport was granted February 25, 1837, under the title of "An Application of Electro-Magnetism to Propelling Machinery." The claiming clause of this patent has been criticised by unfavorable implication, as "a remarkable instance of the granting of a broad claim by the Patent Office to an inventor." It may not be out of place to consider for a moment whether such a criticism is well-founded. The statement is in the following words :

> The discovery here claimed and desired to be secured by Letters Patent, consists in applying magnetic and electro-magnetic power, as a moving principle for machinery, *in the manner above described*, or in any other substantially the same in principle.

Within a few months after the issue of the patent, Davenport, referring to his invention, wrote :

> No departure from the principle of the orginal invention has been or can be made. That principle was *the production of rotary motion by repeated changes of magnetic poles ;* this it is which is secured by patent ; and no peculiarity of arrangement or modification of the magnets can be made to move without adopting the essence of the first invention.

This assertion, although in a strictly literal sense inaccurate,[14] is nevertheless substantially true, inasmuch as every practical motor in use at the present day involves the principle of the "production of rotary motion by repeated changes of magnetic poles." If, therefore, we read into the claim of the patent the mode of operation original with Davenport, viz., the combination of reversible and non-reversible "galvanic magnets" which is described in the specification, as being the organization referred to in the words "in the manner above described," we find that its manner is not only not unwarrantably broad, but that it defines with accuracy and clearness the precise invention which Davenport made; no more; no less.

---

[13] In the case of Morse *v.* O'Reilly in the United States Supreme Court, the following witnesses testified to having seen the operation of Morse's electro-magnetic recording telegraph in his rooms in the New York University in 1835 and 1836 : Leonard D. Gale, Daniel Huntington, Osbert B. Loomis, and Robert Rankin.

[14] Neither the prior machine of Edmondson already described (ante, p. 1) nor the helix and core machines, subsequently constructed by Davenport himself and by Prof. Page, make use of the principle of "repeated change of poles." But none of these types of machines have achieved permanent industrial success, in comparison with the pole-changing type, for reasons which are now well understood.

Justice Curtis, in his decision in a leading patent case before the Supreme Court of the United States, has remarked:

> It is this *new mode of operation* which gives it the character of an invention and entitles the inventor to a patent; and this new mode of operation is, in view of the patent law, the thing entitled to protection. . . . . . . Specifications are to be construed liberally, in accordance with the Constitution and the patent laws of the United States, to promote the progress of the useful arts, and allow inventors to retain to their own use, not anything which is a matter of common right, but what they themselves have created.[15]

"In that case," says James J. Storrow, confessedly one of the most learned and able advocates of our own day, "the maturest judgment of the Court was announced by a jurist whose peculiar faculty it was to perceive both the groundwork of a legal rule, its limits, and the limits of its application, and to formulate the whole in language which defined as well as stated." And in a more recent case decided in the same court the venerable Justice Bradley has remarked:

> The whole subject-matter of a patent is an embodied conception, outside of the patent itself, which to the mind of those expert in the art, stands out in clear and distinct relief, whilst it is often unperceived, or but dimly perceived, by the uninitiated. *This outward embodiment of the terms contained in the patent is the thing invented,* and is to be properly sought, like the explanation of all latent ambiguities arising from the description of external things, by evidence *in pais.*[16]

If, therefore, we interpret the claim of Davenport's patent, not only in its relation to the state of the art at the date of its invention, but in the light of the well-considered utterances of the highest tribunal of the land, and compare it thus understood with the definition of the fundamental principle of the modern electric motor which was formulated at the beginning of this series of papers, we shall find that they are substantially identical. The conclusion necessarily follows, that the invention thus identified was conceived and embodied in concrete operative form by Thomas Davenport at least as early as July, 1834, was exhibited and described to others prior to January 5, 1835, and was covered by his Letters Patent of February 25, 1837. If, therefore, this patent, which expired in February 1851, were in force to-day, it is not too much to say, that upon a fair judicial construction of its claim, every successful electric motor now running would be embraced within its scope.

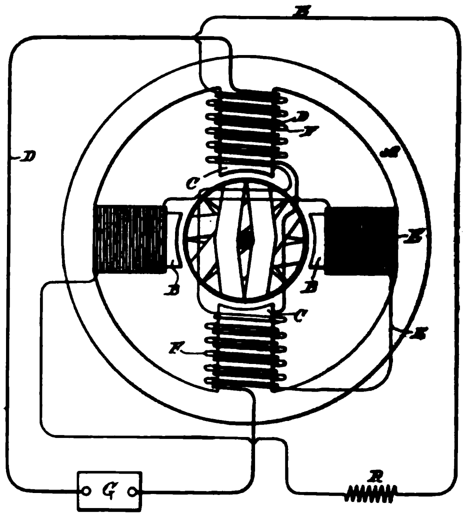
Thomas Davenport was born in Williamstown, Orange County, Vermont, on July 9, 1802. He was descended from the family of the same name prominent in the early annals of the New Haven colony, and was the eighth in a family of eleven children of Daniel and Hannah (Rice) Davenport. His father, who was a farmer, died when he was but ten years of age, leaving the family in indigent circumstances. At the age of 14 he was apprenticed to Samuel Abbott, of Williamstown, with whom he learned the blacksmith's trade. Upon the expiration of his apprenticeship, about 1823, he removed to Brandon, Vt., where he set up business for himself. He married, February 14, 1827, Emily, daughter of Capt. Rufus and Anna Goss, of Brandon, born March 29, 1810. The mother of Rufus Goss was a daughter of the celebrated American traveler, Jonathan Carver. Davenport was prosperous in his business, and shortly after his marriage, built a commodious brick house in Brandon village, and was in a fair way to accumulate a comfortable property, when his attention was directed by the circumstances already related, to the study of electro-magnetism. From that time forward, the history of his labors and the history of the man are inseparable.

Two sons were born to Davenport, both of whom subsequently enlisted and became officers in the war of the rebellion. The elder, George D., a captain in the 5th Vermont Regiment, fell in the battle of the Wilderness; and the younger, Willard G., who is still living, became a clergyman in the Protestant Episcopal Church. The story of the active life of the inventor has been fully told in connection with the history of his work. He died on a small farm in Salisbury, Vt., July 6, 1851, at the comparatively early age of 49, and was buried in Brandon. The immediate cause of his death appears to have been a species of nervous prostration, superinduced by excessive study; and no doubt aggravated by the effects of so many years of toil, privation and disappointment.

If the publication of these papers shall in any measure serve to render tardy justice to the memory of one of the most meritorious of inventors, as well as one of the most amiable and deserving of men, then the story of the "Brandon blacksmith," the writing of which has been to me a labor of love, will not have been in vain.

NEW TESLA ALTERNATING MOTOR.

We have already described a number of different forms of alternating current motors designed by Mr. Nikola Tesla, depending upon a variety of phenomena met with in the employment of alternating currents. One general type of these consists of a machine with, say, four poles, between which is mounted an armature, generally wound with closed coils. On two opposite poles of the field are primary coils connected up in the main circuit. On the same cores are also wound secondary coils which are closed through coils on the other pair of poles. When an alternating current is caused to pass through the primary coils, it energizes directly one set of poles, and induces currents in the secondary coils, which in turn energize the other poles; but the phases of the current in the secondary coils may differ in time from those of the primary current, and hence a shifting of the poles is effected, that imparts a rotation to the motor.



Tesla Alternating Motor.

In the new motor designed by Mr. Tesla, however, two energizing circuits are brought into inductive relation in the motor itself, and the employment of an external induction device is thus avoided. The operation is dependent upon the existence of a certain difference of phase between the currents of the primary and secondary coils, and will be readily understood by reference to the accompanying diagram.

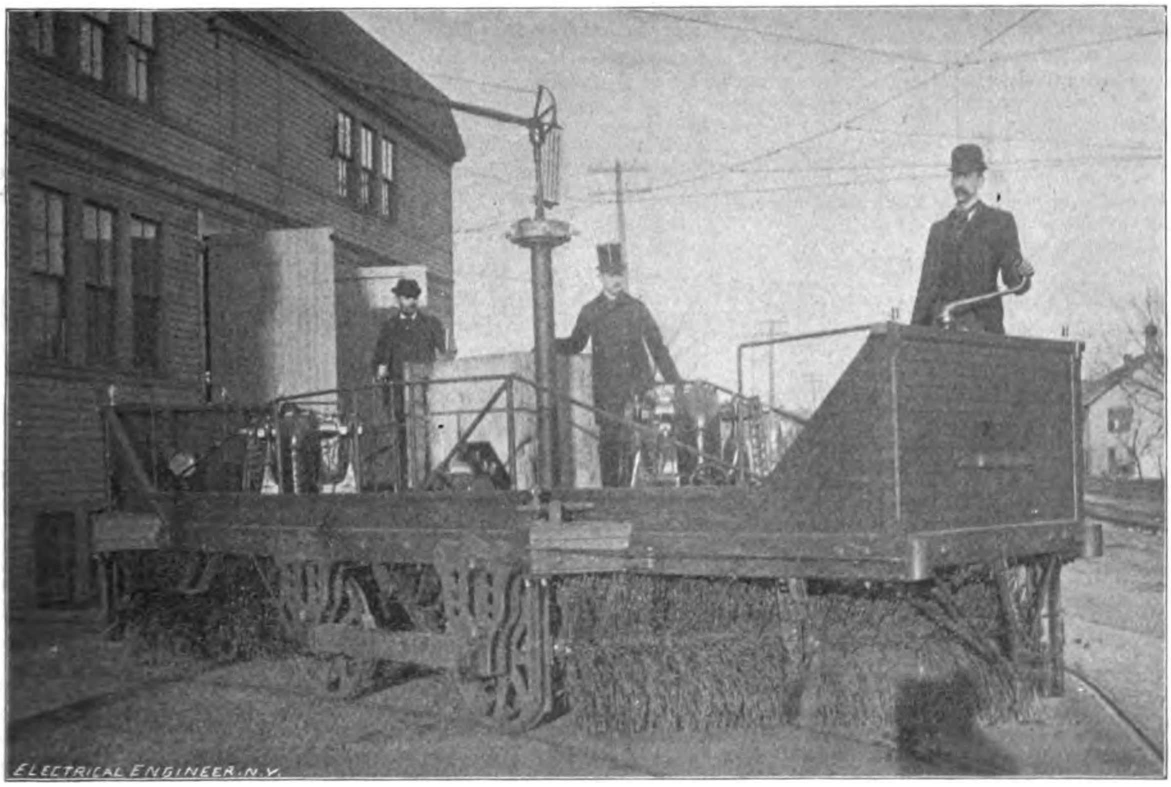
---

[15] Winans v. Denmead, 15 Howard, 330 (1853).
[16] Bischoff v. Wethered, 9 Wallace, 812 (1869).

Here A represents the field magnet of a motor, which is built up of sections or plates. B and C are polar projections upon which the coils are wound. Upon one pair of these poles, as C, are wound the primary coils D, which are directly connected to the circuit of an alternating-current generator. The secondary coils, F, are wound on the same poles with the primary, and connected with other coils, E, which surround the poles B.

The current in both the primary and secondary coils will lag behind the impressed electromotive force, but to secure the proper difference in phase between the primary and secondary currents themselves, the resistance of the circuit of the secondary is increased, so as to reduce as much as possible its self induction. This is accomplished by making the coils E of comparatively small wire, having but few turns around the cores, or by inserting in the secondary circuit an artificial resistance, R.

In practice, it has been found desirable to wind the armature with closed coils, in which currents are induced by the action of the primaries.



COLUMBIA ELECTRIC SNOW SWEEPER, ST. PAUL, MINN.

THE COLUMBIA ELECTRIC RAILWAY SNOW SWEEPER.

The severe winters met with in our climate make an efficient snow-sweeper a most important adjunct to the equipment of an electric railway. As a successful example of this kind we give in the accompanying engraving a view of a new snow sweeper built by the Columbia Electric Co., of St. Paul, Minn., for the St. Paul & Minneapolis Railways.

The car frames of the sweeper were built by the St. Paul City Ry. Co. and the motors by the Columbia Electric Co. The car is driven by one 30 h. p. laminated field, Gramme ring motor, connected by sprocket gear to the axles of the car. Friction wheels may be used, as shown in the engraving, but this is at some expense of power; the sprocket gear, however, runs with no perceptible noise. A rheostat is placed below the car bed to control this motor, and is so arranged that any speed desired can be obtained, up to a maximum of 15 miles per hour.

One 10 h. p. motor of the regular Columbia type is used to drive each brush, one rheostat controlling both motors. The brushes are run direct from the motor with sprocket and chain. The car, as shown, is open, the motors only being covered. The covers of the two smaller ones are movable, and the large one is accessible through doors.

The car is lighted with a cluster of six lights on the trolley turret, and one on each corner of the car. This is claimed to be one of the most complete sweepers thus far constructed, and will, at a speed of from 4 to 7 miles per hour, remove snow of from 3 to 12 inches deep. In case of very deep drifts the car can be run at very slow speed and the brushes at high speed, thus cutting its way through the drift.

A special advantage of this car is the placing of the motors above the car floor, which protects them from moisture and at the same time enables the motor men to take proper care of them.

NEWBURGH, N. Y.—At a meeting of the board of directors of the Edison Electric Illuminating Company, Mr. Charles J. Lawson was elected a director, in place of the late Mr. John P. Andrews, and Mr. Jas. T. Lawson was elected vice-president of the company, in the place of the same lamented gentleman. The company decided to extend their line underground up Second from Water street to Mortgomery and north through the latter street. It was also decided to go on during the year improving the interior of the plant of the company on Montgomery street.

PACIFIC MUTUAL TELEGRAPH CO.—The directors of this company were elected Jan. 14, among them being A. B. Chandler, D. Townsend, L. D. Parker, J. A. Corby and E. C. Platt.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—XII.

(*Copyright, The Electrical Engineer.*)

BY

Herbert Laws Webb

TEST FOR CAPACITY.

The usual method of measuring the inductive capacity of a wire or cable is to compare the charge it is capable of holding with the charge held by a standard condenser of known capacity, the same battery power being used for both operations. As already explained, an insulated wire or cable constitutes a condenser by itself, the wire being one plate and the outer covering the second, with the dielectric for the separating medium.

Insulated wires and cables have a high inductive capacity as compared with overhead wires, partly because the specific inductive capacity of the materials with which they are insulated is much higher than that of air, which forms the dielectric of an overhead line, and partly because they are laid on or in the earth, as the inductive capacity of a wire increases with its proximity to the earth. The inductive capacity of an overhead wire, strung at a height of about thirty feet above the ground, is more than twenty times lower than that of a heavily-insulated underground wire having a dielectric of rubber compound or gutta percha, and more than ten times lower than that of a conductor in an underground telephone cable having a dielectric of cotton and paraffin, or cotton and resinous compound.

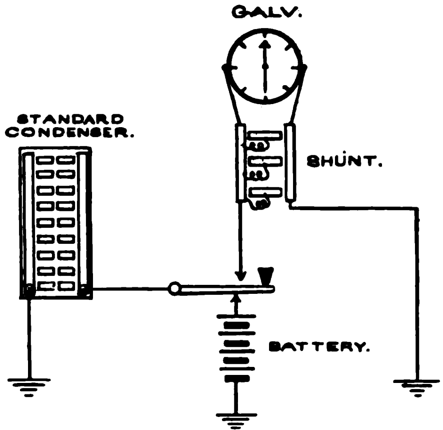


FIG. 32.

It is very important to obtain accurate measurements of the inductive capacity of conductors used for telegraphy and telephony, as this quality of the wire has a distinct bearing on its usefulness; in telephony this is more especially the case, as every hundredth of a microfarad per mile counts for a good deal in limiting the range of transmission, especially where considerable lengths of cable are used.

In Fig. 32 the connections for taking the discharge of the condenser are shown. The battery is connected to the lower contact of the discharge key, the condenser is connected to the lever of the key, and the galvanometer to the upper contact. The second pole of the battery and the other terminals of the galvanometer and condenser may either be all connected together, or put to earth. The short circuit key is held permanently open.

By pressing the lever of the discharge key down, the condenser is charged to the potential of the battery, and by letting it fly up against the upper contact, the charge is released or neutralized and flows through the galvanometer, producing a sudden throw of the needle. This deflection should be noted, as it corresponds, in a certain sense, with the galvanometer constant in the previous test.

From five to ten cells should be used in taking the discharge of the condenser, and the capacity of the condenser should be arranged (see ante, CONDENSERS) so as to have about the same value as the capacity of the wire or cable about to be measured. If the capacity of the wire to be measured is very small, such as would be the case when measuring a short length of telephone cable, or an overhead wire only a few miles long, the capacity of the condenser should be made small by connecting the sections in series, and the battery power should be increased so as to produce a large deflection. It is always best to get as large deflections as possible, as closer readings can be made and the percentage of error is less. If a long cable is to be measured the capacity of the condenser should be about one-tenth or one-hundredth that of the cable, so that the deflection given by the discharge from the cable with the $\frac{1}{9}$th or $\frac{1}{99}$th shunt in the galvanometer circuit shall be about the same as that given by the discharge from the condenser with no shunt.

THE ACTION OF THE TOEPLER-HOLTZ MACHINE.

BY

Marshall Henshaw

IN looking over the files of the ENGINEER, for 1890, a few days ago, preparatory to our annual work in electricity, I found in your issue of June 18, page 478, a communication by Mr. Willyoung criticising a little article of mine on the action of the Toepler-Holtz machine which you printed in the number of May 14, page 306.

Mr. Willyoung thinks I ought to have stated the reason why I deemed the explanation given in *Science* in 1884, and printed in leaflet by Messrs. Queen & Co., was unsatisfactory. That was not my object in writing. I had too great a respect for the author of that article, and also of the one printed in the *Electrician* the same year, to criticise a mere theoretical opinion expressed by either. I wished simply to state in a tentative way, a conclusion to which I have been led by more than ten years' experience with the machine. I referred to the other communications as not "satisfactory to some" (not *hardly* satisfactory," as Mr. W. professes to quote), as a reason for suggesting another. I shall not enter into a controversy with Mr. Willyoung. I have more important work to do.

But as he makes the very positive personal assertion that "Prof. H. could not have verified his" theory "by experiment," I beg leave to say, first, that, if the two proposed theories are "exactly the same" with slight exceptions, as Mr. W. affirms, the experiments in Queen & Co's. laboratory, as far as they have any value, bear equally against both. But, in my judgment, they are radically different. The exceptions are the essential features.

Secondly, I must say (though with diffidence in view of Mr. W.'s confident assertion) that I have tested the machine in a great variety of ways, and the results tend to confirm the theory I proposed. I have employed chiefly the *proof-plane* and two different forms of sensitive electroscopes. I have tested it with the jars on, and with them off; immediately after stopping the plate, and after it had stood a few minutes; and when the machine was in vigorous action I have stopped it, taken off the plate and carried it beyond the influence of the other parts and tested it. The armatures with the glass plate form a sort of condenser, and grounding them does not discharge them, just as grounding the outside of a charged jar does not discharge it. This is shown by the fact, that if the ground connections are removed, and the plate rotated, the machine springs instantly into full action, which it could not do if the armatures were discharged. Moreover, the *residual* charge of the jars leaves free electricity on the plate opposite the whole length of the armatures. These facts vitiate the experiments mentioned by Mr. Willyoung.

When electricity of such high potential is so rapidly produced there is an *electric field* generated all around the machine, and when the rotation ceases, there is free electricity more or less on every part. The all-important question is, What is the condition of the plate when in actions ? As it is difficult to apply tests in this case, we must rest on well established principles of electrical action. These lead me directly to the conclusions which I stated. The theory is merely a little more extended application of the generally accepted explanation of the action of Carré's Dielectric Machine.

My machine has never changed its polarity when in action, though I have charged a battery of 9 two-gallon jars so highly that they have discharged themselves across the unarmored portion.

All these theories profess to explain only the *normal* action of the machine. There are other effects which vary at times even when the conditions are apparently the same, and no one, so far as I know, has attempted to explain them.

THE THOMSON-VAN DEPOELE MINING LOCOMOTIVE.

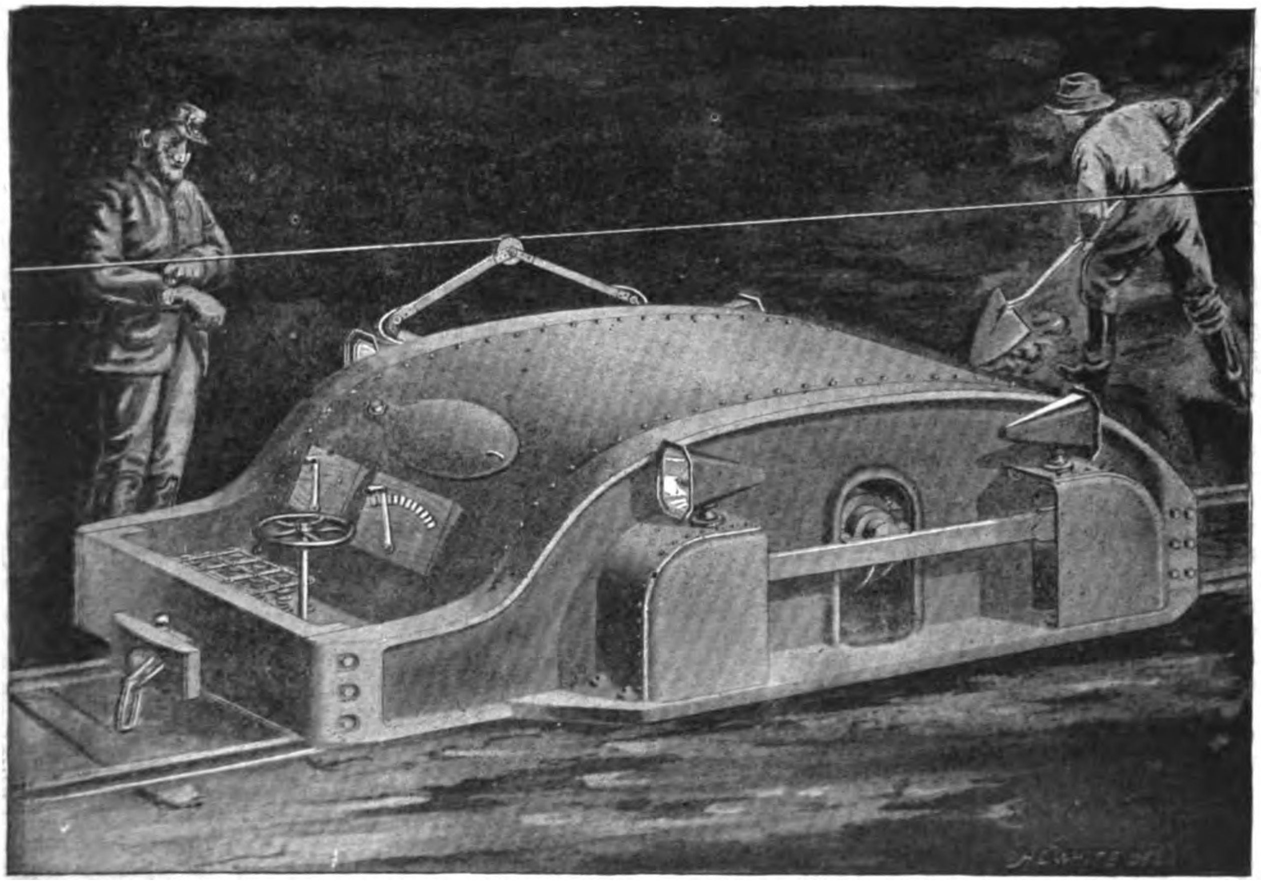
The signal success of the earlier mine haulage installation made on the Thomson-Van Depoele system has demonstrated the position which electricity is to occupy in this field of work. As an example of the most recent advance in this direction, we give in the accompanying engraving a view of the new type of Thomson-Van Depoele electric mining locomotive for underground work, which the Thomson-Van Depoele Electric Mining Company, of Boston, is now building in several sizes.

The machine shown is of 66 horse-power capacity and has a total height of 39 inches from top of rails It is built to operate on tracks of gauge varying from 36 inches to the standard 4 feet, 8½ inches.

The controlling devices are all at one end, and the body of the locomotive being so low that the view is unobstructed in either direction, the operator need not change his position in reversing the motion of the locomotive. Two electric parabolic projectors are provided at each end, making the track clearly visible for long distances.

The trolley is of the double elbow pattern, found so admirably suited to mine work in previous installations. It accommodates itself to the varying heights of the trolley-wire within any reasonable range. The sheet-iron covering makes a complete water-tight armor, protecting the moving parts from danger of falling rocks or bodies of ore and coal.

The illustration shows the locomotive in an enlarged chamber but about to enter a tunnel whose height from top of rail is scarcely four feet; hence the depression of the trolley-wire as shown.



New Thomson-Van Depoele Electric Mining Locomotive.

THE DURATION OF TELEGRAPHIC CURRENTS.

In a recent issue the *Zeitschrift für Elektrotechnik* remarks that a few figures with regard to the duration of currents used in telegraphy may be of interest. In ordinary Morse working the average duration of the signaling current may be taken at .125 second; with the Hughes apparatus currents lasting only from .04 to .05 second are emitted, while with the Meyer multiplex apparatus currents having a duration of as little as .007 second, and with the Delany multiplex of .002 second are sent to line. The lowest figure is, however, reached by the Wheatstone automatic, which, when transmitting at the rate of 600 words a minute, sends out 33,600 currents per minute, or 560 per second, each having a duration of .0018 second.

A SIMPLE METHOD OF DYNAMO DESIGN.—I.

BY

Thorburn Reid.

In the field of electrical engineering everything is so new, the laws and principles are so little systematized and so unstable, as to make rough methods almost a necessity; but that these methods are rough and wasteful, no unprejudiced person will deny. Steam engineering has been reduced almost to an exact science and no doubt electrical engineering will ultimately attain to the same degree of perfection, but many years must pass and much labor be expended by those interested, before this very desirable goal is reached.

The laws governing the flow of electricity in conductors, at least where the current is not subject to rapid variations, are now pretty thoroughly understood, thanks to Ohm's law and the laws deduced from it; but it was not till many years after Ohm's law was stated that its meaning was fully recognized by the scientific world.

We now have a similar law in another branch of electrical science, whose significance and importance are just beginning to be recognized. This law has received no name, for the reason that its statement and development have not been traced definitely to one man. It seems to have been gradually developed from vague germs of thought, till now it has reached a definite mathematical expression. This law, to put it in few words, is simply Ohm's law applied to the magnetic circuit. Rowland, in 1873, was probably the first to express it algebraically, when he wrote $Q = \frac{M}{R}$, where Q represents the number of lines of force sent through the circuit by the magneto-motive-force M, against the magnetic resistance R.

It must be remembered that this is simply a law, in accordance with which the phenomena of magnetism are produced by means of the lines of force of an electric current, or, otherwise. It is not a principle deduced *a priori* from the nature of magnetism and expressing its essential qualities, but simply an expression of what appears to be the relation between the three quantities denoted by the terms of the equation, a relation discovered and verified by experiment and apparently incapable of mathematical demonstration. It is of the nature of an hypothesis, which is used as a tool, until something better is furnished us. It is, however, a very useful tool for the purposes of the engineer and scientist, but, as in the case of most innovations, it requires time and usage before the average workman can be persuaded to use it, and the object I have set before myself in this paper is to render it more practical and better suited to the needs of the engineer by putting it in such a shape that he may use it in designing dynamos, transformers, etc., while using the units and formulæ with which he is already familiar.

The formula is unfortunately complicated by a property inherent in magnetism, which does not confront us when the law is applied to electrical phenomena, namely, that air is sensibly a conductor of lines of magnetic force, while it offers an almost infinite resistance to the passage of the electrical current; and, since all electro-magnetic apparatus must, in the nature of things, be immersed in air, an important path is offered for the passage of lines of force, whose probable effect on the distribution of the magnetism it is difficult to forecast. The amount of this disturbing element must be found out by experiment for each type of machine and allowed for by a term analogous to the factor of safety in structures built to withstand stress.

Another difficulty in applying this formula is due to the lack of uniformity in the composition and magnetic properties of the wrought iron, cast iron and steel commonly used in designing dynamos. These difficulties, however, will apply to any formula which may be used and may only be removed by numerous experiments and comparisons.

As far as I can learn, the formula promulgated by Gisbert Kapp in 1885, seems to be the one now generally used. This formula was a marked advance on the methods in vogue at that time and has been of incalculable aid to the electrical engineer. In May, of the following year, Drs. John and Edward Hopkinson reported to the Royal Society the results of investigations made with an Edison-Hopkinson dynamo, in which they made use of the formula $Q = \frac{M}{R}$, adding to some of the terms of their expression a factor, or coefficient, allowing for the leakage of the lines through the air. For some reason this formula does not seem to have received the attention it deserved from practical men, for the reason, I imagine, that their article contains many equations and long mathematical terms and phrases, and that the French units are used throughout, and the practical man, especially if he is an American, always shies at centimetres and grammes. In Thompson's "Dynamo-Electric Machinery," page 316, their method is much more simply put and its advantages pointed out.

Kapp's formula no doubt owes its popularity to his judicious choice of units and to its simple and clear form of expression, the inch, the ampere-turn and the Kapp-line (6,000 C. G. S. lines) being the units used, thus making necessary a simple division by 6,000 to reduce to volts. The one great objection to this formula is that it is not general enough. It is empirical rather than theoretical. The general formula as he stated it is $Z = \frac{P}{R_a + R_A + R_F}$ where Z is the number of Kapp-lines, P ampere-turns, and R_a, R_A and R_F the magnetic resistances respectively of the air space, armature core and field magnets. This expression is general and of the form $Q = \frac{M}{R}$. When, however, he proceeds to insert the constants for the magnetizing force and the magnetic resistances, he entirely changes the form of his equation and that is the fatal defect in it as arranged for the practical designing of dynamos. The deduction of this formula and its constants will be found in Kapp's "Transmission of Energy," page 107 (either edition), *et seq.*

Kapp first deduces the constant for the specific magnetic resistance of air as 1,880. It is really slightly greater (1,885.7). He then reduces this resistance nearly a quarter, accounting for this reduction by the presence of copper in the air space, which, he says, is more permeable than air. Unfortunately, copper is not more permeable than air, what difference there is being slightly in favor of air, and if it were not so, the difference is entirely too small to account for so large a difference in the specific magnetic resistance, even if the whole air space were filled with copper. The reason given in the first edition is even less tenable than this and was accordingly not repeated in the second. Next, for determining the constants for iron, a permeability of 940 was assumed for wrought iron and of about 600 for cast iron and the formula is said to be good up to 10 lines per square inch. Now, in most cases, the former number is too low and the latter is always too high for the ordinary cast iron used in dynamo machines. The reduction of the air space resistance will offset this discrepancy to some extent, but the relation between the two is not of the proper character to produce correct results.

Now enters our practical man and tells us that he has designed many machines by means of Kapp's formula and that, with the addition of a few constants, he has found that it gave good results and he is very well satisfied with it and does not see why he should be asked to give it up because it is not logically consistent nor mathematically correct.

My friend, your reasoning is very good, excellent, in fact;

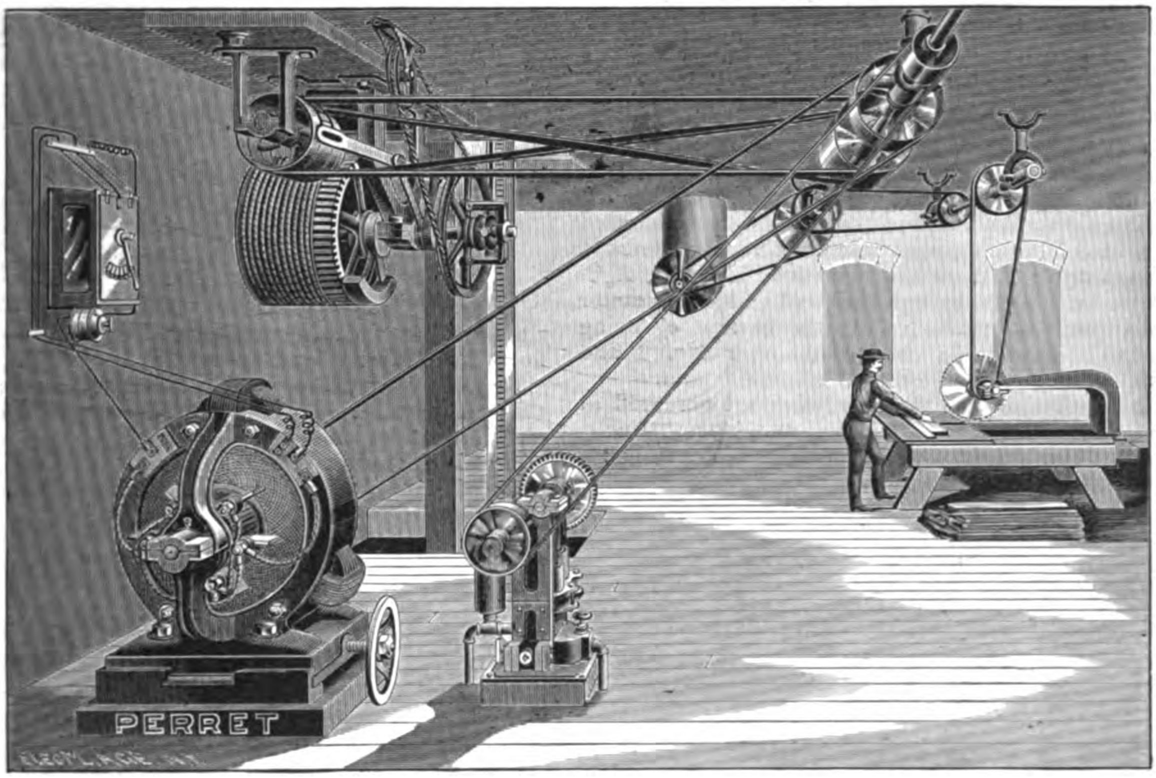
but pray, wait a moment; you have missed the point. I am not asking you to give up Kapp's formula because it is not logically consistent, but because this logical inconsistency is a radical defect in its practical working. Let me explain.

PERRET ELECTRIC MOTOR IN A WOOD WORKING ESTABLISHMENT.

The numerous advantages possessed by electric motors for supplying power in factories, is resulting in their adoption more and more extensively every year, and as a natural consequence the motors themselves are attaining, almost daily, a greater degree of perfection.

The accompanying illustration shows an interesting power plant installed in the factory of Messrs. Wm. Schwarzwaelder & Co., manufacturers of desks and office fixtures, in this city.

A 10 h. p. Perret electric motor is located in the basement, and runs a pump for raising water to the roof, a fan, a circular saw, and two elevators, only one of which is shown.



Perret Electric Motor Plant in a Woodworking Establishment.

The motor is equipped with the Perret self-feeding carbon brushes and self-oiling bearings, and is run at a speed of 600 revolutions by the current from the Edison Pearl street station. It has been in operation four months, giving entire satisfaction, and has required very little attention, the bearings being oiled but once a week, and the brushes, thus far, having been untouched. It runs without sparking and the commutator is as smooth now as when first put in.

The fact that the electric motor occupies much less space than any other class of machine of equal power is thoroughly appreciated by the users, as well as the fact that the fire risk is largely reduced, with a consequent reduction in premiums.

Jamestown, N. Y.—The Jamestown Electric Light & Power Company has elected Charles H. Tew, secretary and treasurer, vice James L. Weeks, resigned.

THE MAGNETIZATION OF IRON BY THE LEYDEN JAR DISCHARGE.

The magnetizing power of a Leyden jar discharge, although a somewhat complex quantity, depends for one thing on its duration. Thus, if a Leyden jar is successively given two equal charges, and in one case discharged very suddenly and in the other comparatively slowly, the magnetizing effect of the latter discharge will probably be greater than that of the former. This is due to the fact that the more rapid discharge produces more powerful superficial eddy currents which effectually shield the interior portions of the bar to be magnetized. The following experiment of M. A. Marianini, which was described in a recent number of the *Nuovo Cimento*, bears on this point. In the discharge circuit of a condenser M. Marianini placed an air gap and a magnetizing helix. The iron to be magnetized consisted of a glass tube filled with iron filings. He observed the deviations of a magnetometer needle, due to the presence of the iron filing cylinder, after the iron had been subjected to various discharges. The air gap was at first ½mm., and after passing ten discharges the needle only deviated by 4 deg. With a sparking distance of 3 mm., four successive discharges resulted in a magnetization strong enough to cause the needle to deviate 32° 30′. With a 7mm. gap, and after only one discharge, there was a deviation of 53° 30′. The same air gap was then used, but the resistance of the circuit was this time increased by introducing a tube containing water; deviations of 77° 30′ and 79° were then attained.

The Aransas Pass Electric Light and Power Co., of Aransas Pass, Texas, which only a few months ago started up a plant of 500 alternating current incandescent lights, has already made the experience that electric light is what the people want and that they will have it. Hence the company has also added an arc light plant to its central station. The apparatus operated is of the alternating current system of the Westinghouse Electric and Mfg. Company, of Pittsburgh, Pa.

DETERMINATION OF THE SHIFTING OF PHASE BETWEEN TWO ALTERNATING CURRENTS OF THE SAME PERIOD.

BY

Chas. Steinmetz.

THE simplest way to determine the angle of difference of phase, existing between two alternating currents of the same period, is to send one current through the movable and the other current through the fixed coil of an electrodynamometer. Then the reading of this electrodynamometer, divided by the product of the strength of both currents, gives the cosine of the angle of difference of phase between both currents.

Let the shifting of phase = angle ω.

" " strength of the respective currents = c' and c''.

Then the reading of the electrodynamometer, when one current flows through the fixed, and the other through the movable coil, is:

$$K = c'\,c''\cos\omega,$$ as is well known.

$$\text{Therefore, } \cos\omega = \frac{K}{c'\,c''}.$$

This value can be positive when angle ω is less than 90°, or less than ¼ of a period; or negative, when angle ω is larger than 90°, or greater than ¼ of a period.

Such a determination will most conveniently be carried out by the use of three electrodynamometer–ammeters.

Let the constants of these instruments = K_1^2, K_2^2, K_3^2.

The current c' is sent through the fixed coil of ammeter No. 1 and through ammeter No. 2; the current c'' being sent through the movable coil of ammeter No. 1 and through ammeter No. 3.

Then the deflections of the ammeters are observed = $\varphi_1, \varphi_2, \varphi_3$.

The current c' is determined by ammeter No. 2 to be:

$$c'^2 = K_2^2\,\varphi_2;$$

the current c'' by ammeter No. 3:

$$c''^2 = K_3^2\,\varphi_3.$$

Ammeter No. 1 reads the value of the resulting force of both currents, which is either positive, for angle $\omega < 90°$, or negative, for $\omega > 90°$.

$$c'\,c''\cos\omega = K_1^2\,\varphi_1;$$

$$\text{and therefrom, } \cos\omega = \frac{K_1^2}{K_2\,K_3}\;\frac{\varphi_1}{\sqrt{\varphi_2\,\varphi_3}}.$$

A number of applications of this method suggest themselves; for instance, for determiningt he difference of current–phase as compared with the E. M. F. Then the voltmeter or shunt current is sent through the fine wire coil of the electrodynamometer–wattmeter, this being used as a part of the additional voltmeter resistance, and the main current sent through the ammeter and the coarse coil of the wattmeter. Then the watts, read by the wattmeter, divided by the product of the amperes by the volts—the voltmeter being supposed to have no appreciable self-induction—gives again the cosine of shifting of phase.

For instance we may have the following readings:

508 watts; 36.8 amperes; 53.6 volts.

$$\text{Therefore, } \cos\omega = \frac{508}{36.8 \times 53.6} = .258;\ \text{angle } \omega = 75°.$$

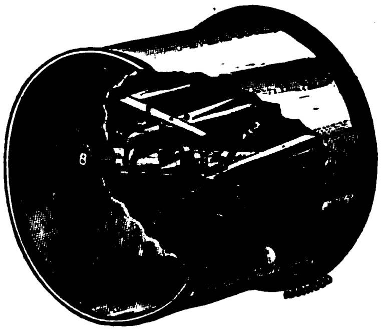
In the same way, by the use of shunt currents and electrodynamometer–voltmeters, the difference of phase between the E. M. F.'s may be measured.

NEW YORK CITY.—The Anglo-American Electric Light Manufacturing Company will hold its annual meeting in the *Times* Building on February 11th, at 2 o'clock. E. H. Sentenne is president and M. Brown, secretary.

NEW CUT-OUT FOR GAS LIGHTING BATTERIES.

GAS lighting circuits are so liable to short-circuiting that some device is necessary to protect the open circuit batteries employed for that class of work. A simple and effective cut-out designed for this purpose has recently been brought out by the Electrical Supply Co., of Syracuse, N. Y.

The cut-out which is shown in the accompanying engraving consists of three independent parts, viz.: An armature; a yoke, A, bearing a counterweight, C, and a tube which is heavier at the end, B, and is half full of a sluggish fluid. This tube may be of metal or glass, as desired. The operation will now be readily understood. When attracted, the armature pushes down the yoke, A, letting the tube tilt a trifle; the fluid begins to flow slowly toward B. After awhile the shifted weight of the flowing liquid tilts the tube and yoke still more until the tube rests against the stiff contact spring, E. The fluid then flows much faster and presently its weight forces the spring away from the insulated contact screw, D, cutting out the battery. To complete the above operation the circuit must be closed for about thirty seconds. If the circuit is cleared before that period the counter-weighted yoke will restore the tube and the fluid will flow back to its normal position. No effect is produced on the instrument by lighting the gas.



NEW GAS LIGHTING BATTERY CUT-OFF.

PLATINUM RESIDUES.

IN the face of the present high price of platinum, says the *Chemical Trade Journal*, residues and "washes" of this metal are well worth working up. The old developing baths for platinotype paper, odd bits of the paper itself, spoilt prints, etc., all may be reworked. Old developers may be treated with saturated solution of sulphate of iron—one part of the saturated solution to four parts of the developer will be about right. The mixture should be heated to boiling in a porcelain dish, and the precipitated metal collected on a filter. Bad prints, clippings, etc., of the paper should be placed on a tin or iron plate and burnt, the ashes collected and digested for some hours at 50-70° C. with *aqua regia*, and then the solution diluted with an equal volume of water, and the platinum precipitated with iron as above, or with ammonium, or formate of soda, or any other reducing agent.

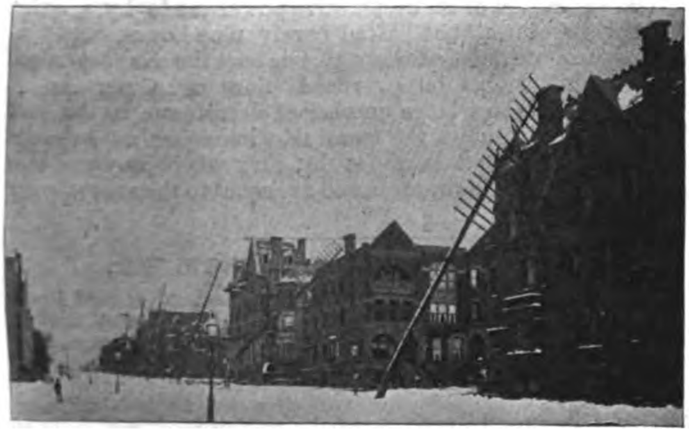
EDISON CO., OF PHILADELPHIA.—The annual report of the Edison Electric Light Company, of Philadelphia, shows that during the past year the company earned $190,000 in gross receipts. It expended $121,000. In order to increase the earning power of the company an issue of $300,000 debenture bonds was determined upon by the directors, and as a result a five-year non-interest-bearing note for $30,000 appears against the year's profits. This note was executed and delivered to the Edison General Company in lieu of royalty.

THE STORM: OVERHEAD WIRES AS A PERMANENT INVESTMENT,

BY

S.S. Wheeler.

The wet snowstorm that visited the Eastern States on the morning of January 25, left its most distinctive traces of destruction and disfigurement in this city. A few hours of heavy snow falling very quietly sufficed to do infinitely more damage to the wires in New York than was accomplished in all the long howling hours of the fierce blizzard of 1888. Last week, but for the subway work that has already been done under the supervision of the Board of Electrical Control, the electric services of all New York would have suffered utter and prolonged paralysis. As it was, the cost of repairs and renewals will run up to not less than $250,000 on a very conservative estimate; and when we emerge from the trouble and all its inconveniences, dangers and delays, the problem of putting every wire underground in this city will have made a great step towards solution.

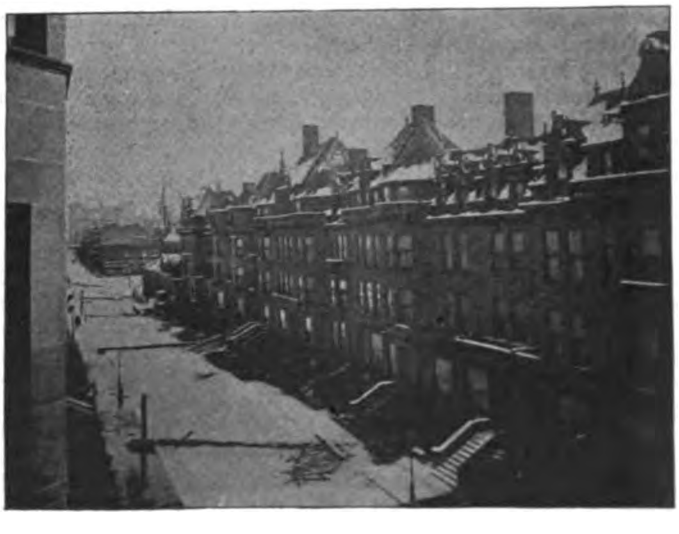


View of West End Avenue Showing Collapsed Telephone Line.
(From a photograph by Mr. E. W. Little.)

The collapse of the wires presents many curious and suggestive features. Three views, selected from a great number, are shown herewith. Some of the finest line construction in the world went by the board in an hour or two, and wonder has been expressed that such solid, substantial poles as those running through the uptown regions with telephone wires, should succumb like so much fragile "grissini." But a simple calculation will furnish the explanation. The snow as it fell and clung to the wire, fanned out beneath until each wire soon looked like a three cornered ruler slightly rounded, the wire forming the upper edge. Each foot of that wet snow weighed about one pound. If we take a pole carrying 170 wires, as many did, and allow it the strain of only 100 feet between poles, it will be seen that the extra weight thus suddenly thrown on, not allowing for the natural strain on the wire, was not less than 8½ tons per pole, applied at the height from the ground of 80 or 90 feet. Nothing but the massiveness of the poles and the excellent quality of the construction enabled them to stand as they did. When they went, however, one followed the other like the proverbial pack of cards.

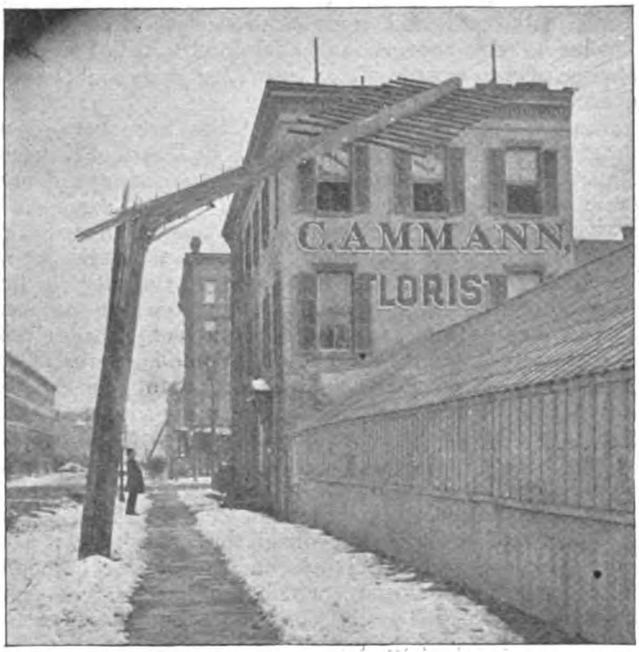
Another striking feature was the variation in the manner of break-down. I have been asked, whether, in the case of a pole line falling, the poles were usually broken or simply uprooted. Having made a special study of that point during the storm, I found that about two-thirds of the poles to succumb were broken, and that about one-third were uprooted. For the latter occurrence there is no excuse. It is easy enough to set the poles deeper. These uprooted ones were earthed only three or four feet. Many of these however were partly broken or ready to break, showing that this setting is about equal in stength to the strength of the poles. They should therefore always be set much deeper. In all the best construction now, such as the long distance telephone line, the poles are set to a depth of 8 or 9 feet, and in new soil even deeper. Evidently the uprooted poles, three feet deep in the ground, could only stand the strain of the pole itself, no allowance being made for the strain of what it had to carry. The uprooted poles represent an old and reprehensible style of construction that meets with no sanction to-day, and that not even the absence of public supervision in earlier years could warrant or excuse.

One method of construction that has been carried out under the direction and approval of the Board of Electrical Control, pending the completion of all the subways planned, came through the terrible ordeal most successfully. Hitherto it has been the practice to place the electric light wires bottom of all, although they are the strongest and least liable to break. On First avenue, the electric light circuits of the Manhattan Company have been put away up above everything, at a height of 80 feet. These circuits consist of 40 single cables, containing one heavy conductor each. The cross arms are braced with stout iron brackets and the poles are carefully cross-guyed with each other. The guys start about 8 feet from the base of the one pole and are secured at about the same distance down from the top of the next, so as to take the strain from the pole at about the same point as that at which it is applied, and thus prevent bending. The insulators are placed well out from the poles to clear the guys, and to leave a "man hole" between the wires through which the lineman can easily and safely get at his work. That pole line stood without a scratch. None of the circuits came down. Below them the storm played havoc with the telephone and telegraph wires crossing at right angle; but they merely dropped to the street without the risk of short circuiting any electric light current. It may be added that, as a general thing, the electric light circuits all over the city had very little damage inflicted on them by the storm directly, and the work on them consisted entirely of clearing them of debris, whose presence required that they should remain inoperative until quite free. The slowest to get clear has been that on Seventh avenue, where a wholesale sweep was made by the falling telephone line between Fifty-eighth and Thirty-fourth streets.



A Prostrate Telephone Pole Line in West Seventy-Third Street, N. Y.
(From a photograph by Mr. E. W. Little.)

The collapse of the telephone line just referred to is rather interesting. It started at a pole up which went a subway terminal pipe. The guy stop across the street had been cut away by the Bureau of Incumbrances, and consequently, when this extra weight came on it, over went the pole, there being nothing to counterbalance it, and it and all its fellows fell in succession, raking south. Had that pole also been cross guyed it would have stood. Another telephone line without guys was that on Park avenue, where the poles fell to the east, and in orienting themselves the whole length of the avenue from 59th to 125th streets, smashed the iron railings around the open spaces of the steam railroad beneath.



Broken Telephone Pole, West 120th Street, N. Y.
From a photograph by Inspector F. E. Brown, of the Board of Electrical Control.)

The Metropolitan Telephone Company, upon whom the heaviest blow fell—3,897 subscribers being disconnected—are more than confirmed by the storm in their intention to get every wire underground as quickly as possible. Even where the incompleteness of the subway system might allow them to rebuild, they will not attempt it, feeling that the permanence of the old overhead system is not great enough. Thus, the Fourth avenue line, now down from Fifty-ninth to Harlem, they will abandon entirely. On Thirty-ninth street from Sixth to Eleventh avenue they will also abandon the entire line. Part of this, from Sixth to Eighth avenue, is replaced by a subway just about ready for occupation, and they will go into that. From Eighth to Eleventh avenue, where there will in all probability be overhead lines for some years to come, they will try to go on the housetops if possible. If not, they will ask permission to put up small, light poles, similar to the electric light poles ; and in any event, instead of stringing individual wires, they will put up cables each carrying 50 or 100 wires, and distribute by means of cable boxes. These cables are not likely to collect snow and ice, and if they fall will do so only a short distance and will not make a tangle of wire. In other words, the plan means the applying of subway methods to overhead construction until in due time the subway is ready, when the same cables can be readily transferred to it if sound.

The somewhat celebrated West End Avenue (Long Distance) line will not be replaced, but instead of spoiling a fine residential district, the same circuits will be taken through Sixty-sixth street to Tenth avenue—a region of gas works—and thence run out. This magnificent line will be well remembered by those members of the National Telephone Exchange Association who inspected it from the tops of stages at the invitation of the Telephone Co., during the convention in this city two years ago. The wires of the Thirty-eighth street Exchange, which suffered very severely owing to the preponderance of overhead lines in its network, will be at once connected up with the terminals of the new subway work, and thus its service will very soon be largely an underground one.

The loss of the local and long distance telephone companies is enormous, and connot be put at less than $150,000 to $200,000, a heavy loss for even rich corporations. The telegraph companies came off pretty well, though beyond the city limits they felt the full brunt of the storm. I am informed that the Western Union had as many as 1,600 poles down between Jersey City and Wilmington, Del. In our Annexed District, the Postal Telegraph Co. had a whole pole line wiped out. The fire and police services were both sorely crippled, and even now can hardly be said to have recovered their full efficiency.

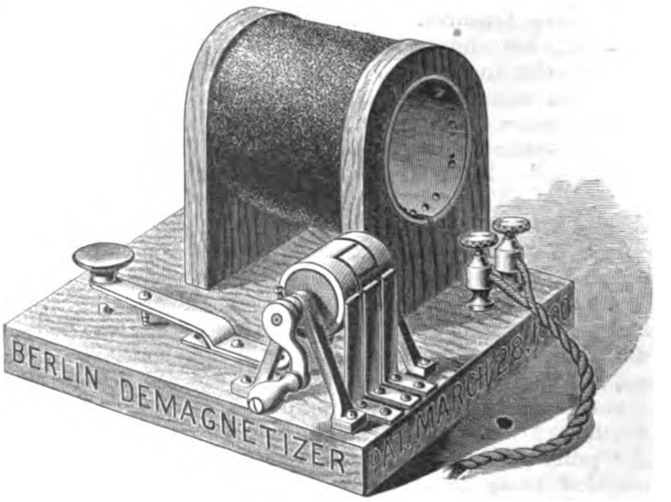
The exhibition of its destructive power made by a quiet little snow storm that lasted barely nine hours, ought to suggest in interested quarters throughout the country some weighty reflections on overhead lines as a permanent investment where a large number of circuits are to be run together, and to point the moral that imperfect as subway systems and methods may yet be, they alone answer the requirements of the situation and are equal to the emergency in a great city.

A SIMPLE WATCH DEMAGNETIZER.

The general adoption of electricity to the comforts and luxuries of life, in the home, the workshop, on the street cars, and in fact everywhere, while bringing its manifold advantages and blessings, at the same time creates a condition of things relative to our watches which did not heretofore exist.

Wherever a dynamo machine is in operation, there is more or less stray magnetism, and a watch happening in this vicinity is quite liable to become magnetized, being thereby rendered worthless as a time-piece until deprived of its magnetism. Consequently, any contrivance which will make it a simple matter to demagnetize a watch will be considered useful to all central station and electric railway men, and if such a device were placed in each station or power house, a large "demagnetizing business" would soon develop.

The accompanying engraving shows the Berlin "Demagnetizer," a simple machine devised for this purpose. The instrument can be used with either a constant or an alternating current circuit. If only the former current is at hand, the small crank attached to a pole changing commutator is revolved, thus causing the current passing through the coil to become alternating, with the consequent effect of neutralizing any magnetic body passing through it. Of course, if connected to an alternating circuit, the pole-reversing attachment need not be used.



The "Berlin" Watch Demagnetizer.

The watch is passed through the centre of the coil, then removed very slowly, being kept in a straight line with the centre, until entirely removed from the magnetic field. The constantly decreasing field of alternating polarity acting on the watch, deprives it of all magnetism. The instrument is manufactured by the Berlin Demagnetizing Co. of this city.

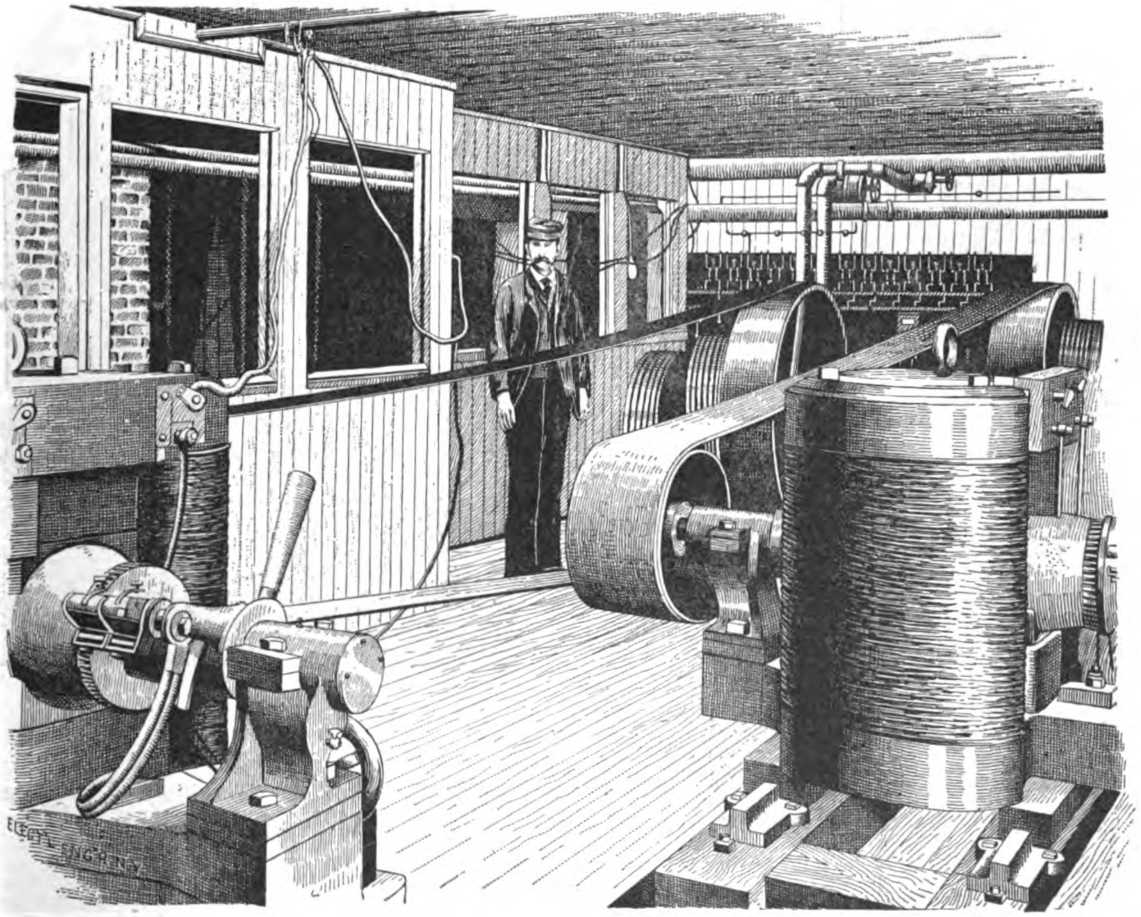
THE LOOMIS PLANT, MANHATTAN AND MERCHANTS' BANK BUILDING, N. Y.

BY

McSullivan.

It is a rare exception at the present time to find an office building erected that does not include, among its appointments, an electric light plant. These installations, with their high-class machinery and novel details, rarely fail to be of interest.

A model plant of this kind has lately been installed in the Manhattan and Merchants' Bank building, 40 and 42 Wall street, this city, by the Eureka Electric Co. It consists of two 400-light Loomis compound-wound automatic dynamos. The winding of these dynamos is such that it does not matter whether the whole number of lamps are in circuit or not, the potential remaining constant; and this is quite a valuable feature in an office building, where the lamps are turned on and off indiscriminately, thus varying the load, and should the dynamo be unable to take care of itself it would require constant attention. Consequently, the life of the lamps is materially increased.



Loomis Incandescent Plant, Manhattan and Merchants' Building, N. Y. City.

The dynamos are driven by two Beck engines of 60 h. p. each, connected to the dynamos by double leather belts.

The building is wired for 1,000 lights, the Grimshaw White Core being used throughout. A separate feeder is run from the dynamo room in the basement to each of the ten floors, and are connected on the switch-board to the bus bars by double pole jaw switches.

A separate feeder is run to each of the two banks, and also halls and lavatories.

The switch-board is made of marbleized slate and presents a neat appearance with its brass and copper fittings. It is so arranged that the plant can be divided in two, one dynamo taking half the number of lamps and running them independently; or, by throwing in a plug switch, the bar is made continuous and both machines are thrown into multiple arc. A ground detector is placed on the switchboard, so that should a ground come on the system it will be noticed at once.

The current is carried from the dynamo to the switchboard through copper bars, and each dynamo connects to it from opposite sides.

The entire plant is a most complete one, and shows thorough knowledge on the part of those who had it in charge, of the best methods of construction now in vogue.

THE JAMAICA AND BROOKLYN (L. I.) RAILROAD.

The State Railroad Commission—William E. Rogers, chairman, Isaac V. Baker, Jr., and Michael Rickard—have given a hearing to the application of the Jamaica and Brooklyn Railroad for permission to use electricity as a motive power. The road has been running its cars by the trolley system of overhead wires for two years and desires to continue to do so. The authorities of Brooklyn and Jamaica brought suit against the railroad some time ago to have certain local restrictions imposed. Edward S. Clinch, who appeared as counsel for the company, informed the Commissioners that his client was willing to submit to any reasonable local restrictions.

Representatives of Jamaica and Mr. Clinch agreed:

'That the Jamaica authorities should regulate the rate of speed, the posts should be presentable, the cars should be managed by not less than two men, the induction of electricity from the overhead wires to adjacent wires should be prevented, there should be a protective wire above the road electric wires, and that the company should conform to such reasonable regulations as the local authorities might impose."

THE UNIVERSAL THEATRICAL ARC LAMP.

THE use of the calcium light on the stage is always attended with considerable inconvenience, the cylinders, and pipes necessary for its operation being cumbersome, and the noise and heat annoying. These difficulties are successfully overcome by the use of the theatrical arc lamp, shown in the accompanying engravings, and made by the Universal Arc Lamp Co., of this city.

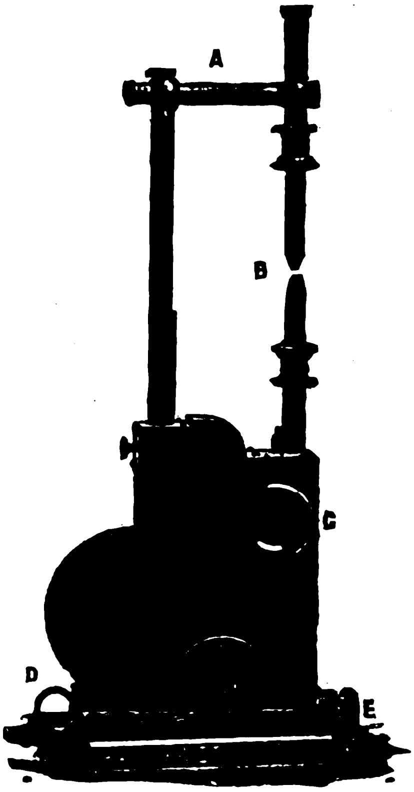


FIG. 1.—THE UNIVERSAL THEATRICAL ARC LAMP.

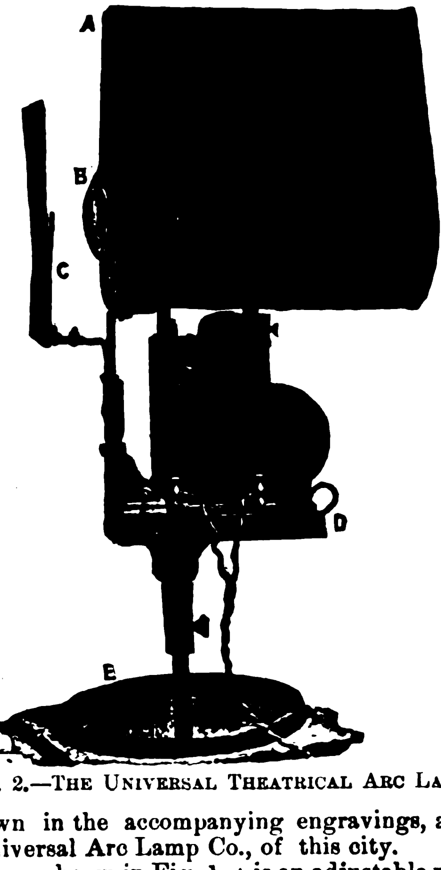

FIG. 2.—THE UNIVERSAL THEATRICAL ARC LAMP.

In the lamp shown in Fig. 1, A is an adjustable rod to hold the upper carbon. C is the feeding screw and D, the handle for adjusting the focus. By means of the handwheel E, the adjustment of the relative carbon feed is effected. The intensity of the light can be varied from 100 to 10,000 c. p., and the lamp, operating at only 45 volts, is perfectly safe to handle.

Fig. 2 shows the lamp mounted on a stand and resting on the iron cradle D. A and B show the lens box and lens, respectively, and C, a small color holder.

In Fig. 3, A is a small reflector and C the plug for connecting the lamp with the resistance box by means of the socket, D; J being the stand adjustment screw.

To avoid the possibility of making a wrong connection, the plug and socket, C and D, are made V-shape.

Besides doing the work of the calcium light, this lamp can be used in producing many novel and striking effects, such as the natural rainbow, illuminated fountain, morning clouds, thunder-clouds, chain lightning, and others.

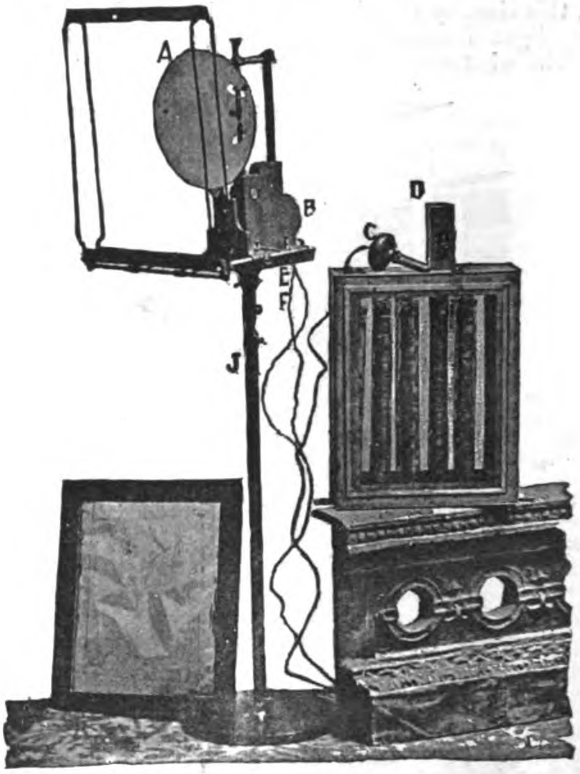

FIG. 3.—THE UNIVERSAL THEATRICAL ARC LAMP.

MR. JAMES ENGLISH has taken up the controversy on municipal lighting at New Haven, Conn., and, in the newspapers there, has brought forward a variety of figures going to show how incomplete and inaccurate are the statistics which have been published to show that municipal lighting is cheaper for a community than that which it pays for under contract with a private corporation. The cause of this controversy is an address made by Mayor Sargent before the Trades Council favoring municipal ownership.

MUNICIPAL ELECTRIC LIGHTING.—In calling attention to a bill introduced in the Pennsylvania Legislature allowing municipalities to go into the business of electric lighting, the *Oil City Derrick* says it intends to offer a strenuous objection to the passage of general legislation of this sort. It says that as a result of such indiscriminate venturing upon business enterprises, the bonds of Ohio municipalities are a cheap and over abundant article, and the average Ohio town and city is head over heels in debt. Moreover, city operation of electric plants has not yet been demonstrated to be a success, and "judging from experience of muncipal control in other lines, it never will be."

MR. DAVID BROOKS has offered to the city of Philadelphia the free use of his underground system, with which, he claims, a 3-inch pipe carrying 500 conductors can be laid at a cost of $1600 per mile.

NEW THOMSON-HOUSTON SINGLE REDUCTION CAR GEAR.[1]

FOR about a year past it has been an open secret that the Thomson-Houston Electric Co. were experimenting with a new slow speed motor for street railway service, but not till the present, after long and severe tests, have they felt justified in putting it upon the market. This new machine has been named the S. R. G. motor.

The photographs from which our engravings were produced we obtained on a recent visit to Boston and Lynn where we had the privilege of inspecting the S. R. G. motor, studying the details of its manufacture, and also of a ride on a West End car (No. 120) equipped with two of these machines. The operation of the gear is practically noiseless, and the tests show that the motor is more powerful in driving the car than the double reduction high speed motors with the same current.

As will be noted from the illustration, Fig. 1, the motor is nearly iron clad, having two internal pole pieces of ample spread, carrying two field coils which partially surround the armature core, on the same principle as the well-known arc light dynamo originated by Professor Thomson. The magnetic circuit is completed on the front end of the motor by the nose plate, and on the back end by the frame, on which are cast the axle boxes and arms, which serve as a support for the armature shaft bearings, Fig. 2. The armature is of the Gramme ring type, and the bobbins are wound close together around the entire rim, Fig. 3; one great advantage of this construction is the fact that any coil can be easily rewound without disturbing its fellows, while with the drum armature in the type of motor formerly used by the company and still largely used, the winding all had to be renewed down to the injured coil.

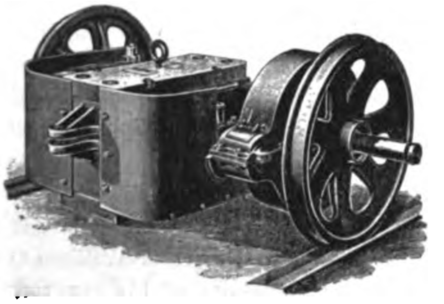

FIG. 4.

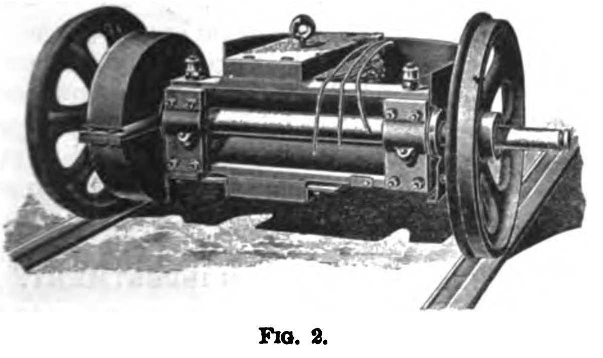

FIG. 2.

The brushes are placed exactly opposite and in a horizontal, fixed position and are easy of access.

The field coils are protected on all sides by the fields and frame. The gears are entirely enclosed in a dust and oil-tight case, which is provided with a handhole closed by a spring cover, Fig. 4, permitting ready examination of gears and the introduction of lubricants. A sheet iron pan, Figs. 2 and 4, extending above the centre of the armature shaft entirely encloses the bottom and sides of the motor and protects the armature and commutator from dust, snow and water. The advantage of this casing was strikingly demonstrated during the recent snow storms, the S. R. G. coming through unscathed while some of the fields on the old style of motor came to grief from the effects of excessive moisture. This pan has a sliding bottom and is attached to the motor in such a manner as to permit of being readily removed for access to the various parts.

The motor when mounted on a truck with thirty-inch wheels is designed to clear the top of the rails four inches, Fig. 5. The spur pinion on the armature shaft is of steel, four and a half inches face, and has fourteen teeth, The split gear which is bolted on the car axle is of cast iron with the same width of face, and has sixty-seven teeth. The speed of the armature shaft relative to that of the car axle is nearly 4.8 to 1, and when the car is running ten miles per hour the armature makes 538 revolutions per minute, or the speed of the armature is 53.8 turns per minute per one mile per hour.

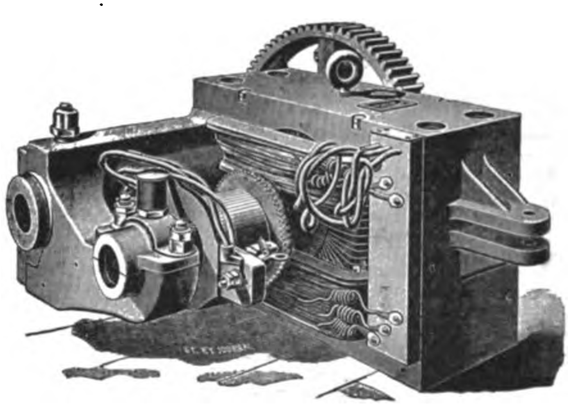

FIG. 1.

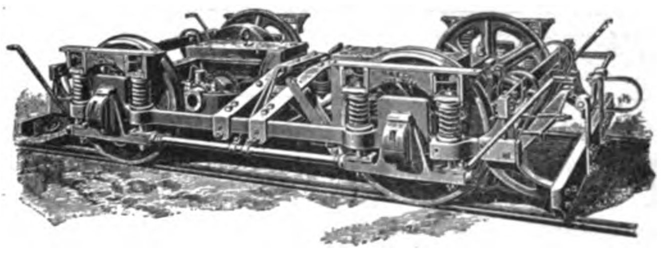

FIG. 5.

The facility with which the armature can be removed simply by lifting the upper field, the ease with which an armature bobbin can be rewound, less liability to damage from centrifugal action, such as bursting of binding wires displacement of coils, breaking of commutator connections, all insure a minimum amount for repairs.

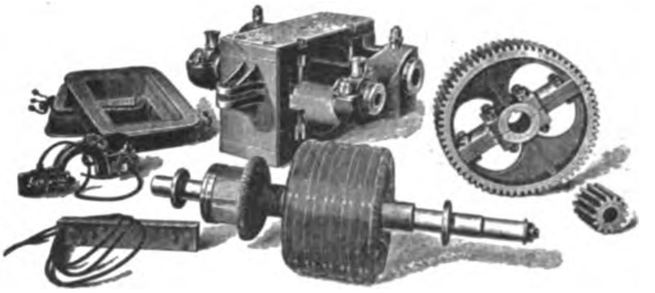

FIG. 3.

The only perceptible sound is the rolling of the car wheels on the rails. The grating of the gears and fretting of the commutator bars against the brushes, so offensive with the old type of motor at high speed, is eliminated.

The new machine having practically an iron clad magnetic field, avoids the liability to short circuit, common to motors supported by a nose plate.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XI. NEW YORK, FEBRUARY 4, 1891. No. 144

The inventor to secure his success, must consult the discoverer, and the practical skill of one be directed by the theoretical knowledge of the other.—Joseph Henry.

A CENTURY OF THE AMERICAN PATENT SYSTEM.

IT is proposed, and all the preliminary arrangements have now been completed for the purpose, to celebrate next April in Washington the completion of the first century of the American patent system. In connection with the meeting then held, it is also intended to organize a National Association of Inventors. Both ideas are excellent, and the programme issued privately in advance indicates that the greatest interest is taken in the matter by influential and representative men. Not only will the special sessions be presided over by President Harrison, Secretary Noble and Prof. Langley, but the papers to be read at the regular meetings will be the production of distinguished judges, economists, statisticians, publicists and engineers, and will deal with every phase of the patent system ~~and~~ its effect upon society.

Such an occasion as this will be a most favorable one for impressing upon the public mind the enormous benefits that the system has conferred upon American civilization and development. Strange as it may seem, there are not a few opponents of our present liberal patent law, and not a few who are so ignorant of its principles as to characterize the ownership of a valuable patent as a "gigantic monopoly." If we wish to stop the present rapid rate of advance in the arts and sciences, in general welfare and individual comfort, all that is necessary is to abandon the system; and the convention will do a great service if it have no other result than enlightening the public as to the manner in which our patent laws, while rewarding the successful inventor, confer incalculable benefits at the same time upon society at large. The system is not perfect—far from it—but it is one of the most useful and praiseworthy of our institutions, unsurpassed as a creator of property and values, and of blessings common to all.

One reform the convention should insist on, and that is that the Patent Office shall at least be decently housed. In our columns this week will be found a letter from a well-known public man, who, visiting the Office only a few days ago, was horrified and disgusted with the conditions of things there. Yet it has even been contemplated to make matters worse by more crowding and by filling up the interior court with another building, so that the supply of light and air already so inadequate will be still further reduced. The convention must make a firm demand, admitting of no refusal, that a part of the large surplus now to the credit of the Patent Office shall be spent in the extension of its facilities, either in its old home or in a new one. And while it is about it, and is putting a hand to practical reforms, the convention might as well ask that the staff of the Office shall be paid higher salaries, more commensurate with the quality and quantity of the work done.

CROOKES ON RADIANT MATTER.

SOME twenty years ago Professor William Crookes first gave to the world the results of his experiments on the state of matter in high vacua. The scientific world was dazzled, and justly so, by their brilliancy and by the power of the reasoning brought forward to explain their action. Radiant matter has since then remained the subject of discussion from time to time, but thus far the hopes, at one time expressed, of the practical utilization of the phenomena involved have not been realized. In his inaugural address before the London Institution of Electrical Engineers, Prof. Crookes rapidly reviews these phenomena and adds a few new ones to those already known, accompanied by a discussion in the light of his most recent researches. These cannot fail to call attention again prominently to what we believe must eventually lead to results of the highest practical importance. True, it would be difficult to point out in the present state of our knowledge the exact path to pursue in obtaining these practical results, but the problem of obtaining light without heat is now one of such immediate moment and the pecuniary reward consequent upon a successful solution of the problem is so great, that the energies of inventors can be bent in no more hopeful direction than this.

OVERHEAD WIRES AS AN INVESTMENT.

THE late snowstorm with its wholesale destruction of pole lines throughout this city had many lessons, and in the very interesting article by Dr. S. S. Wheeler, the Subway Board's expert, they will be found in brief summing up and explanation. In order to give an exact idea of the damage inflicted on adjoining houses, we have made two or three reproductions from photographs kindly furnished us. It is evident, however, both from the article and the illustrations that in an episode of this kind the companies suffer rather than the public. To read the daily papers, one would think that the snapping of a single wire meant death to thousands of citizens; but here we have the breakdown of thousands of wires and hundreds of poles without a single fatality. Dr. Wheeler hits the nail on the head in the title to his article, suggesting that as a matter of finance and management, overhead wires are too costly to be looked upon as a permanent investment, if they are thus to be blown out of existence or broken down by snow every other year. It will be gathered from what he says that subway work will be appreciably expedited by the late storm, and that such overhead construction as remains will be much improved. It is one cause of satisfaction that the maligned electric light circuits were those least affected by the storm, and that where better methods of construction had been resorted to, their behavior left nothing to be desired.

THOMSON-HOUSTON SINGLE-REDUCTION CAR GEAR.

We have on more than one occasion referred to the fact that the present tendency in electric railway work leans towards the reduction of the number of gears employed in transmitting the power from the armature shaft to the car axle. We have also described quite a number of devices designed, for this purpose. It is significant, therefore, to note the undoubted influence which the new idea is obtaining in the methods of work of one of the largest companies in the field. The new departure by the Thomson-Houston Company, illustrated this week in our columns, will, without doubt, have considerable influence on the future methods employed and is another evidence of the progressive nature of electric railroading. The high-speed electric motor on the electric car has done, and is doing, excellent service, and the change to the present style is not to be looked upon in any way as a setback to the high-speed motor *per se*, but rather as a recognition of the fact that every additional link in power transmission necessarily involves a loss in power as well as other inconveniences which it is desirable to avoid as far as possible.

THE WORK OF THOMAS DAVENPORT.

When Moses went up from the weary plains of Moab to the top of Pisgah and viewed afar the promised land as it lay below with green valleys and well watered pastures and waving palm trees, he was but the type of the leaders in many another and later field of work. They have been the pioneers; they have borne the burden and heat of the day; they have grown old and wornout in devotion to duty; and then, when the end is reached to which their efforts alone have conducted, they do not enter in.

There may, after all, be some compensation in this, as in most cheatings of hope, and part of this compensation doubtless lies in the fact that it saves from even greater disappointment than is actually endured; while the fact remains, clear to admiring posterity, that whatever was possible at the time was accomplished. Herein is the victory, and not in the mere handling and enjoying of materialities that would of themselves be but poor stimulus or solace to the aspiring spirit of high purpose or lofty genius.

As we read, therefore, the last page of Mr. Pope's fascinating chapters on the work of the Vermont blacksmith, we realize, though Davenport did not, that he had then traveled as far as could be gone along the road of discovery that in later years has brought us to the grand utilization of electricty as a motive power. The modern motor existed in his mind and was roughly shaped by his hands, and he died with the belief that in carrying out his ideas to the full he would have settled the whole problem. But dissolving zinc would never stand the competition of burning coal, and hence, failing a better source of current than the primary battery, Davenport would have been doomed to even sharper disappointment than was in reality his lot. It is curious to note how with that remarkable instinct of the intellect which knows what is lying beyond the difficulties, he said that any idea of limitation in the size of an electric motor affected him with "peculiar disagreeableness." To-day, with huge dynamos as a central source of current, he could build his motor any size he wished, and none would say him nay.

Mr. Pope is entitled to very hearty thanks and praise for the pains and skill with which he has written this life of a truly noble man and paid a richly deserved tribute to the first American inventor of the electric motor.

THE "HENRY."

In the early days of modern dynamo construction much of the work, if not all, was accomplished by the application of empirical rules and it was not until the true theory of the dynamo and of the relation of the magnetic and electric circuits was brought out that dynamo designing may be said to have been reduced to a science. The alternating current dynamo, and alternating apparatus generally, have passed and are passing through much the same change, but in the latter a factor, present in the continuous current apparatus to a perceptible degree, springs at once into the greatest prominence, namely, self-induction, and must be considered accordingly. The basis of the calculation of alternating current apparatus must, therefore, be referred to some unit. Such a unit was adopted by the Paris congress and termed the "quadrant." A short while ago Prof. F. B. Crocker very properly suggested the propriety of naming this unit the "henry," and mainly through his labors in connection with the Committee of the American Institute of Electrical Engineers appointed for that purpose, the henry has now been adopted as the practical unit of self-induction and has already secured a firm place in electrical literature. The discussion on this unit which took place at a recent meeting of the Institute, would seem, on the surface, to lead to the opinion that the various definitions of which the unit is susceptible might lead to considerable uncertainty in practice; but we cannot doubt that, as time passes and a better insight is gained by a large majority of working electricians into the true nature of the unit, this apparent disparity will disappear. If, as one of the speakers pointed out, the conditions under which each experiment is effected be known, there ought to be no difficulty in reducing the results to a common basis of comparison. The adoption by the Institute of the henry as the practical unit will, we are certain, give the unit a firm standing among engineers. This is already evidenced by the fact that the Society of Civil Engineers has adopted it, which action, without doubt, will be followed by other societies throughout the country, and we hope, abroad.

ELECTRICITY IN TRANSITU: FROM PLENUM TO VACUUM.[1]

BY WILLIAM CROOKES, F. R. S.

IN submitting to you certain researches in which electricity is used as a tool, or as a means of bringing within scope of our senses phenomena that otherwise would be unrevealed, I must for a moment recall to your minds the now generally accepted theory of the constitution of matter.

KINETIC THEORY OF GASES.

Matter, at its ultimate degree of extension, is conjectured to be not continuous, but granular. With speculations as to the constitution of liquid and solid matter I need not trouble you, but will proceed at once to the third or gaseous state of matter.

The kinetic theory of gases teaches that the constituent molecules dart in every possible direction with great but continually varying velocities, coming almost ceaselessly in mutual collision with each other. The distance each molecule traverses without hitting another molecule is known as its *free path*; the average distance traversed without collision by the whole number of molecules of a gas at any given pressure and temperature is called the *mean free path.*

When the mean free path becomes comparable to the dimensions of the containing vessel, the attributes which constitute gaseity shrink to a minimum, the matter attains the ultra-gaseous or "radiant" state, and we arrive at a condition where molecular motions under electrical impulse can easily be studied.

The mean free path of the molecules of a gas increases so rapidly with progressive exhaustion, that whilst that of the molecules of air at the ordinary pressure is only $\frac{1}{10000}$th of a millimetre, at an exhaustion of a hundred-millionth of an atmosphere—a point (which, with present appliances, is easy to attain) corresponding to the rarefaction of the air 90 miles above the earth's surface—the mean free path will be about 30ft.; whilst at 200 miles above the earth it will be 10,000,000 miles, and millions of miles out in the depths of space it will become practically infinite. I could go on speculating in spite of Aristotle, who said: "Beyond the universe there are neither space, nor vacuum, nor time."

In discussing the motions of molecules we have to distinguish the *free* path from the *mean free path.* Nothing is yet known of the *absolute* length of the free path nor of the *absolute* velocity of a molecule. For anything we can prove to the contrary, these values may vary almost from zero to infinity. We can deal only with the *mean* free path and the *mean* velocity.

THE VACUUM PUMP.

As most of the experiments I put before you to-night are connected with high vacua, it is not out of place to refer to the pump by means of which these tubes are exhausted. Much has been said lately in recommendation of the Geissler pump and its many improvements, but I am still strongly in favor of the Sprengel, as with it I have obtained greater exhaustion than with any other. I should like to point out that the action does not stop when we cease to see air specks passing down the tubes, but continues long after this point has been passed. Neither is the non-conducting vacuum, so easily obtained by the Sprengel pump, due in any way to the presence of mercury vapor, since non-conduction can be obtained just as rapidly when special precautions have been taken to keep mercury vapor out of the tubes. One of the great advantages of the Sprengel pump over all others lies in the fact that its internal capacity need not exceed a few cubic centimetres, and there is, therefore, much less wall surface for gases to condense upon.

THE PASSAGE OF ELECTRICITY THROUGH RAREFIED GAS.

The various phenomena presented when an induction spark is made to pass through a gas at different degrees of exhaustion point to a modified condition of the matter at the highest exhaustions. Here are three exactly similar bulbs, the electrodes being aluminum balls, and the internal pressures being respectively 75 mm., 2 mm,, and 0.1 mm. If I pass the induction current in succession through the bulbs, you will perceive in each case very different luminous phenomena. Here is a slightly exhausted tube, Fig. 1, like the first in the series just exhibited (75 mm.), the induction spark passes from one end to the other, A B, and the luminous discharge is seen as a line of light, acting as a flexible conductor. Under the tube I have an electromagnet, C, and on making contact the line of light dips in the centre down to the poles of the magnet, and then rising again proceeds in a straight line. On reversing the current the line of light curves upwards. Notice that the action of the magnet in this case is only local.

In a highly exhausted tube the action is quite otherwise. Such a tube is before you, Fig. 2, and in it I have carried the exhaustion to a high point (0.1 mm.). I pass the induction current and you perceive the electrified molecules, like the line of light in the first tube, also move in straight lines, and make their path apparent by impinging on a phosphorescent screen, D E. If, however, I submit them to the action of a magnet, C, their behavior is different. The line dips down to F, but does *not* recover itself.

It seems that in the tube first shown we have to do with the average behavior of the molecules of gas in its totality. In the second case, where the gas has been greatly attenuated, we are merely concerned with the behavior of the individual molecules of which it it was originally composed.

THE STRATIFIED DISCHARGE.

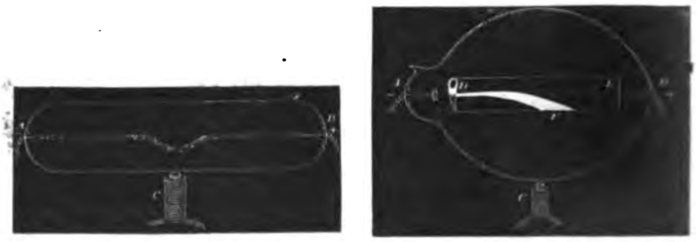
When the gas is rarer than is necessary to give the flexible line of light, as shown in the first experiment, the luminosity is plainly discontinuous, or, as it is termed, stratified.

Suppose we experiment on little particles of some substance, such as sand, approximately equal in size. If we mix the particles with water in a horizontal tube and set them in rhythmical agitation, we shall see the powder sorting itself with regularity into alternate heaps and blank spaces.

If we pass to yet more minute substances we observe the behavior of the molecules of a rarefied gas, when submitted to an induction current. The molecules here are free, of course, from any caprice, and simply follow the law I seek to illustrate, and though originally in a state of rampant disorder, yet under the influence of the electric rhythm they arrange themselves into well-defined groups or stratifications; the luminosities show where arrested motion with concomitant friction occurs, and the dark intervals indicate where the molecules travel with comparatively few collisions.

PARTI-COLORED STRATIFICATIONS.

As another illustration of stratifications in a moderately exhausted tube (P. = 2 mm.), I will take the case of hydrogen prepared from zinc and sulphuric acid after being passed through various purifying agents, dried in the usual manner, and exhausted with a mercury pump, Fig. 3. I pass the induction current, and we see that the stratifications are tri-colored, blue, pink, and grey. Next the negative pole, A, is a luminous layer, then comes a dark interval or Faraday's dark space (see below), and after this are the stratifications, the front component (*b*) of each group blue, the next (*c*) pink, and the third (*d*) grey. The blue discs are somewhat erratic. At a certain stage of exhaustion all the blue components of the stratifications suddenly migrate to the front, forming one bright blue disc, and leaving the pink and grey components by themselves. The tube before you, Fig. 4, is at this particular stage of exhaustion, and on passing the current you observe the blue disc only (*b*) is in front. When the tube contains a compound gaseous residue of this kind, the form of stratifications can be very considerably altered by varying the potential of the discharge. This alteration in the forms of stratification was first pointed out by Gassiot (1865, "B. A. Abstracts," p. 15), who gave very full descriptions and drawings of the alterations produced by putting in resistances of various lengths of distilled water. The alteration depends simply upon the difference of potential.



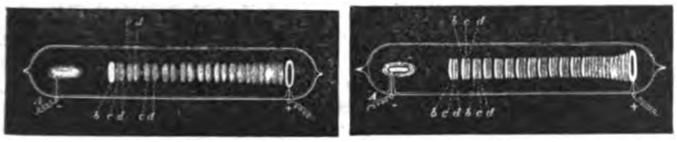
FIGS. 1 AND 2.

THE DARK SPACE.

After the stratification stage is passed we come to a very curious phenomenon, the so-called "dark space." Studying electrical phenomena in gases, in the year 1838, Faraday pointed out a break in the continuity of the luminous discharge separating the glow of the positive electrode from that of the negative. This he called "the dark space." It is seen in tubes containing gas only slightly rarefied, as in this tube, Fig. 5 (P.=6 mm.), where you will observe that the positive glow, extending as a pink streak from the positive electrode, B, ends about 10 millimetres before the spot of blue light, C, representing the negative glow. This gap, or non-luminous hiatus, D, is Faraday's "dark space." Separating the negative glow from its electrode is another space. In this tube it is so small that the glow appears to be in actual contact with the electrode, but on exhausting a little further it rapidly separates; and in the next tube, Fig. 6, containing air at a little less pressure (P.=8 mm.), this dark space, E, has extended so as to remove the negative glow about four millimetres from the electrode, A. It is with this second dark space that I particularly wish to deal to-night. Therefore I shall refer to it as the "dark space," meaning always that in the negative glow.

---

[1] Abstract of presidential address delivered before the London Institution of Electrical Engineers.

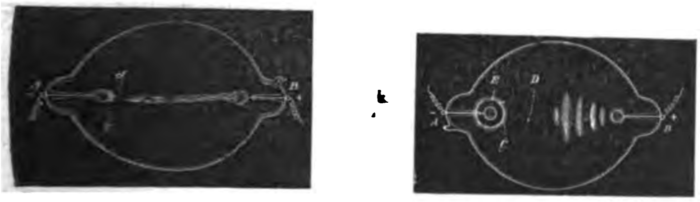


FIGS. 3 AND 4.

In the experiment just shown with hydrogen stratifications the contents of the tube under the electric discharge still obey the laws following from the average properties of an immense number of molecules moving in every direction with velocities of all conceivable magnitudes. But if I continue exhausting, the dark space, E, round the negative pole, A, becomes visible, grows larger and larger, and at last fills up the entire tube. The molecules at this stage are in a condition different from those in a less highly exhausted tube. At low exhaustions they behave as gas in the ordinary sense of the term, but at these high exhaustions, under electric stress, they have become exalted to an *ultra-gaseous* state, in which very decided properties, hitherto masked, come into play.

The radius of the dark space varies with the degree of exhaustion, with the kind of gas in which it has been produced, with *the temperature* of the negative pole, and to a less extent with *the intensity* of the spark.

It has been erroneously assumed that I ever said the thickness of the "dark space" represents the mean free path of the molecules in their ordinary condition, and it has been pointed out that the radius of the dark space is decidedly greater than the calculated mean free path of the molecules. I have taken accurate measurements of the radius of the dark space at different pressures, and compared it with the calculated mean free path of the gaseous molecules at corresponding pressures when not under the influence of electrical energy, and I find that they do not bear a constant relation one to the other. The length of the dark space is not 20 times the mean free pass, as some have estimated, but a gradually increasing multiple must be taken as the exhaustion becomes greater.



FIGS. 5 AND 6.

(*To be Continued.*)

Society and Club Notes.

THE WINTER MEETING OF THE MAGNETIC CLUB.

At Martinelli's, on January 28th, the Magnetic Club held its Winter meeting, beginning with the usual dinner. The new president, Mr. Edward C. Cockey, was in the chair, and the guests of the evening were Mr. A. B. Chandler and Mr. George G. Ward. A very happy little speech was made by Mr. Cockey in acknowledgment of the honor recently conferred upon him, and he expressed his intention of making the meetings more useful and enjoyable than ever. He then introduced Mr. Chandler, who read a brief paper embodying his reminiscences as an operator at Washington, in the War Department, during the the Civil War, when he was brought into frequent and intimate contact with President Lincoln, and enjoyed not a few confidences of that great man during some of the most exciting episodes of the conflict. The paper was heard with breathless attention and at its close, on motion of Mr. C. P. Bruch, who is the son of an old military telegrapher, it was resolved that the paper should be printed by the Club, with the permission and revision of its author. Mr. George G. Ward followed in a very amusing and stimulating extemporaneous address in which he traced his career briefly from the time when he began as an operator at the mature age of seven years, and only two years afterwards was called upon to instruct a stupid ticket and freight agent fifty years old, on one of the English railroads. When, by the reluctant consent of his father, a railway official, he at last entered the telegraphic profession in regular course, he was sent to Egypt and performed his duty through a tremendous epidemic of cholera in Alexandria. Soon after this he became connected with submarine cable work, and thus has been brought to his present high position in connection with the Commercial Cable Company.

Remarks were also made during the evening by Messrs. W. J. Dealy, George H. Usher, "Senator" Ives and K. E. Brannin, while numerous recitations were given by Messrs. J. W. Kelly, E. E. Delaney and H. L. Nicholls, and song and piano recitals by Messrs. B. J. Knittle, F. Krummling, A. F. Hurd, D. W. McAneeny and C. Van Baar.

PROVIDENCE MEETING OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

To commemorate in a proper manner the completion of the first decade of the commercial use of electricity for the services of light and power, the National Electric Light Association invites all persons interested in electrical work or undertakings to join with it on the occasion of its Thirteenth Convention to be held in Providence, R. I., February 17, 18 and 19, in celebrating the close of the first decade of electric lighting, and in honoring the pioneers of electrical industries.

The following persons, representatives of the principal departments of electrical developments, have been invited to participate in the celebration, as the guests of the Association: Telegraphy, Dr. Norvin Green; Ocean Telegraphy, Cyrus W. Field; Telephoning, Alexander Graham Bell; Arc Lighting, Chas. A. Brush; Incandescent Lighting, Thos. A. Edison; Electric Street Railroad, Hon. Henry M. Whitney; Electric Welding, Prof. Elihu Thomson; Technical Education in Electrical Engineering, Gen. Francis A. Walker; Steam Engineering for Dynamo Driving, Gardiner C. Sims; Organization of the National Electric Light Association, Geo. W. Worthington.

The Association also invites all pioneer workers in electrical undertaking to participate in this celebration by their presence and by contributing for publication over their signatures an account of some interesting episode in their early experiences with electrical work. The morning session of the convention, on Wednesday, the 18th, will be designated "Memorial Session." and will be devoted exclusively to the recitation of such remembrances. All contributions will be published in the Volume of Proceedings after the convention, and will thus form a memorial of the beginnings of the electrical industries.

Appointments, Etc.

MR. SIMEON F. ELLIS has been appointed superintendent of the electric railroad at Quincy, Mass.

MR. B. J. WEEKS has been appointed superintendent of the Boston and Quincy electric railroad, with headquarters at Boston.

CHIEF THOMPSON, of the fire department, of Richmond, Va., has been appointed to take charge of the wiring in the new city hall in that place.

MR. THOMAS C. PERKINS, has been appointed electrical expert to superintend the installation of electric light wires at Bloomfield, Conn.

MR. CHARLES H. SPEAR has been appointed superintendent of street lights of Lynn, Mass.

MR. JACOB H. JACOBY has been appointed superintendent of telegraph on the Lehigh Valley railroad, Mr. J. W. [illegible] having resigned.

MR. J. J. RYAN has been appointed city electrician of San Antonio, Texas.

MR. W. L. BONNELL has been reappointed superintendent of the Norwalk and South Norwalk Electric Light Company, of South Norwalk, Conn.

THE TELEPHONE IN NEW YORK CITY.

The Metropolitan Telephone Co. has begun a crusade against the "Whisperphone" attachment to the transmitter. An interesting exposé has also been made of the plausible and peculiar schemes of the Telephone Subscribers' Association, one or two officers of which have been trying to render subscribers discontented at a charge of $5 per head for doing so.

INDUCTANCE AND ITS PROPOSED UNIT, THE "HENRY."

As noted in our last issue, a discussion of Mr. A. E. Kennelly's paper on the above subject, and also of the committee's report on the proper value of the Henry, took place at the 53rd meeting of the American Institute of Electrical Engineers, on Jan. 20th.

PROF. FRANCIS B. CROCKER read the report of the committee[1] and referred to the desirability of writing the plural of henry as "henrys." He considered it hardly necessary to settle upon any particular method of defining the unit because each one would choose whichever seems best.

DR. CARY T. HUTCHINSON remarked that if by the practical unit is meant the unit corresponding to the ohm, and which is an even multiple of the C. G. S. unit, then it would have one value. If, however, by the "practical unit" one meant that value which will fit the ordinary equation of induction, of which Ohm's law is only a special case, the unit would have another value. In other words, the unit of current in the electro-magnetic system is defined absolutely; the legal ohm, or whatever unit of resistance is chosen, is arbitrarily defined, and its relation to the ohm is determined experimentally. He thought the definition in terms of the centimetre was unfortunate, for the reason that its dimension, being a length, was purely artificial, and was so only on account of the "suppressed dimension." The definition should be in terms of the phenomenon; that is, the counter-electromotive force, expressed in terms to suit the C. G. S. "practical" or "legal" unit, as may be decided.

The speaker also objected to the adoption of the unit on the ground that the Institute lacked jurisdiction.

MR. TOWNSEND WOLCOTT, referring to the passage in Mr. Kennelly's paper, "It may be well to notice that inductance is only conventionally and perhaps not essentially a length," and to the remarkable quoted statements of Prof. Rücker on this point, called attention to the fact that they showed the amount of misapprehension which exists among scientific men regarding so simple a subject as the theory of the dimensions of physical units. Inductance was not a length; there was no room for a doubt regarding that question. To be sure, the *unit* of inductance had the dimensions of the *unit* of length in the electro-magnetic system of units, but then in the electro-static system it had the dimensions $L\ T$.

If inductance really were a length, not only ought we to be able to measure it by some of the methods of measuring length, but it would be absurd to encumber our nomenclature with a new name for an old unit. We should by all means stick to quadrant, or centimetre as the case might be. After what had been said it seemed almost unnecessary to remark that no discovery in science can change the dimensions of magnetic permeability, or of any other unit in either of the present systems of units. We might discover a better system of units, but that is all.

It had been shown that electric current had always the same dimensions as magnetic potential. There are two other quantities related in the same manner, namely, quantity of magnetism and electro-kinetic momentum of a circuit, m and p, have the dimensions in the two systems $[L^{1\cdot 2}\ M^{1\cdot 2}]$ and $[L^{3\cdot 2}\ M^{1\cdot 2}\ T^{1}]$. We may, therefore, substitute m for p in any equation without altering either the dimensions or the numerical value of the other quantities. It is on this principle that Sumpner and Fleming's definition of inductance is founded. Maxwell defines inductance as the ratio between the electro-kinetic momentum of a circuit and the current, that is, $\frac{p}{C}$. Sumpner and Fleming say, the ratio between the total induction (the same as Maxwell's quantity of magnetism), and the current. This is simply substituting m for p in the ratio giving $\frac{m}{C}$ = inductance. On the same principle we may substitute for the current the magnetic potential at a point where the solid angle is numerically equal to the reciprocal of the permeability when the ratio becomes $\frac{m}{\Omega}$, the quantity of magnetism divided by the magnetic potential, the analogue of the quantity of electricity divided by the electric potential or electro-static capacity. Electro-static capacity has the dimensions of a length in the electro-static system and of the reciprocal of an acceleration in the electro-magnetic system, just the reverse of inductance. The speaker expressed himself in favor of the quadrant value for the henry.

MR. GEO. A. HAMILTON referred to the fact that probably more was done, and at an earlier date, in the way of measuring self-induction than would be inferred from Mr. Kennelly's remark concerning the history of the same. Certainly as early as 1883, and he believed earlier, it was common practice with those in the telegraph service, to measure the *extra current* of the different forms of duplex and quadruplex relays that were brought out. He believed also, similar measurements were made in the British post-office service. Tests of this kind by himself were made by comparing the "kick" of the instruments under similar conditions in a balanced bridge, and also by shunting them with condensers of known capacity, and observing the reduced "kick." Regarding the name for the unit, he was decidedly in favor of the "henry," with "s" for the plural. He inclined also to 10^9 for its magnitude for the reasons given in the paper. He believed it would be found convenient in practice, and the micro-henry could take care of the small values.

MR. THORBURN REID believed that the committee ought to define clearly what the henry is to be the unit of. It was ordinarily called the unit of self-induction, but the term "self-induction" includes more and less than the quantity which is to be expressed in henrys. It is a general term connecting all the phenomena due to the creation of lines of force in a coil through which a variable current is flowing. Thus we have the E. M. F. due to self-induction, the lag due to self-induction, the work due to self-induction, the coefficient of self-induction, etc., any one of which the henry might be the unit of, and of only one of them it is the unit, namely, the coefficient of self-induction. All things considered, it appeared best to call the henry "The Unit of Inductance," a term suggested, he believed, by Fleming and used by Mr. Kennelly in his paper. In the next place it would be well to define exactly what this term "inductance" means. Fleming, using the ordinary term L to denote inductance, has defined it in three ways by means of the following equations:

$$L_1 = \frac{e}{\frac{d\,i}{d\,t}} \ (1) \qquad L_2 = \frac{N}{i} \ (2) \quad L_3 = \frac{2\,T}{i^2} \ (3)$$

In equation (1) e is the E. M. F. of self-induction. $\frac{d\,i}{d\,t}$ is the time rate of change of the current. In (2) N is the total induction through the coil, and in (3) T is the energy of self-induction. The second of these equations is inconsistent with the other two and is manifestly wrong. Thus the first of the three equations gives L as the ratio of the E. M. F. of self-induction to the time rate of change of the current; in other words, the E. M. F. of self-induction equals L times the time rate of change of current. He suggested that the committee define inductance according to the first and third of the definitions given above.

There was another consideration in favor of adopting as the unit of inductance 10^9 absolute unit, which he had not heard mentioned, and that was the fact that, in equations involving inductance along with other electrical quantities, we may perform directly all the algebraical operations without having to enlarge the value of L. There was another consideration bearing on this subject; the effect it was hard to predict at the present time. That is, the variation in the value of the permeability of iron and steel. This variation will cause the values of the henrys obtained by means of the first and third of the three equations to be different. Taking L as the ratio of the electromotive force of self-induction to the time rate of change of the current, we would get for a 10-light Westinghouse transformer and assuming a permeability of 800, nine henrys; this calculation would give .14 ampere as the current passing through the converter on open circuit, which is very nearly the actual current in practice. Taking the third definition, half of the magnetic energy of self-induction divided by the current, we get in this particular transformer something less than one henry. Exactly what that means he had not been able to make out as yet.

PROF. F. B. CROCKER, Chairman of Committee, said that in regard to the unit of inductance being a question of length, he did not suppose that there was any question that these dimensions are arbitrary to a great extent, and differ with each system, but the committee had adopted the electro-magnetic system; and we never use the electro-static system, and are not likely to use it. Therefore it does give certain importance to the dimensions of the unit, being always expressed in terms of that system and are always likely to be. Furthermore the language of the report, which, he presumed, brought forth this criticism, simply states that 10 to the 9th power absolute units of induction, shall express a length equal to one earth's quadrant, which is certainly a fact, and it was given more to show why it was called a quadrant; in other words, to cover the subject as far as possible. But however arbitrary the diminsions of the units, they are not absolute, but will change with the system, and as we were not likely to change the system, therefore, the diminsions are not likely to change.

As to the question of definition, he thought that was a very important matter. In regard to the criticism as to how the value of the unit will be affected by the variations in the value of the ohm or volt, that would take care of itself. Ultimately, he presumed, the volt will be the correct volt, and the ohm will be the correct ohm, and in that case the unit of self-induction will be the correct unit.

In regard to the importance of the unit of inductance, and the whole matter of self-induction, he believed that it would be used nearly as much as resistance, and that the unit of inductance would, in the future, have perhaps very nearly as many uses as the ohm. For example, in all alternate current work; in the telephone, and in the armatures of even the continuous current machines, the self-induction was as important, or more important, than the resistance. Therefore, this unit was destined to very extensive use, perhaps equal to that of any other electrical unit, with the exception, possibly, of the volt and ampere.

---

[1] See THE ELECTRICAL ENGINEER, January 28, 1891.

The question of exactly what the unit applies to—what the conception should be aside from its value—a definition of that he thought was also very important. The coefficient of self-induction of course is the ordinary idea; but that is defined in terms of a unit change of current in a unit time. Now, as a matter of fact, supposing we have ten units' change of current in a unit time, then we have ten times the self-induction; the coefficient will be no greater, though. If we have a certain electro-magnet and we discharge it, we take out ten amperes of current, and cause ten amperes of current to cease flowing in one second. The actual self induction would be that due to the change of current, ten amperes in one second. The coefficient of self-induction would be calculated from a change of current of one unit in one second. Therefore, one might say that we have the coefficient of self-induction and the actual self-induction in any given case. It is perfectly possible that one might have a variation of a tenth of an ampere in a second, but the coefficient of self-induction would be that due to the unit change of current in a unit time. He thought that the distinction between the coefficient, which is a special case due to a unit change, or a unit variation of current in a unit time, was one thing, and the actual self-induction in any given case, which may be ten units of change or a tenth of a unit, was another thing. That was usually more important than the coefficient of self-induction, because that was what we actually got. The actual self-induction was very much more important than the coefficient of self-induction.

Mr. A. E. **Kennelly** remarked that as regards the apparent discrepancy between the dimensional values not only of inductance, but of every other quantity in electricity and magnetism as stated in the electro-static system or in the electro-magnetic system, the fact that there is a discrepancy shows the imperfection of our knowledge of the subject, because if we did possess more accurate knowledge, there could be one and only one true expression of length, mass and time, which would denote the quantity we study. Now it is a very important matter to know whether inductance can be truly expressed as a length or not. The common opinion is that it must be so, and it usually is so expressed. It can not in all probability be a length, because, as has been pointed out by several speakers, it is capable of being expressed in the electro-static system as the inverse of an acceleration. The whole subject, therefore, required some future revision, but when our knowledge becomes more perfect as we all expect it will be concerning the nature of these phenomena, so, proportionately, will our definitions be more clear, and there will be one, and only one definite expression of inductance considered in terms of length, mass and time.

As regards the right or the grace of the Institute in dealing with the question of what the name of the unit should be, perhaps, as had been pointed out, the lead in the matter should be taken by more strictly scientific bodies representing the country. But in this case, as in many others, it is the practical men who point out the requirements, and as a body of practical engineers, the Institute had a perfect right to set forth its necessities, to create provisionally, perhaps it may be, a practical unit for them, and to recommend the name of that unit to the next International Electrical Congress.

A very important matter was the question of how the unit shall be defined. If we had no iron it would be very simple, because all these three definitions of induction would all be one and the same thing in terms. But unfortunately in dealing with iron, we come across a difficulty. He differed with Prof. Crocker that to back electromotive force was the one which conveyed most clearly and most effectually the nature of inductance. When he saw a coil he could imagine the number of linkages with that coil, and more readily estimate in this way its inductance than he could by forming a conception of its counter electromotive force with change of current. That was, however, only a matter of opinion; but there was this advantage, that the method of referring inductance to the number of lines linked with a coil is one which is very fundamental and simple. It does not require any recourse to the differential calculus, as the others do, because the time rate of change has to be defined as the instantaneous time rate and not the time rate in any actual period elapsed.

The only hope, as it appeared to him, is to specify that inductance shall be expressed by any of those three definitions, and then to say that the inductance with iron has to be referred to the inductance that would exist without the iron by the use either of the specified conditions of the test, or of the specified conditions of the iron.

Mr. C. O. Mailloux thought that the remarks of Prof. Crocker in reference to expressing inductance in terms of counter E. M. F., constituted a suggestion of some importance. In practice with alternating currents, we do not deal with the instantaneous values of current or E. M. F. but we make our calculations on the basis of mean effective or average values corresponding to a given cycle or period of the electrical action. Inductance has been defined as the product of a length by a permeability, with the assumption that the permeability is unity. Now we might express the inductance as the product of two factors, one of which is a coefficient simply whether we regard it as representing *length* or anything else (we might, if we prefer, call it a *length* factor or coefficient); the other factor being what might be termed the "mean effective permeability." Since the permeability undergoes a series of variations when the current rises from zero to the upper limit or maximum value reached in the given cycle, we have a series of values to consider. If we multiply this mean value by the length factor we have the mean effective value of the inductance. What we usually get, when we measure inductance is in reality the product of those two factors. Unfortunately we do not have the means of separating them, unless we regard the length coefficient as the inductance value that would be obtained if the iron were removed from the magnetic circuit; and regard the other factor (the mean effective permeability) as the factor indicating how many times the inductance is increased when the iron is present. The principal thing needed was a value for the inductance which can be treated as if it were constant for a whole cycle, or a whole period, and which will reconcile theoretical ideas with practical requirements. He saw no difficulty in this way of approachihg the question.

Prof. Crocker replying to Dr. Hutchinson said he thought it would be a great mistake to define the henry in terms of legal volts and ohms or whatever may be involved in the definition at the present time, making it necessary to change that dimension at some future date.

Mr. Charles Steinmetz remarked that when one took into consideration the fact that this term inductance will be used mainly for explaining and calculating the phenomena of alternating currents, then the suggestions that Mr. Mailloux made—the introduction of this "effective value" of inductance—he supposed would be found more useful than even the true analytical term, inductance. He did not consider the choice of the name "effective" as a happy one, because that suggests something of the nature of a square-root of a mean square, and this value, which Mr. Mallioux meant was not the square-root of the mean square of the different values of inductance during the magnetic cycle, but was, in reality, very nearly the inductance for that value, which corresponds to the maximum magnetization used, and therefore he would prefer another name, which is not so liable to be misunderstood, for instance, "resulting inductance." He had had occasion to make over a thousand determinations of the value of self-induction, and of the work consumed by hysteresis, over a very large range, up to values where the hysteretic loss amounted to more than a thousand watts, and he always found the value of inductance very near the value previously calculated for the maximum magnetization of the cycle.

Mr. Kennelly thought it safe to say that the concensus of opinion at the present time among the members, was in favor of adopting 10^9 centimetres as the practical unit, the henry to be spelled in the plural "henrys," and that there was no difficulty in defining it in a copper coil which has no iron in it or near it, because it may be defined with equal truth in any one of three ways, those three ways giving the same result at all times, and for all currents. That so soon as iron is introduced, the inductance would probably vary with the way in which the measurement is made, the time during which the current is changing, and the value of the current, and the only way out of the difficulty from a general standpoint, was to define inductance as though there were no such thing as iron, and then to say that when we are measuring any inductance which is iron-clad, to specify the current used, and the way that it is obtained, so as to arrive at the permeability of the iron at that moment and its rate of change.

Letters to the Editor.

THE CONDITION OF THE PATENT OFFICE.

Cannot something be done to arouse the attention of Congress to the inadequate provision for the transaction of business at the Patent Office, and the care and safety of the valuable archives? I was there a few days ago, for the first time in many years, and was surprised and annoyed to see that notwithstanding the great growth of the business, but little more space is available for the use of officials and employees than they had at command thirty or forty years ago. The important work of the examiners is performed under the most unfavorable conditions. Although the rooms allotted to them are but of moderate size, it seemed to be the rule to crowd from ten to fifteen people in one room. Of course it is impossible but that there should be a large accummulation of papers, considerable confusion, and consequent loss of time. The rooms occupied by women were even worse crowded. To say nothing about health conditions, it is impossible that the public business can be properly conducted under such circumstances. Then, consider the disastrous consequences of a fire which should make headway in the building. Patented inventions enter into our great industries as never before in any other land. How important it is that the record of protected inventions should be preserved unimpaired!

While I was in Washington, the entire time of Congress was taken up with the consideration of such subjects as the Force Bill, Cloture, &c., matters which were destined to come to naught. And I could not help thinking, as I saw the neglected condition of the Patent Office, how much to be desired it is that Congress should call a halt as to its abortive discussions of partisan schemes, and bestow a little attention upon the material interests which are suffering sorely for the want of that consideration which of right should be extended to them. And I contrasted the reprehensible squandering of the public money on fraudulent pensions and on venal pension agents with the niggardly treatment of the Patent Office, and other departments equally demanding the attention of the public servants. It is too bad that there should be such a misappropriation of time and money. And I fervently hope that in some way the attention of Congress to this meritorious subject may be compelled. H. H.

PROVIDENCE, R. I., Jan. 30, 1891.

Reports of Companies.

STANDARD UNDERGROUND CABLE CO.

The annual meeting of the Standard Underground Cable Company was held January 27, at the company's office in the Westinghouse Building. It was well attended by the stockholders, there being nearly 9,000 shares of stock represented. Mr. George Westinghouse, Jr., was elected president; and the following were elected directors: George Westinghouse, Jr., Mark W. Watson, John H. Dalzell, Robert Pitcairn, Joseph W. Marsh, James H. Willock, and H. S. Sweitzer.

The annual report of the board of directors was exceedingly gratifying to the stockholders. It showed that the company's business for the year 1890 amounted to $917,646.62, representing an increase of 50 per cent. over the business done in the year 1889. The net earnings for the year 1890 were $204,913.78, or a little over 20 per cent. on the entire capital stock; two dividends aggregating $30,000.00 were paid during the year, leaving the net addition to surplus account $174,913.78. The company's net surplus on December 31st, 1890, was $315,735.85.

The raw materials used by the company during the year were as follows: 342.549 pounds of cotton and jute yarn, 1,625,209 pounds of copper, 1,853,538 pounds of lead.

During the year 1890, the company added 84 new customers to its already large list, and its business covers a wide range of territory, as is graphically illustrated by the large map of the United States shown in the company's office, nearly every state and territory of which is dotted with circles or crosses indicating the cities in which the company's underground cable and overhead wire, respectively, are in use; and the markings on Johnson's Commercial Chart of the World show that the company's business is not limited to the United States, but extends to Mexico, South America, Europe, Africa, Asia, China and Japan.

STOCKS AND BONDS.

HOLLEY, N. Y.—The Holley Electric Co. shows capital stock of $7,500.00, all of which is paid in. The debts of the company are $65.23 and a surplus of $475.90 over all liabilities is reported.

KALAMAZOO, MICH. The City Electric Company, of Kalamazoo, Mich., has increased its capital to $60,000.

HARLAN, IOWA, has voted to extend the city limits and bond for water works and electric light.

LYNN, MASS.—The stockholders of the Lynn & Boston Railroad Company have voted to petition the Railroad Commissioners for authority to increase the capital stock by an amount not exceeding $500,000 for expenses to be incurred in adopting electricity as a motive power.

RUTLAND, VT.—In accordance with a vote of the stockholders of the Rutland Electric Light Company, the capital stock of the company has been increased from $50,000 to $100,000. It is divided into 5,000 shares of $20 each.

DIVIDENDS.

FALL RIVER, R. I.—The Edison Electric Illuminating Company, of Fall River, has declared a quarterly dividend of 2 per cent.

ELECTIONS.

NEW YORK CITY.—At the annual meeting of the American Range-Finder Company the following officers were elected: President, Edward A. Wickes; secretary and treasurer, D. W. McWilliams; directors, Edward A. Wickes, A. J. Forbes-Leith, D. W. McWilliams, S. D Schuyler, and Richard Irvin, Jr. It was stated in the course of the meeting that the Russian government had already purchased one of the Fiske range-finders and that they are now undergoing trials by other foreign governments with a view to their introduction into the navies of those countries.

"Electrical Bohemia."—M. E. E. & M. A.

THE members of the Boston Electric Club listened to a very entertaining and instructive paper at the Club rooms this week, by Mr. F. M. Gilley, associate editor of *Electrical Enterprise*, a new electrical journal which is springing into prominence amongst the electrical papers published in Boston. The subject of the paper was "Electrical Bohemia," a name, however, which did not at all prepare one for the interesting lecture which followed. Mr. Gilley described in some detail, and in a somewhat humorous manner, a recent trip made by himself to England and France, and gave many interesting details of electrical progress, or rather want of progress, in these countries. The various central electric light stations in London and Paris, the underground electric railway in London, and the system of underground conduits in Paris were all briefly described, and special mention was made of the extensive house lighting by electricity in London. The subject was described in an able, racy and comprehensive manner, and spoke volumes for Mr. Gilley's powers of observation of the methods of our friends on the other side. At the close, a few remarks were made relative to the topic under discussion, and a unanimous vote of thanks was passed to Mr. Gilley for his successful effort to interest, please and entertain the members of the club. *Electrical Enterprise*, the journal above referred to, was started at the beginning of this year, and has now reached its fourth number. The staff of the paper consists of Mr. John G. Lynch, editor; Mr. Frank M. Gilley, associate editor, and Mr. Albert P. Bicknell, manager and publisher. Now that the young paper has got a footing on the threshold, I desire to extend it a welcome as a contemporary, and trust that the same good work which has appeared in the first four numbers may be continued, and wish them a hearty success. The tone of the paper, though not technical, is newsy and the editorials are bright and clever, and deal in an enterprising way with the electrical topics of the day.

The Massachusetts Electrical Engineers and Mechanics' Association gave their first annual ball in Odd Fellows' Hall, on Thursday evening, the 29th inst. Naturally, the members, being largely composed of electrical men, turned their attention to the special decoration of the ball room, and succeeded in producing a dazzling effect. Mr. N. Olsen, chief decorator, had charge of the arrangement, and used just exactly 497 incandescent lamps. The words "Welcome, M. E. E & M. A." were formed of a number of lights over the platform, while suspended from the centre of the hall was a representation of Ben Franklin's famous kite, also composed of electric lights. From the centre to numerous points on the way, stretched long streamers of bunting with lamps at intervals, of various hues, and all round the room lamps were distributed in lavish display. A switchboard had been provided with 22 circuits by which all sorts of marvellous effects could be had by the blending of the different colors on the various circuits. All the lamps, apparatus, current and wire were loaned by the Edison Illuminating Company, while the work itself was done by members in spare moments. The reception committee was headed by Mr. John Dean, Jr., the committee on order by Mr. S. F. Lawton, and the corps of floor directors by Mr. Frank O. Johnson. To the efforts of the affable president of the Association, Mr. James E. Cole, the generally agreeable results of the affair were greatly due. A most enjoyable evening was spent, and a very comfortable sum of money was realized, which will be spent in procuring a suitable library for the Association.

BOSTON, Jan. 31, 1891.

Obituary.

MR. N. E. SWARTWOUT.

Nelson E. Swartwout, who committed suicide at New Orleans recently, was formerly a resident of Chicago, and was at one time a well-known electrician. For eight years prior to 1884 he was private secretary to Professor Elisha Gray, of Highland Park, through whom he became widely known. In 1884 he was made secretary of the old Sectional Underground Conduit Company, which office he held until Professor Gray gave up the management of the affairs of the company in 1887. Since that time Mr. Swartwout had served in several positions, among them the managership of a large hotel at St. Paul. He leaves a wife and daughter in this city.

TELEPHONE vs. ELECTRIC RAILWAY.

Two suits for damages have been filed by the Cumberland Telephone Company against the United Electric Railway Company, of Nashville, Tenn., one for $5,000 and the other for $7,000. The actions are based on alleged damage to the complainant's wires by the defendant.

FIRST ANNUAL REPORT OF THE ELECTRIC MUTUAL INSURANCE COMPANY, OF BOSTON, MASS.[1]

The causes which induced the formation of this company were the following:

The exorbitant rates and exacting conditions imposed by "stock companies"—the difficulty, even of procuring necessary reliable insurance in those companies on electrical risks, together with the vacillating action in the matter of rates, which are subject to the whims and prejudices of local boards and compacts; and also the realization that the enormous capital invested in electrical industries requiring insurance called for a company of its own. The unfairness of the stock companies' rates (notwithstanding their protestations to the contrary) can have no more potent demonstration than the present alacrity with which they are now *reducing* them *almost one-half* wherever and whenever they feel the competition of our company. Such reductions are not made, however, until our competition is felt.

About the first of January, 1890, a prospectus was sent out setting forth the purposes and prospects of the Electric Mutual Insurance Company and calling for pledges of insurance to secure incorporation and authority to begin business under Massachusetts law. Not less than $500,000 insurance, covering at least 200 separate risks was required. More than double the required amount was pledged, and an organization and incorporation was at once effected. The company issued its first policies on the 15th of May. This report covers the operations to the close of business December 31, 1890—7½ months.

By the treasurer's report you have seen that the outstanding risks amount to the large sum of $2,897,587, the premium on which is $30,320.71—an average rate of about 1⅛ per cent. The average amount of policies is $9,055. The actual cash assets, after paying every dollar of taxes, expenses (including costs of organization, equipment of office, etc.) and losses, amount to $18,907.04, a result, we believe, that is unprecedented in the formation of mutual fire insurance companies.

Not a risk has been assumed that has not either been personally examined by a representative of the company, or the fullest detail and description submitted by the member insuring, in writing, upon blanks of the company provided for the purpose. Not a risk is outstanding that, has not been improved electrically (where improvement was needed), nor that is seriously exposed or without good facilities for extinguishing fire. Nothing can better attest those facts than the statement that not a dollar of loss has occurred on any station insured.

If the experience of the company during the first eight months continues to the end of the first year, we shall be able to pay back to members 50 per cent. of the premium paid for their policies, and add to our reserve besides. Your directors have confidence to feel that so soon as our volume of premiums shall have grown large enough to reduce the ratio of expense to that of the "Factory Mutuals" (about 10 per cent. of premiums) dividends on profits can be made on expiring policies equal to that paid by those companies, which averages nearly 75 per cent. But if *no dividends* were anticipated from the company, your directors feel that a large part of its mission has been accomplished in the material lessening of rates which it has already caused, the average prevailing rate of "board companies" previous to its advent having been about *two* per cent., while, as shown by your treasurer's report, our average is but a trifle over *one* per cent., and we have compelled the board companies to make similar reductions. We predict that they will bid still lower.

The fact should be borne in mind that their seeming magnanimity in reducing their rates will only last while the competition does. To the importance of sustaining the company as a competitor and controller of rates, should be added and considered the fact that insurance upon the mutual plan adopted by us will be furnished at *cost*, shorn of all the expensive machinery and toll-gathering in the way of agents' commissions, such as pertains to the agency system of stock insurance. Of every dollar in premium charged for stock policies, *twenty-five per cent.* does not reach the companies. A still further deduction must be made for expenses, and a profit must be secured for *capital* invested, which is surely not needed to pay for *isolated* electric plants that do not burn each other. Capital *is* needed, however, when the great mercantile or business centres of cities burn up and destroy hundreds of risks for each company—hence the absolute necessity for large capital with companies doing a miscellaneous business. It should be still further considered that the agent who secures electric risks and receives for his compensation a *commission* on the premium collected, has an incentive to take risks with *less caution as to desirability* than he would if his sole aim were the welfare of his company and the interests of the insurers therein.

Stock companies are not prone to furnish insurance any great length of time at *less* than cost, and in view of the facts presented your board feels that you will not long hesitate as to which system offers the more favorable prospects.

We are pleased to say that a most satisfactory arrangement for exchange of business with several of the factory mutuals was concluded shortly after we began operations, and by which arrangement surplus insurance secured by this company, amounting to over one and one-half million dollars, has been placed with those companies at the same rates charged by this company. In return about eight hundred thousand dollars insurance on isolated manufacturing properties fully provided with automatic sprinkler equipments, pumps, hose, etc., insured by them, has been placed with this company.

We could ask no stronger endorsement of our methods and management, not of the desirability of electrical risks, than that which is manifested by the ready alliance of those companies with us. Their record will seem marvelous to those not familiar with it. The first of those companies began over forty years ago and there are now about twenty-five of them. They insure the large cotton, woolen, paper, metal and other manufacturing corporations in the Eastern and Middle States, and to considerable extent in the South and West. Their insurance aggregates over *five hundred million dollars* annually, the cash premium averaging about one per cent. After the payment of losses and expenses the profits have enabled them to pay back to each policy-holder an average of about *seventy-five* per cent. of the cash premium paid for the policy, so that the actual cost of insurance has been only *one-quarter of one per cent. or less*, annually.

They have in the meantime reserved of their earnings from year to year, funds ranging from $50,000 to $900,000 each, thus making the contingency of an assessment so remote as to hardly be a factor in their calculations. In order, however, that they may be in position to pay their losses even under *unprecedented and unexpected disaster*, and to meet the claim of competitors "that they have no *capital*," they have a "contingent, or assessment liability," which is limited to five times the cash premium. Their loss-paying resources are, therefore, about six times their annual premium receipts, as they have always at least one year's premium in hand. It is perhaps needless to say that in their whole existence (dating back forty years) they have never called upon the assessment obligations.

Precisely the same plan was adopted in the formation of the Electric Mutual.

The closing months of 1890, witnessed the retirement (either voluntarily or upon compulsion of State authority) of about twenty so-called "Mutual" fire insurance companies in the Western States. A majority of them have been *masqueraders* under the popular name of mutual, for, in fact, their business has not been confined to any particular class of risks nor conducted upon any of those principles that have achieved such successful and satisfactory results in the New England States; but on the contrary, their risks have mostly been secured through "brokers," on the large mercantile and miscellaneous properties of the cities, and almost wholly at rates ridiculously inadequate for *such hazardous risks*. The inevitable result of securing business through such channels is to get those risks that have been rejected by well managed companies, and in addition to that fact and the extreme unprofitableness of such business at the low rates obtained, the "brokers" have taken their toll of 25 per cent. or more from the premium. Investigation has found "crookedness" at the bottom of some of those companies. Our reference to the subject in this report is to call the attention of our members to the distinction between legitimately conducted mutual insurance and the premium-gathering masqueraders conducted or supported by "brokers" whose only interest in the concern is the "commission" they can reap by having the premium pass through their hands.

Many of the electric stations throughout the West we find have been compelled to insure with those concerns by reason of the excessively high rates imposed by stock companies and their reluctance to take the risks even at their own rates. We incline to the belief that the life of many of the Western mutuals has been prolonged by the profit yielded from premiums on electrical risks, which they freely took, *not* through any wisdom of choice, but simply because of the premium offered.

Several fires have occurred in electric stations, but nearly all have been traceable to carelessness of construction, or failure to provide any facilities for the extinguishing of fire, faults due wholly to the unusually rapid development of the industry. A more deliberate, permanent, and extensive era of construction has set in and the mistakes and neglects of the past are not being repeated.

Your board feels that you and those engaged in electrical development generally, will not fail to appreciate the good results that will follow, and the fire losses that may be avoided by, the dissemination of practical and valuable ideas pertaining to safety, through the intelligent inspection of its risks by an insurance association devoting itself especially to the electrical business. The excellent results obtained by the factory mutuals have been due to the avoidance of "normal hazard" by their careful selection of risks, and intelligent inspection of the same, coupled with the interest that each insurer has in the welfare of the companies.

There is surely no other industry whose best interests can be served to so great a degree by the absence of fire loss as can the electrical; and therefore we feel confident of the wisdom shown in following the lead of those mutual companies whose plans we have adopted and with which we are so agreeably working.

---

[1] Presented to the Board of Directors, January 20, 1891, by S. E. Barton, president.

The business written by the Electric Mutual thus far in January swells its premium income to thirty-four thousand dollars, with every indication that the month will show an increase over the preceding month, which has been the case with each month since we organized. Adding the normal increase of new business to the renewals after one year shall have been passed, there is good reason to anticipate not less than one hundred thousand dollars premium income during our second year.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JAN. 27, 1891.

Accumulators:—

Secondary Battery, C. F. Brush, 445,422. Filed June 9, 1881.

Claim 1 follows:

The method of making a secondary battery element, consisting in producing on a suitable body, frame or support a coating or filling of electrically-deposited spongy lead, then immersing the frame or support thus coated in a battery fluid in which said coating is insoluble, and peroxidizing the coating by electrical action.

Alarms and Signals:—

Electric Bell, J. F. Wollensak, 445,295. Filed Sept. 29, 1890.

The bell has independently adjustable magnet-spools movable toward or from the armature.

Circuit Controller and Alarm, C. M. Woolcott and Albert E. Wilmot, 445,306. Filed Oct. 16, 1890.

Especially applicable to the detection of leaks in automatic sprinklers for extinguishing fires, but applicable to other similar purposes. Claim 1 follows:

A circuit-controller of a conducting material which is dissolved or softened by water, in combination with circuit terminals electrically connected thereby.

Electric Guest-Call, A. Striemer, 445,341. Filed July 29, 1890.

Contains a rotating cylinder provided with a spiral rib, a series of call-bells and a battery in partial circuit with the cylinder. and a series of springs arranged to be successively engaged by the rib on the cylinder, and wires connected with the bells and arranged to be connected with any of the springs.

Leak Detector for Pipes. A. H. Brown, 445,495. Filed Sept. 20, 1890.

Relates to detectors as shown in same inventor's patent No 401,409, April 16, 1889. Applicable especially to fire extinguishing sprinklers.

Conductors, Conduits and Insulators:—

Electric Cable, J. C. Reilly, 445,234. Filed May 20, 1890.

An anti-induction cable. The several conductors are systematically, and at regular intervals, displaced as regards the contiguous parallelism of any given pair, reducing the contiguous parallelism of any two conductors to a minimum.

Electric Cable Connector, S. Bergmann, 445,365. Filed July 24, 1890.

For splicing sections of cables or conductors abutting end to end. Consists of a tapered metal strip which is wound about and soldered to the conductors, the wide end of the strip being first applied to the joint.

Dynamos and Motors:—

Electro-Magnetic Motor, N. Tesla, 445,297. Filed May 20, 1889.

Improvement in alternating current motors of the type previously patented by Mr. Tesla, in which two opposite poles of the field magnet, say in a four-pole machine, have primary coils, connected in the main circuit and also secondary coils which are closed through the coils on the other two field poles, and having an armature of closed coils; the difference in phase between the alternations of current in the primary and secondary windings serving to shift the polarity and cause rotation of the armature. The claims of the present patent include the difference in electrical character, resistance or length of the primary and the secondary field windings.

Commutator-Pattern, P. F. Lenhart. 445,319. Filed June 17, 1890.

A pattern for casting all the metallic sections of a commutator, or dymamos or motors, at one operation.

Regulator for Dynamo-Electric Machines, J. H. Holmes, 445,448. Filed May 14, 1890.

Relates to maintaining a constant difference of potential at the terminals of a dynamo supplying currents for lighting railway trains.

Claim 1 follows:

In electric machinery for lighting railway trains, a generating-dynamo the field-magnets of which have, in addition to the ordinary shunt-wound exciting circuit, a supplementary circuit. connected to an independent source of current, and having in series with it the armature-circuit of a regulating-dynamo driven at the same speed or subject to the same degree of speed-variation as the generating-dynamo, the electro-motive force of the regulating-armature being made to oppose the electro-motive force of the independent source of current, so that its variation in proportion to the variations of speed will practically maintain constant the electro-motive force of the dynamo.

Electric-Motor, W. M. Dresskell, 445,499. Filed June 9, 1890.

The invention consists of a construction and connections adapted to enable the windings of the armature to be connected up in series or in parallel at will.

Commutator Brush-Holder for Electric Motors, G. H. Condict, 445,521. Filed Apr. 18, 1890.

Particularly applicable to motors employed for traction purposes, where there is difficulty in properly keeping the brushes in adjustment on account of jarring. The holders, movable to or from the commutator, are provided with a screw-threaded tension-rod for drawing them toward each other, and an adjusting nut supplied with a weight whereby the nut may be maintained in any predetermined position and prevented from turning by the jarring of the machine.

Galvanic and Thermo-Electric Batteries:—

Galvanic Battery, W. A. Crowdus, 445,425. Filed Oct. 7, 1890.

Relates to two-fluid batteries in which a porous diaphragm or partition is employed, and has for its object to reduce to a minimum the internal resistance without increasing the osmosis of the fluids. The inventor employs, in conjunction with a non-conducting porous partition, a conducting porous partition, arranged against, and co-operating with a non-conducting partition, thus reducing the thickness of the latter.

Lamps and Appurtenances:—

Electric-Arc Lamp, J. A. Hayes, 445,176. Filed April 23, 1890.

An arc lamp in which both the upper and the lower carbon are fed. The feed is effected through the movements of a pinion, rack and a ratchet wheel.

Electric Cut-Out, J. S. Potter, 445,253. Filed Aug. 16, 1890.

Especially applicable to incandescent lamp circuits, and includes a safety fuse.

Electric Switch, G. Cutter and C. G. Armstrong, 445,310. Filed July 31, 1890.

A quick-acting or "snap" switch, for electric lighting circuits, particularly adapted for circuits of from four to six incandescent lamps.

Cut-Out, S. Bergmann, 445,362. Filed Jan. 25, 1890.

For incandescent electric lamps.

Electric Cut-Out, S. Bergmann, 445,363. Filed Feb. 17, 1890.

For incandescent lamps. Consists in a pendent or other fixture tube or arm having a seat adapted to receive a cut-out, and a cut-out removably secured in said seat.

Key for Electric Cut-Out, S. Bergmann, 445,364. Filed May 5, 1890.

For incandescent electric lamps. Intended to provide a cut-out to the shaft of which any key or finger piece may be attached.

Manufacture of Carbon Filaments, W. M. B. Keen and W. F. Haarmann, 445,374. Filed June 19, 1890.

Intended to produce a filament strong, elastic, flexible, durable and very dense in structure. The inventor describes the principle of the invention as similar to that employed in the manufacture of beer. The process consists in saturating a ligature of vegetable or animal fibre, such as cellulose or silk, with a mixture of hops and a solution of saccharine matter and glue, concentrating the mixture by boiling, drying the saturated material, and then carbonizing.

Miscellaneous:—

Thermal Cut-Out, A. Barrett, 445,217. Filed Dec. 5, 1890.

Especially applicable for the protection of telephone and telegraph apparatus from injury by too powerful currents. An attenuated and fragile conductor, included in the circuit to be protected, is attached to a strong spring, or equivalent device, capable of rupturing it, but is protected from the action of such spring under normal conditions by being embedded in a mass of material which is ordinarily solid but which will soften or disintegrate under the influence of heat.

Coin-Controlled Electric Coil, E. J. Colby, 445,220. Filed Oct. 17, 1889.

A "nickel in the slot" shocking machine.

Railways and Appliances:—

Motor-Truck for Cars, J. A. Brill, 445,308. Filed Oct. 3, 1890.

Claim 7 follows:

In a pivotal car-truck, the combination of a car-body mounted upon a truck, said truck having a frame, forward and rear axle boxes, axles and wheels, a pivotal centre directly over the centre of one of the axles, a motor sleeved to the axle over which the pivoted centre is located, and springs for supporting the free end of the motor mounted upon the truck frame.

Turn-Out for Electric Railways, R. M. Hunter. 445,409. Filed June 29, 1887.

Embraces turn-out devices for the conductors on a single track railway and a pair of trolley wheels riding on top of the conductor.

Electric Connection for Track-wiring, S. H. Short, 445,479. Filed Oct. 10, 1890.

Claim 3 follows:

The conducting system or track-wiring, comprising a main-track wire or wires, branch wires, and grooved or open-sided connectors having the said wire fixed in the grooves or sockets of said connectors, which thus couple the branch-wires with the main-track wires.

Conductor-Switch for Electric Railways, F. J. Sprague & J. F. S. Branth 445,515. Filed Sept. 27, 1888.

Relates to frogs or switch-plates for crossing or branching lines. The switch plate has a movable deflecting-rib for guiding the contact wheels across its surface; the switch-plate is provided at its extremities with depressing-ribs to avoid impeding the movement of the trolley when entering the switch-plate.

Telegraphs:—

Telegraph Key, J. Doggett, 445,442. Filed July 28, 1890.

A combination key and sounder.

Telephones and Apparatus:—

Telephone, E. Noriega, 445,475. Filed Oct. 2, 1890.

The transmitter has a diaphragm of wood or similar material with annular electrodes sliding upon a cylindrical electrode.

Legal Notes.

SUBWAY INJUNCTION IN NEW YORK.

Mr. Edward Henry's application for an injunction to restrain the Board of Electrical Control from making any contract with the Empire City Subway Company, Limited, for the construction of subways, and from taking any action toward relieving the Consolidated Telegraph and Electrical Subway Company from any of its obligations under its contract until the same should have become ineffectual, has been granted by Judge Truax, of the Superior Court.

Although the action was brought by a taxpayer, the high-tension electric lighting companies were the real parties interested in having the board restrained from making the new contract under which the high and low tension systems, it was alleged, were to be separated.

SAN ANTONIO, TEX.—The Alamo Electric Street Railway Co. has been granted an extension of time of four months in which to complete the railway for which a franchise was granted last May. The company claims that the delay was occasioned by no fault of its own, but through its inability to get the rails, etc., at the time specified in the contract, and many other unavoidable causes.

THE
Electrical Engineer.

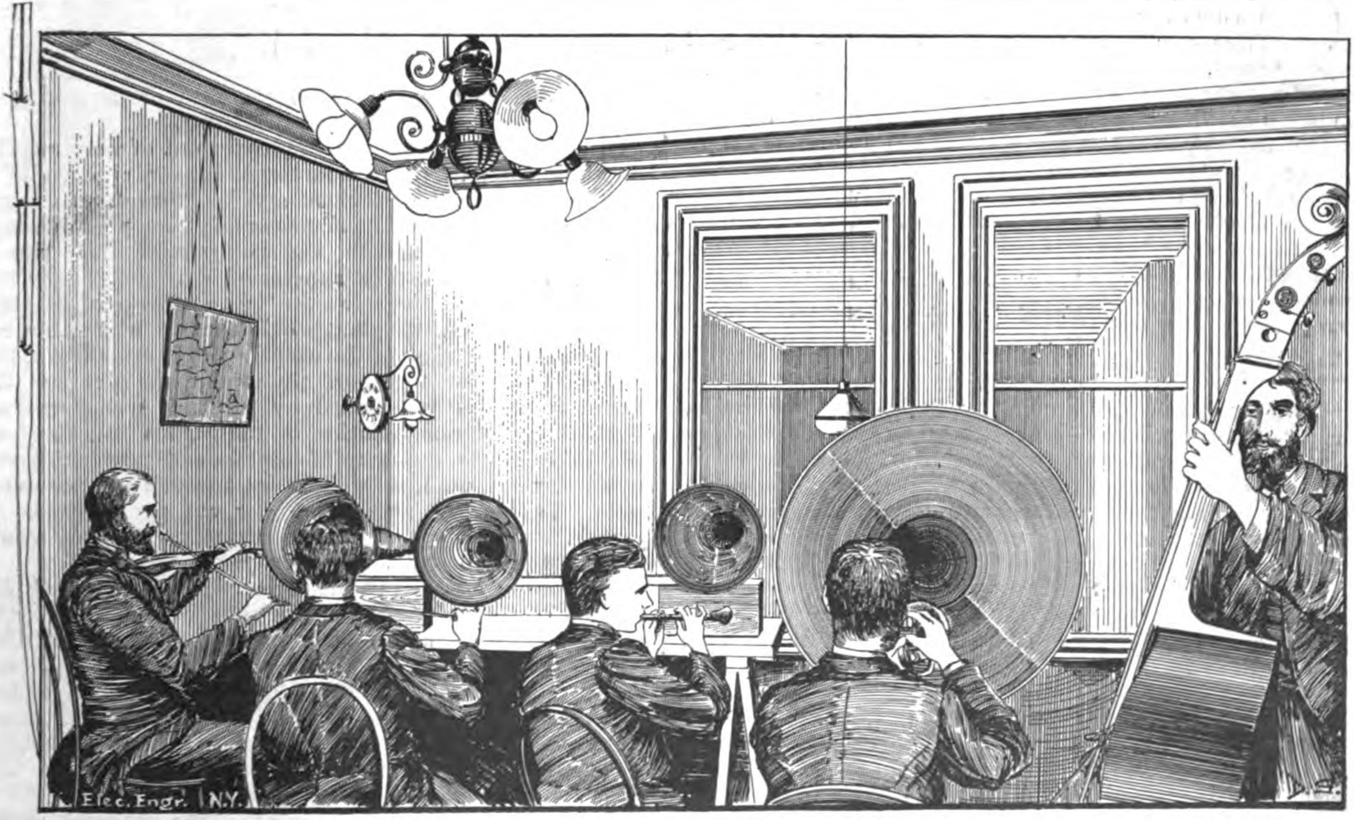
Vol. XI. FEBRUARY 11, 1891. No. 145.

LONG DISTANCE TELEPHONE CONCERTS.

ONE of the most interesting developments of telephone work is that which is now steadily going on—the transmission of orchestral music over long distances. Our readers will recall the large measure of success attained during the exhibition of the Women's Exchange at the Lenox Lyceum last winter, when, besides the transmission of music from the local theatres, Boston contributed to the entertainment by telephone, in the shape of music and recitations.

This work has been carried on by the American Telephone and Telegraph Co., known as the "Long Distance Company," under the direct supervision of their able engineer and electrician, Mr. F. E. Pickernell, and the results obtained with but a comparatively short experience in so difficult a field are exceedingly gratifying and give promise of still greater success in the near future.

In a lecture recently delivered in the Town Hall at Newton, Mass., Mr. Pickernell described the methods employed in the transmission of music by telephone. His remarks were very forcibly illustrated by the reception in the lecture hall of music transmitted over the Long Distance lines from the Telephone Building, at No. 18 Cortlandt street, New York, and our engraving, made from a photograph taken at the time, shows the arrangement of the performers.



Elec. Engr. N.Y.

A Long Distance Telephone Concert.—Performers in New York, Audience at Newton, Mass.

In transmitting music of this kind, it has been found desirable to have a separate transmitter for every instrument, and further, that, where a considerable number of instruments are used, it is necessary to so arrange the induction coils that their joint resistance will bear a fixed ratio to the resistance of the receiving instruments and line, all the induction coils being connected by the same line in multiple series.

For this class of work the storage battery is admirably adapted for operating the transmitters, and by using cells of this type, it is possible to run 20 long-distance transmitters from the same battery without drawing a current sufficiently heavy to injure the storage battery.

By using separate transmitters for each instrument, due prominence may be given to each of the instruments at the receiving end. If one transmitter is arranged to transmit music emanating from 50 instruments, it has been found that it must be so adjusted that the average result will be fair. Under these conditions, the lighter violin parts are heard but very indistinctly, while the heavier parts produce very great noise, but the purity of the sound is affected. This of course gives very unsatisfactory results.

At the receiving station, when it is desired to fill halls of considerable size, as many as six loud-speaking receivers are used. These are connected in multiple series, so that their joint resistance bears a definite ratio to the resistance of the transmitters; these are distributed about the hall, being usually attached to the chandeliers.

On the occasion above referred to, the music transmitted from New York over a distance of 250 miles was listened to by an audience of over 1,000 persons.

When we add that similar entertainments have been given with music transmitted over a distance of no less than 460 miles it will be clear that if the same progress is made in the future as that characterised by the work of the last few months, the telephone will occupy an important position in our future entertainment, both public and private.

NOTES ON ELECTRO-DEPOSITION.

BY

Gilbert Wilkes.

I HAVE read with much interest the articles on "The Arrangement of Vats in Electro-Deposition," by Mr. C. O. Mailloux, in the recent issues of THE ELECTRICAL ENGINEER, and think that the subject is of sufficient importance to justify some further attention, as well as a few remarks upon the above mentioned articles.

Let $R =$ resistance of the liquid in one vat.
$r =$ " " plates "
$\varepsilon =$ counter electromotive force of one vat.
$E =$ potential difference between the terminals of one vat.
$C =$ current.
$W =$ energy consumed.

Equation (2) of the articles mentioned above gives—

$$E = C\,(r + R) + \varepsilon.$$
$$= C\,(r + R + \rho).$$

The second part of this equation is evidently incorrect. $E = C\,(r + R) + \varepsilon$ expresses simply the condition in a circuit in which there is not only an ohmic resistance but a true counter electromotive force. Were $E = C\,(r + R + \rho)$ correct, there would be no part of the equation which would not vary with the current, and the values of $(R + r)$ and of ρ could not be separated. This is not the case, as in fact the way in which the value of ε is determined is by taking advantage of the fact that it does not vary with the current. This is accomplished by taking successive readings of E with different values of C. Thus, using primes to denote a second case

$$E \;= C\;\;(R + r) + \varepsilon \qquad (a)$$
$$E' = C'\;(R + r) + \varepsilon \qquad (b)$$

Solving, $$\varepsilon \;= \frac{C'\,E - C\,E'}{C' - C.} \qquad (c)$$

Considering that ε, the quantity to be obtained, under proper conditions, is less—and often much less—than 10 per cent. of the quantities observed and from which it is obtained by a difference method; that the conditions are necessarily unfavorable to accurate observation, and that the material attacked at the anode is constantly varying, the values of ε do not vary more than one would expect.

In the case of copper refining by electrolysis, ε must of necessity be small and will, in general, be opposed to the flow of current. The purer the plates, the smaller will ε be, which will assist in accounting for the various values given by different writers. Also, the presence of other metals, such as antimony, bismuth, arsenic, etc., must affect the value. We all know that two pieces of the same copper wire, plunged in acidulated water and put in circuit with a sensitive galvanometer, will give a decided deflection. Imagine then the effect of small quantities of all of the above metals, native and as compounds in an acidulated solution, upon a counter electromotive force of a few hundredths of a volt, and there will be no difficulty in understanding variations in ε—small in themselves, but proportionately large in comparison with ε.

A simple demonstration of the fact that a practically unlimited amount of copper *may* be refined with a given appreciable power can be derived as follows:—

Let the total number of vats $= n\,m$, arranged in n series of m vats connected in parallel. Then, keeping C constant

$$E_{n\,m} = n\;C\,\frac{R + r}{m} + n\,\varepsilon \qquad (d)$$

$$W_{n\,m} = n\;C^2\,\frac{R + r}{m} + n\,\varepsilon\;C \qquad (f)$$

$$\frac{W_{n\,m}}{W} = \frac{n\;C^2\,\frac{R + r}{m} + n\,\varepsilon\;C}{C^2\;(R + r) + \varepsilon\;C} = \frac{n\;C\,(R + r) + m\,n\,\varepsilon}{m\,[\,C\,(R + r) + \varepsilon]}$$

$$= n\left\{\frac{1}{m} + \left(1 - \frac{1}{m}\right)\frac{\varepsilon}{E}\right\} \qquad (g)$$

From this equation, it is evident that if n is kept constant (say equal to unity) and m be indefinitely increased, $\frac{W_{n\,m}}{W}$ will constantly diminish, the limiting value of the ratio being (with $n = 1$) $\frac{\varepsilon}{E}$, which, with nearly pure metal under treatment will become a very small quantity. The deposit, however, remains the same, depending only upon C.

Take $E = .5$ volt and $\varepsilon = .05$ volt, which conditions may easily be reached, and let $n = 5$ and $m = 9$. Then denoting amounts of deposit in the same time by D and $D_{5,9}$, and keeping C constant,

$$\frac{W_{5,9}}{W} = 5\;\left\{\frac{1}{9} + \left(1 = \frac{1}{9}\right) \times \frac{1}{10}\right\}\;;\text{ or,}$$

$$\left.\begin{aligned}\frac{W_{5,9}}{W} &= 1,\\[1ex] \frac{D_{5,9}}{D} &= 5,\end{aligned}\right\} \qquad (h)$$

Thus, while we have increased the rate of deposit fivefold, the power remains constant.

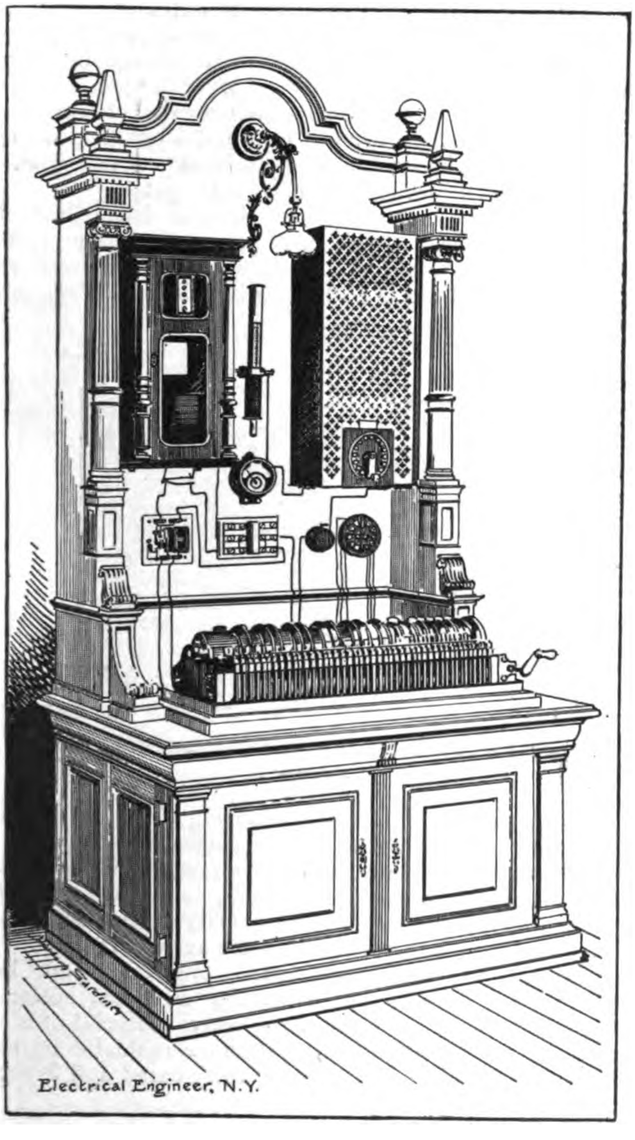
Of course all of the foregoing leaves out of account the question of loss in the conductors. In the citation of a practical case, in the previous articles, the reference must be to some other form of plant than one for copper refining. For, if n equals 100 and the vats be arranged in n series of n vats, as stated, the total number of vats will be 10,000 (not 1,000), and, if the reference is to a case of electric refining of copper, this plant would contain a greater capacity than that of all of the electric copper refineries in the United States put together. In commercial practice the size of the vats is determined by practical considerations (such as ease of manipulation of plates, not too frequent renewal of plates, economy of total cost of vats for a given anode surface, etc.), as well as by theoretical considerations. Taking the production per vat per hour as 1½ pounds, which is not a large estimate, 10,000 vats would supply 360,000 pounds of pure copper per day.

Cases are mentioned in the former articles of good deposits with 5 volts per cell and with a current density of 200 amperes per square foot. I do not doubt the possibility of obtaining such results in electro-deposition with pure anodes; but in refining copper containing the impurities usually met with, I fear that such practice would prove disastrous to the purity of the deposit. A high electromotive force at the terminals of the vat is of course also to be avoided on account of the losses due to decomposition of water. Cases may however arise, for example, in the refining of gold alloys, when the value of the metal in the vats will overbalance all other considerations in the laying out of the plant.

One very prominent point has not yet been touched upon at all—the source of the energy—the electric generator.

By increasing the number of vats in squares and arranging them electrically in squares, how is the generator affected?

Take, for example, a good sized plant of 100 vats, each vat producing 1¼ pounds of refined copper per hour. Each vat would require 385 × 1¼ amperes = 480 amperes. Should the vats be arranged in a square, there would be required a generator of about 48 kilowatts capacity, giving 4,800 amperes at somewhere in the neighborhood of 10 volts, more or less, depending upon the resistances of the vats and of the conductors. Such a machine would give rise to no end of trouble. It would cost enormously in proportion to its capacity, and in order to be able to run 24 hours per day steadily, it would have to be much larger than the above capacity; every imperfect connection would be an example of an electric heater and cause a large loss, while the expense for conductors would be great.



Electrical Engineer, N.Y.

Fig. 1.—Switch Board of Telegraph Storage Battery Plant, Berlin, Germany.

Now suppose these 100 vats arranged in series. The generator would have to supply 480 amperes at somewhere about 75 volts. This machine can be bought from stock at standard prices; a bad connection will not cause the great loss that it did before, and there will result a great saving in copper conductors. In short, we shall have a practical system. Leakage is the limiting condition in the matter of voltages, but in a properly constructed plant, in spite of large vats of liquor and creeping salts, no trouble will result from this cause at the above moderate voltage.

STORAGE BATTERIES IN THE MAIN TELEGRAPH OFFICE AT BERLIN.

As far back as October, 1889, the first attempts to operate their lines with current derived from storage batteries was undertaken by the electricians of the German government telegraphs. The results obtained were so satisfactory that the plant has now been considerably enlarged, so that at the present time 237 circuits are operated by this method. Of these 93 are employed for the Hughes printing lines, 53 being overhead and 40 underground; and 144 operating the Morse system, of which 130 are overhead and 14 underground.

The accumulator employed at the present time is placed in the cellar of the main building and is arranged in four rows of 40 cells each. Each group of 40 cells constitutes a battery by itself, the circuits of which lead independently to the switch-board in the main office. The cells contain 3 positive and 4 negative plates each, and have a capacity of 52 ampere hours and can be discharged at the rate of 10 amperes. In the operation of the cells two groups are always operated in series, while the third is held in reserve or can be charged at the same time. In consequence, arrangements had to be made by which it was possible to cut out each group and to substitute therefor the reserve battery, and in order to effect this without interruption to the service, the reserve battery has to be placed first in parallel with the battery which it is to replace and the latter then cut out of circuit.

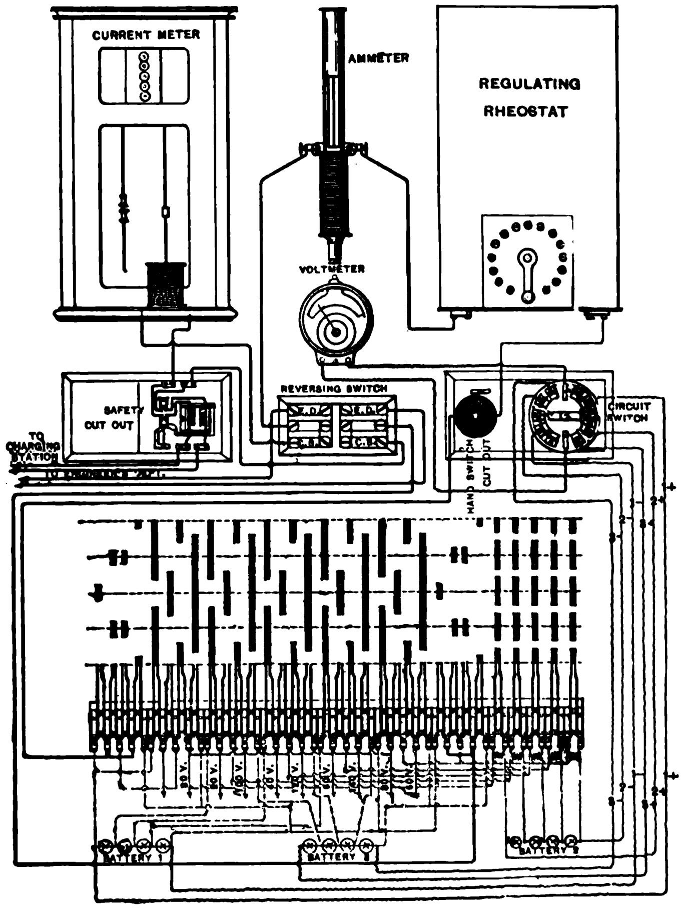


Fig. 2.—Diagram of Telegraph Storage Battery Plant, Berlin, Germany.

The manner in which this was accomplished will be understood from the accompanying illustration. The entire switching for this purpose is accomplished by means of a cylinder provided with contacts which make connections with clips, as illustrated in Fig. 2, which shows the arrangement of the contacts on the cylinder developed as a flat surface. The cylinder is operated by means of a crank and worm wheel, shown in Fig. 1, which represents the entire installation at the main office.

As will be seen in the diagram, Fig. 2, current for charging the batteries is obtained both from the dynamo in the telegraph office in the engineer's department and also from the central station situated at some distance from the telegraph office. The circuits lead first into a safety cut-out which is so arranged that if the current exceeds 12 amperes the circuit is broken. From this point the current passes through an electric meter of the Aron type to a switch with six segments, designated as C S; by means of the bridge pieces the latter are connected with the storage battery S B. From this point the charging circuits lead to the ammeter, to the regulating rheostat, to the hand switch, and to the corresponding terminals of the main cylinder switch. To the blocks marked E D of the switch two wires are connected which lead to the engineer's department, so that by connecting the bridge pieces to the segment marked E D, the charging current is obtained from the engineer's department. The voltmeter is so arranged that by means of a switch it can be connected to any of the three battery groups.

In the lower part of the diagram, Fig. 1, there are shown a number of circuits marked 80, 20, 100 volts, etc. The object of these circuits is to take current of the designated E. M. F. from the cylinder switch. They lead to heavy brass contacts and are connected to the German silver resistances placed in circuit with the battery switch. The resistances are so arranged that for every volt E. M. F. one ohm of resistance is included in the circuit. Thus a circuit requiring an E. M. F. of 160 volts has 160 ohms included in it. The arrangement is such that each underground circuit has its special safety resistance, while not to exceed 5 overhead lines are joined to a single safety resistance. By this arrangement if a short circuit should take place between the cylinder switch and the battery switch, the current could never exceed one ampere, and if such a short circuit takes place an alarm is immediately set in action. This alarm is given as follows: In the earth connection there is inserted a resistance of .5 ohm, and as a shunt to this a polarized Siemens relay with its coils in parallel. The tongue of the relay is not affected by even the heaviest telegraph currents, but a current of .5 to 1 ampere brings the tongue in operation and sets the alarm off. Although no occasion has yet arisen in which this alarm was given, it is nevertheless tested every morning to see whether it is in working order.

Experiments have shown that with the 237 circuits connected, the mean strength of the current varies between .2 and .3 amperes, which would give about .001 ampere per circuit, which agrees very well with former experiments. The small quantity of current required shows that even the smallest sizes of storage batteries required for electric lighting are far too large for telegraphic purposes, and that smaller and simpler cells are quite sufficient, in consequence of which the German telegraph department has undertaken the construction of a special telegraph storage battery. Continued experiments have shown that during ten days' operation the potential of the battery does not drop more than 2½ to 3 volts.

POLICE TO BE USED AS LINEMEN.

In view of the recent destruction of the police telegraph wires in New York by the storm, and the difficulty experienced in securing a force of linemen, the captains of the various precincts will be asked to find out and enroll the men in their squads who may be serviceable for such duty in future emergencies.

Juvenile Labor in Electricity.—The New York State factory inspector, Mr. James Connolly, recommends in his annual report that children under 14 years of age be prohibited from employment in mercantile houses, telegraph, telephone and messenger service.

THE ERNST STORAGE BATTERY SYSTEM.

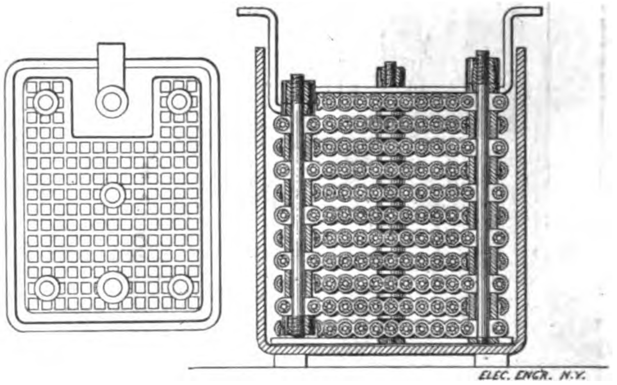
BY

Victor H. Ernst.

Among electricians there is no topic of greater importance than the development of a practical storage system. Such a system would prove of incalculable advantage in electric lighting plants, in the propulsion of street cars and boats, and for numerous other purposes.

The intercirculatory storage battery system, devised by me, is the result of long mechanical experience, enabling me to grasp the difficulties of other systems, and to remedy them in this. The present electrical storage inventions mark, I believe, as great an advance over the present types, as did the triple expansion engine over the old-fashioned slide valve engine. A series of tests and a practical demonstration prove that a gain of at least 20 per cent. in effective power is accomplished by this system.

The numerous experiments of the past decade have demonstrated the uses to which a practical storage system may be put. Heretofore a surface action only has been obtained, one of the greatest difficulties being the retaining of the active material in place during the charging and discharging, and in spite of the concussions incident to use. To this end, plates of various forms have been constructed, having projections, hooks, loops, cavities, etc., but such forms are liable to be quickly destroyed, or else to lack electrical penetration into the active material.



Figs. 1 and 2.—The Ernst Intercirculating Storage Battery System.

Previous to my work little progress had been made toward storing and receiving electrical action by utilizing the inner particles of the active material of a battery plate. In this respect this system is a radical departure, all the material in the plate being fully cured and brought into action.

The system practically combines two fundamental principles involving an absorbent core, having an expansive action. The expansive core of asbestos or other material employed, ramifies through the interior of the active material in such a manner that the active material is kept in close contact with the walls of the plate, giving perfect electrical connections or continuity.

This elastic, expansive and contractile core presents a yielding surface to the active material, so that sudden concussions, as in street-car service, do not crack and dislodge it from the walls of the plate. The absorbent action is also obtained through the medium of the expansible core. As will be seen from the accompanying illustrations, Figs. 1 and 2, the plates are arranged horizontally, with distance washers and rubber bolts, but no lead burning, or soldering of any kind enters into the construction of the cell. The electrolyte circulates by absorption within the active material of the plate, thoroughly curing it in the beginni and leaving it in the best possible condition for receiving and giving out electrical charges.

Owing to the intercirculating action of the electrolyte upon every particle of the active material, it is evident that the main object of a storage system has been attained, namely, the quick preparation of the plates for their work, and their superior efficiency for practical purposes.

It has been found that in a set of 26 cells in use over 18 months, not a bend nor buckle has taken place, nor has any active material become dislodged, which is due to the equalizing action of the asbestos cord during the expansion and contraction of the active materials.

THE REED ELECTRIC RAILWAY SYSTEM.

Among the many workers in the field of electric railway construction, is Mr. E. M. Reed, of Pueblo, Col., who has devised a system in which the trolleys, while operating in essentially the same manner as in the overhead system, are attached to a carriage traveling in a large conduit beneath the surface of the street.

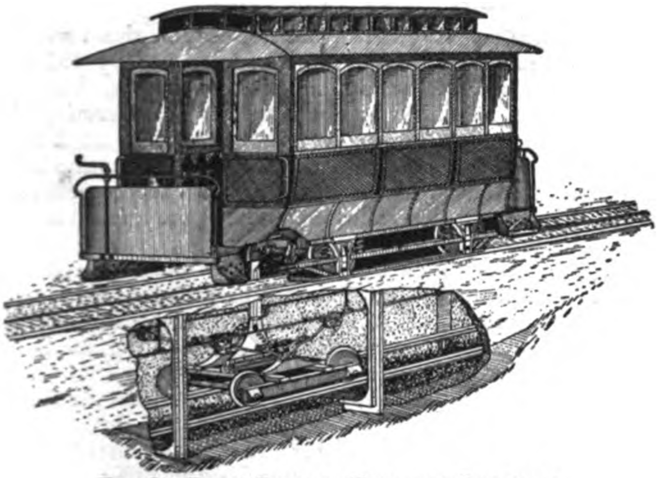


FIG. 3.—REED CONDUIT ELECTRIC RAILWAY.

In the accompanying illustrations, Fig. 1 shows one of the yokes which form the frame work for supporting the concrete walls of the conduit, the upper side portions of these yokes being provided with seats upon which are secured the surface rails. The positive and negative conductors are shown one, on either side of the conduit. These consist of sections of tubing, corresponding in length to the distance between the hangers, where they are sleeved to allow for contraction or expansion due to changes of temperature. They are designed to conduct a current of warm, dry air, which may be forced in at the ends, or at stations along the line, so as to maintain the insulation perfect. At the base of the yoke are seen the rails on which the trolley carriage runs.

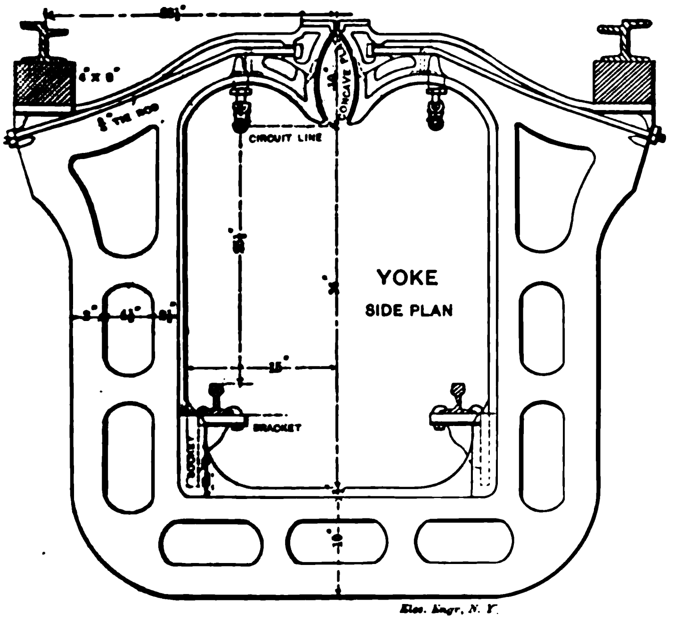

FIG. 1.—REED UNDERGROUND TROLLEY CARRIAGE.

The carriage shown in Fig. 2, consists of a frame mounted on four wheels, which run on the tracks in the conduit. The trolley arms are slightly flexible, and each pair is connected by means of a rod, for the purpose of regulating the pressure of the wheels upon the circuit lines.

In the centre of the carriage will be seen a column, secured to the base plate by means of a hinge, which allows it to tip slightly, and extending up through the surface slot to the motor truck, with which it engages by means of a hinged socket secured to one of the axles. The socket is of sufficient depth to permit a limited play of the column, in case of the car passing over an obstruction. The socket may be raised, and the trolley carriage disconnected, by means of the segments and lever shown.

Fig. 3 gives a view of the conduit, the side being cut away to show the trolley carriage and the means of attaching it to the motor.

The operating expenses of this system when complete are claimed by Mr. Reed to be much less than those of the overhead. A plan is now on foot for the adoption of this system in one of the largest Western cities.

IMPROVEMENTS IN COPPER SMELTING.[1]

Mr. Gilchrist, who, in conjunction with the late Mr. Thomas, developed the basic process in its application to the production of iron, has recently devoted his attention to the smelting of copper, with a view to the elimination of its impurities by similar means. Mr. Gilchrist points out the difference in importance of the application to the two metals, and the results expected from the application of his improved process to copper are rather increased yields than greater purity. It seems likely that both these desirable results may be attained, according to the views expressed at a recent meeting of the London section of the Society of Chemical Industry. It is stated that some enterprising smelters, being satisfied with the prospects, have taken the matter up, and are making the necessary alterations in their furnaces to enable experiments to be conducted on a large scale. The electrical industries are so largely interested in the cheaper production of copper that we hope to learn in due time of the success of the experiments, even though the improvements should be but slight.

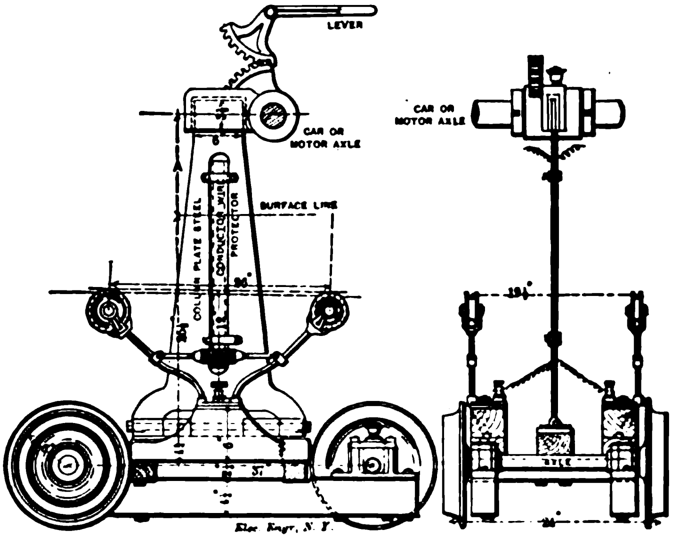

FIG. 2.—REED CONDUIT.

[1] London *Electrical Review*.

A SIMPLE METHOD OF DYNAMO DESIGN.—II.

BY

Thorburn Reid.

(*Conclusion.*)

Suppose a dynamo is constructed by means of Kapp's formula and it is found that the voltage is too low, as will generally be the case. Then the magnetic resistance is too high somewhere, either in the armature, field or air space. Nothing is known as to the degree of saturation of the iron in field or armature, and Kapp's formula does not give us the true resistance either in field, armature or air space. Of course this difficulty might be obviated by simply increasing the number of ampere-turns on the field, but this means added expenditure for copper and possibly more loss of energy. The cross section of the field core might be enlarged, but the armature core might be near saturation, and thus this decrease in the field resistance would not proportionately increase the flux through the armature. The same is true in regard to increasing the cross section of the armature; the field might be too near saturation.

In short, Kapp's formula merely expresses the flux through the circuit as a whole and does not at all show the effect of each part. In the second place, different sizes and types of dynamos are seldom worked with the same degree of saturation and thus a new constant has to be determined for each size or type of machine. The table of constants given on page 121 (second edition), would be fairly accurate if the initial permeability of the iron were 940 and his constant for air correct, and the field magnets of wrought iron. Finally, for cast iron field magnets Kapp's formula is generally nowhere near correct. The number of ampere-turns obtained by means of it has often to be multiplied by 2 or 3, sometimes even by 4 or 5. In such cases it would be just about as accurate to guess at the number of ampere-turns and estimate the proper number by the voltage obtained.

"My friend," remarks our practical man, "I see your point very clearly. These are serious objections to Kapp's formula, but that formula has been of incalculable benefit to me in my work and I do not propose to give it up till I can get a better."

Very well, you have one ready to your hand, if you will only take the trouble to look into it, which is far superior to Kapp's.

In the year following that in which Kapp communicated his formula to electricians, Drs. J. and E. Hopkinson published an account of some experimental investigations made with the help of a formula which was practically that of Kapp, as stated by him originally. They, however, applied the formula more logically, only changing the method of application. Instead of obtaining the magnetic resistance in the different parts of the circuit, they deduced the E. M. F. required to drive the necessary number of lines through the magnetic resistance in the different parts of the circuit. Their test was made with an actual machine already built and their object was, as stated, to obtain the relation between the E. M. F. required and the E. M. F. delivered from theoretical considerations, and then to compare this with the true relation obtained experimentally. The primary object of their investigation was not, therefore, the designing of dynamos; but their method, as they no doubt foresaw, is an excellent one for the purpose.

Without entering further into the experiments of Drs. J. and E. Hopkinson, I will attempt to give a clear and simple outline of a method which is a modification of theirs, and which I have found very convenient in designing dynamos and other magneto-electric machines, partly on account of its ease and rapidity of application, partly for the reason that it shows very clearly the condition of affairs in the different parts of the circuit; but mainly on account of its accuracy.

The method, of course, presupposes a determination of the saturation curves of the metals used in the different parts of the circuit. At this point the practical man inquires, "How am I going to make such a determination, which requires the most delicate instruments to be set up in a place where they shall be entirely free from all disturbing influences in a factory where the floors are shaking and masses of iron are always being moved about and disturbing currents are everywhere?" I answer from bitter experience that you can not do it. But why try? There are numbers of laboratories throughout the country, at colleges and elsewhere, where such determinations can be made with the greatest ease. The instruments are all there, and the disturbing elements lacking. The samples of metals need not weigh more than a few pounds, and can be easily tranferred. The expense would be as nothing, compared with the benefits accruing, and would doubtless be repaid in a very few months.

Experience has taught me that not only is the variation of the magnetic properties of iron furnished by different makers very much less than one would suppose, but also that the iron furnished by one company at different times is remarkably uniform, the largest variation that I have yet found in the whole magnetic circuit of a dynamo being less than 5%; that variation including also the inaccuracies in the preliminary determination, and in the measurements and workmanship of the machines.

I carried through a set of experiments on the cast iron and steel used in the dynamos of a certain company, some time ago, to determine their saturation curves. The method of experiment was a very simple one, enabling me to get a complete saturation curve in an hour or two. There were no very delicate adjustments, and the apparatus used could be found in any scientific laboratory. The data having been obtained, the curves were carefully plotted out on section paper. The accompanying diagram, Fig. 1, shows the method of arrangement of the curves, the data for which were taken from Hopkinson's paper printed in the *Transactions* of the Royal Society of the year 1885, part second.

The vertical scale represents C. G. S. lines per square inch for every curve and line on the plate. The first horizontal scale represents ampere-turns per inch in length of the magnetic circuit for wrought and cast iron. For convenience in locating the air line, the same scale was made to represent ampere-turns per one-hundredth of an inch in length of the magnetic circuit.

The second scale belongs to the two curves of permeability of wrought and cast iron, and gives the actual numerical value of the permeability. The third scale is used in connection with the line marked "C. G. S. lines per square centimetre," and furnishes a ready means of transforming from C. G. S. lines per square centimetre to C. G. S. lines per square inch, or vice versa. The last scale is used in the same way to transform from Kapp lines per square inch to C. G. S. lines per square inch, and vice versa.

To explain the use of the last two scales, first, suppose we want to find out how many C. G. S. lines per square inch correspond to 13,000 lines per square centimetre. Finding 13,000 on the third scale, and following the vertical ordinate to its intersection with the "C. G. S. lines-per-square-centimetre" line, we read on the vertical scale 84,000 lines per square inch. We can then, if we wish, reduce to Kapp lines per square inch by means of the dotted line, the intersection of 84,000 C. G. S. lines per square inch with the dotted line giving us 14 Kapp lines per square inch. Thus our original 13,000 C. G. S. lines per square centimetre are equivalent to 84,000 C. G. S. lines per square inch, or to 14 kapp lines per square inch. This affords us a means of reducing C. G. S. lines per square centimetre or Kapp lines per square inch to C. G. S lines per square inch.

Now to obtain the ampere-turns, find on the vertical scale the number of C. G. S. lines per square inch you intend to use, obtain its intersection with the saturation curve of the substance in the magnetic circuit, then on the horizontal scale read the number of ampere-turns per inch in length of the magnetic circuit, multiply this number by the length of the magnetic circuit in inches, and you have the total number of ampere-turns required. If the substance in the magnetic circuit be air, you must first multiply the number of ampere-turns obtained from the scale by 100.

The use of these curves in designing dynamos is just as simple. Suppose, for instance, that we know the length and cross section of the different parts of the magnetic circuit of the dynamo in inches, the total number of lines that must traverse the armature to give the requisite E. M. F., and the leakage coefficient. First divide the total number of lines traversing the armature by its cross section. To obtain the number of lines per square inch, from the curves, obtain the ampere-turns per inch and multiply by the diameter of the armature. We thus get the number of ampere-turns required to force the total number of lines through the armature. Next, divide the total number of lines by the cross section of the air space. Find the ampere-hours per inch in length from the curve and multiply by 100 times the double depth of the air space, the length of the air magnetic circuit being twice the clearance between the armature core and the surface of the field poles. The result is the number of ampere-turns required to force the total number of lines through the air space.

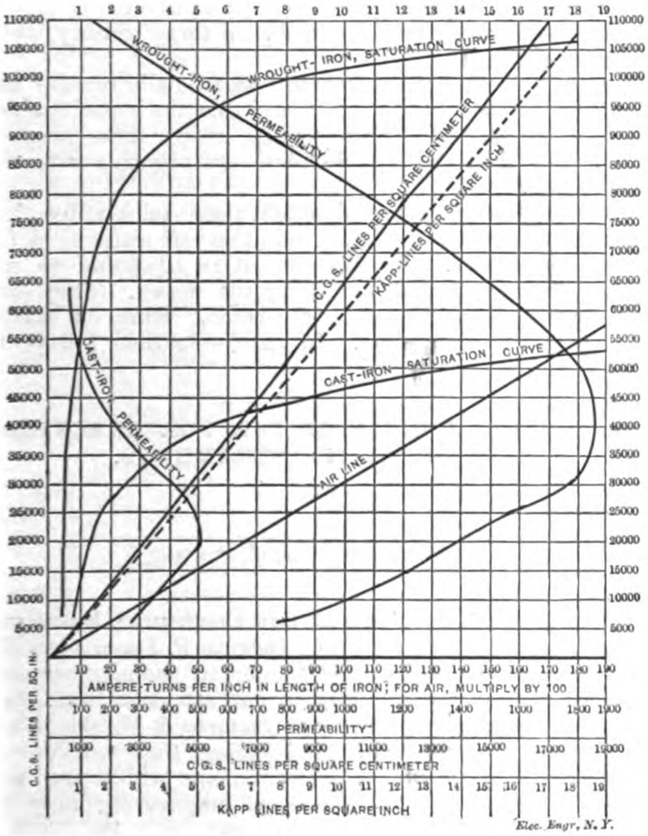

Fig. 1.—Magnetic Curves For Iron and Air.

Next multiply the total mumber of lines by the leakage coefficient, which is the ratio of the number of lines traversing the field to those traversing the armature. This gives us the total number of lines traversing the field magnets. Divide by the cross section of the field to obtain the C. G. S. lines per square inch. From the curves obtain the ampere-turns per inch in length. Multiply by the length of the field circuit in inches and you have the number of ampere-turns required to force the requisite number of lines through the field. Finally add together the ampere-turns thus obtained for the armature air space and field, and you have the total number of ampere-turns required for the dynamo.

Now as to the leakage coefficient, its value will depend on the ratio of the magnetic resistance of the path offered to the lines of force *around* the armature, to that of the path offered *through* the armature. As long as the armature magnetization is not carried up to saturation, this ratio will be fairly constant. Of course, its value will vary somewhat for different types of field, depending on the paths offered for leakage, but as far as I have been able to discover, its value in single horse-shoe magnets varies very little from 1.3. It is possible to determine it very accurately from a theoretical investigation, but that is very tedious, and it may be more easily determined by trial on an actual machine. Once determined for one type of machine, it is good for all the sizes of that type, unless the saturation of the armature is very much changed.

I tested the accuracy of the curves which I obtained as a result of the experiments I made, by calculating the number of ampere-turns required by a number of machines ranging from ½ h. p. up to 80 h. p. and found that my results differed from the actual number required by less than 5 per cent. in all cases where the records were reliable.

Another characteristic of this method which I have not dwelt on is the clearness with which it shows forth the condition of affairs in the different parts of the circuit. Kapp's formula does not give the true resistance in any part of the magnetic circuit, and therefore, if formula and fact do not agree, there is no way of knowing just where to look for the cause of the discrepancy. The method described here gives the ampere-turns for each part of the circuit and makes it much easier to determine where to look for the disturbing element.

Below is given an example of the application of the method to the Edison-Hopkinson machine described in the London *Electrician* for 1886, page 39, and following. All the dimensions of the machine were first reduced to inches and are given below :

Edison-Hopkinson Machine.

Total number of lines through the armature, 10,850,000.
Coefficient of leakage, 1.32.
Total number of lines through the field, 14,322,000.

	Length.	Area.	Lines per sq. in.	Turns per in. in length	Total turns.
Armature......	10.1	125.6	86,500	31	318
Air Space.......	1.2	234	48,400	13,800	16,560
Limbs...........	.36	144	99,400	76	2,736
Yoke	19.35	174	82,300	25	484
Poles	4.4	191	75,000	19	84
Total...					20,177

Actual number of ampere turns, 19,560.

Percentage of calculated to actual, 103 per cent. That is, the calculated is 3 per cent. higher than the actual number found in practice.

The numbers in the third column are found by dividing the total number of lines traversing the part in question by its cross section. The fourth column is obtained from the third by means of the curves. The numbers in the fifth column are obtained by multiplying those in the fourth by the lengths of the magnetic circuits, and the total number of turns is the sum of all the numbers in the fifth column. I should like to give the figures on some of the machines by which I tested my curves, but the companies which kindly furnish me data, were unwilling to have those data published.

I do not propose at present to enter into all the applications of these curves, as they will readily present themselves, as, for instance, compounding and other methods of regulation.

In his last annual report on the Chicago City Railway, Mr. C. B. Holmes says that the operating expenses per horse car mile were 21.985 cents, and per cable car mile 9.650 cents. The company ran 12,740,480 cable car miles, and 4,859,200 horse car miles. The cost of repairs per car was $71.40. The company lost 1 in 20 of its horses by death.

ON A SIMPLE EXPERIMENTAL STORAGE BATTERY.

BY

Harry E. Dey.

I FIND that a great many so-called practical electricians are quite ignorant in regard to storage batteries and the principles upon which they are based. Most of them are anxious to learn, but have not the opportunity, and few books deal with the subject in a way to be understood, especially by those who have not had a technical education.

There is much to learn that can be taught only by experience, but I will endeavor to give the information derived from two and a half years of constant experimenting.

I should advise any one intending to experiment in this field, to commence by making a small Planté battery. It can be made at a cost of considerably less than one dollar, and will be found quite useful afterwards for any purpose where a constant E. M. F. is desired, or a heavy current needed for a short time. The one I am about to describe will quickly melt a No. 18 B. &'S. copper wire, and has a capacity of 3 ampere-hours, with an E. M. F. of 2 volts.

I shall begin by first explaining the principles on which the storage battery operates.

If a strip of platinum is attached to each of the two terminals of a battery and dipped into acidulated water, bubbles of gas will arise from each; oxygen coming from the positive, or that plate which is connected to the carbon, and hydrogen from the negative.

Now, if in place of platinum we use zinc, or any metal that will dissolve in the acid, the oxygen will combine with the zinc, and dissolve, forming sulphate of zinc. The hydrogen will escape, as in the first experiment, until enough zinc is dissolved to form a plating solution. The negative electrode then plates with zinc, and the hydrogen goes into the liquid to take the place of the zinc.

For a third experiment we will use two electrodes of sheet lead which will not dissolve in the acid. The oxygen enters into combination with the lead, and, as it is insoluble, does not leave the plate, but forms a thin coating of dark brown or black peroxide of lead on the surface. As the hydrogen has nothing with which to combine, it is given off freely in bubbles from the negative plate. After the positive plate is well coated with peroxide, reverse the direction of the charging current, and the negative (now positive) plate will become coated with peroxide and the hydrogen formed at the other plate will combine with the oxygen of the coating and form water, leaving the surface in a finely divided or spongy state. If tested now, it will be found to give a small current of electricity, having 2 volts E. M. F., but lasting only for a very short time. This can be greatly increased by charging and discharging many times, occasionally charging up in the reverse direction. In discharging, the finely-divided or spongy lead is attacked by the acid in the same manner as the zinc in a primary battery, of which it practically takes the place; the peroxide, which is one of the best of electro-negative elements, corresponding to the carbon or copper. A storage battery, when charged, is practically a primarybattery in its discharge action.

Now that we have the principles, let us endeavor to make a practical Planté battery. Out of a piece of $\frac{1}{16}$ (3 lbs. per foot) sheet lead cut 21 pieces, each 4 inches square, with a projecting end or lug for connection at one corner, ¾ of an inch in height, and ½ inch wide.

Procure 30 rubber bands one-eighth inch thick. If not convenient to obtain, they may be sliced from a piece of soft rubber hose containing no fibre. Place three of these on each of ten plates perpendicularly, one in the centre and one at each edge. These are to be the positive plates. Place all the plates together alternately, negative and positive, the bands separating them. Let the connections of one set be all on one side, and those of the other at the other side. Stretch a few bands around the plates, to clamp them together. Cut in a board, or mold in clay, two grooves ¾ inch wide, ½ deep, 8 inches long, and 2¼ inches apart, placing one four inches in advance of the other. Stand the plates on end, so that the lugs form feet standing in the grooves. Pour into the groove very hot lead to a depth of ¼ inch. They are now ready to place in the acid.

Take a jar containing about a quart of water, and pour in *very slowly*, stirring at the same time, two pounds of sulphuric acid, making it 1.2 specific gravity or 25° Beaume.

Place the plates in a suitable jar, and after the acid is cool, pour in enough to cover them. Connect the intended positive plates with the positive wire of a suitable charging current, remembering that the positive current from a primary battery comes from the carbon or copper plate, and the negative to the negative wire. The charging current should be nearly three volts; consequently it will require two bichromate of potash, or three gravity cells connected in series.

Charge and discharge often and occasionally reverse the charging current until it is found that the capacity does not increase. It will probably be about three ampere hours. See that the outside plates are negative with the final charge.

The plates may be formed much more quickly by first soaking in a fifty per cent. solution of nitric acid for twenty-four hours. In this case it is advisable to use thicker lead, five pounds not being too heavy. They can then be soaked nearly forty-eight hours. Rinse off before placing in the electrolyte. In another article I hope to treat of red lead batteries.

THE TORSION GALVANOMETER FOR PRACTICAL ELECTRICAL MEASUREMENTS.

BY

F. Uppenborn

IN the December 24 issue of THE ELECTRICAL ENGINEER there appears an article by Mr. Osborn P. Loomis on the application of the Weston voltmeter to the measurement of resistances. I would like to call attention to the fact that the torsion galvanometer of Siemens & Halske is better adapted to this class of measurements than the Weston voltmeter. All electrical measurements which are met with in the practice of electrical engineering may be carried out in the most exact manner with the torsion galvanometer.

The application of the latter to the measurement of insulation resistances was proposed by me as early as 1888 in the *Centralblatt für Elektrotechnik.* In this methods insulation resistances from a short circuit up to 100,000 ohms can be measured, according to the difference of potential employed. Very small resistance can also be determined with the aid of this instrument. It will also measure differences of potential from .001 up to 1,700 volts; currents from .001 up to 100 amperes, and more.

According to my judgment the torsion galvanometer is the most convenient and accurate measuring instrument which can be used in practice. I could never conceive why the instrument should be so little used abroad, and that many writers on electrical subjects treat of it in a very off-hand manner, or do not mention it at all. I would refer those interested in the application of the torsion galvanometer, for the measuring of resistances to an article appearing in the *Centralblatt für Elektrotechnik*, vol. x, p. 585.

NEW BRITAIN, CONN.—The New Britain Electric Light Co., at its adjourned annual meeting, voted to increase its capital stock from $60,000 to $80,000, the present stockholders to get the preference on the new stock.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—XIII.

(*Copyright, The Electrical Engineer.*)

BY

Herbert Laws Webb

TEST FOR CAPACITY.

Fig. 33 shows the connections for taking the discharge of the cable. The cable is connected to the lever of the discharge key, the other connections remaining the same, with the exception that here the second pole of the battery and the second terminal of the galvanometer must necessarily be connected to the earth.

It is usual to charge the cable for 15 seconds by pressing the lever down on the lower contact and keeping it clamped there by means of the trigger, for that time. The trigger is then pulled back, releasing the lever and allowing it to fly up to the upper contact, thereby discharging the cable through the galvanometer to earth.

We will assume that the inductive capacity of a cable half a mile long is to be measured. By means of the plugs a section of .1 microfarad of the condenser is connected to the terminal blocks and the discharge taken with five cells of battery in the manner described. The deflection is 200 divisions of the scale. The cable is connected to the discharge key, and a discharge taken in the same manner. A deflection of 175 divisions is obtained. Now, the deflection of 200 was given by the discharge of a condenser of known capacity; therefore, if we divide the second deflection by the first we shall obtain the capacity of the cable in terms of the capacity of the condenser:

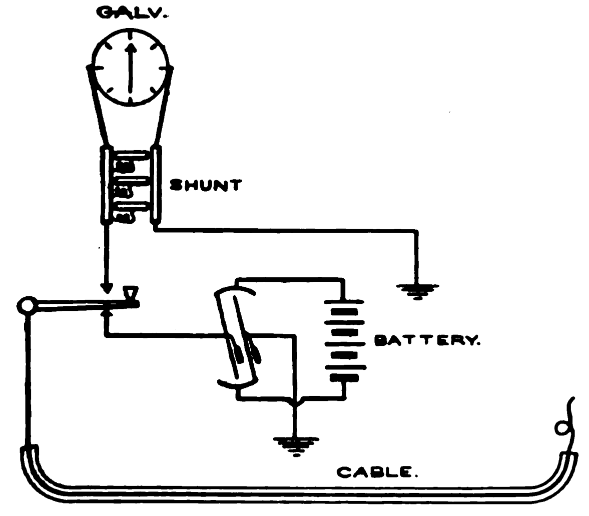

FIG. 33.—CAPACITY TEST, CONNECTIONS FOR CABLE DISCHARGE.

$$\frac{175}{200} = .875.$$

Therefore the capacity of the cable is .875 of the capacity of the condenser. The capacity of the condenser, however, was only .1 of a microfarad; therefore, to obtain the absolute capacity of the cable in microfarads we must multiply the above result by .1:

$$.875 \times .1 = .0875.$$

The absolute capacity of the cable then is .0875 microfarad.

We always need to reduce our results to a definite unit of length and of course need to know the capacity per mile. We have already seen that the insulation resistance decreases with the length of the cable and that the absolute insulation must be multiplied by the length in order to arrive at the insulation per mile. With inductive capacity the reverse is, of course, the case, the capacity of a cable increasing with its length. This is obvious, if we consider a cable as a form of condenser. One mile of a cable has a certain capacity, then two miles of the same cable will have twice the capacity, five miles five times the capacity and so on. Therefore, to determine the capacity per mile, the absolute capacity must be divided by the length. In this case the absolute capacity is .0875 microfarad and the length .5 mile.

$$\frac{.0875}{.5} = .175.$$

Therefore, the inductive capacity per mile of the cable being measured, is .175 microfarad.

The discharge from the condenser is often called the capacity constant, just as the constant of the galvanometer is often called the insulation constant. Neither expression is correct, but if they are used it should always be remembered that in working out a test for capacity the operations performed in working out the insulation are exactly reversed. For insulation, the constant is divided by the cable deflection to obtain the absolute, and, to obtain the insulation per mile, the absolute is multiplied by the length. For capacity the cable deflection is divided by the "constant" to obtain the absolute capacity, and to arrive at the capacity per mile, the absolute is divided by the length.

It must always be borne in mind that in dividing the discharge of the cable by the discharge of the condenser the result obtained is in terms of the capacity of the condenser employed. If a condenser of 1 microfarad capacity is used, the result will be in microfarads, but if the capacity of the condenser is $\frac{1}{3}$, $\frac{1}{10}$ or $\frac{1}{20}$ of a microfarad the result must be divided by 3, 10, or 20, as the case may be, in order to determine the capacity of the wire or cable in microfarads. Supposing a condenser of $\frac{1}{3}$ microfarad were used and gave a discharge of 120, and the cable gave a discharge of 150; then the capacity of the cable would be

$$\frac{150}{120} + 3 = .4166 \text{ microfarads.}$$

If the cable were 1.5 mile long, then the capacity per mile would be

$$\frac{.4166}{1.5} = .277 \text{ microfarad.}$$

If we were to use a condenser of .05 microfarad capacity, and obtained a discharge of 75, and from the cable one of 100, then the absolute capacity of the cable would be

$$\frac{100}{75} + 20 = .0666.$$

Supposing the cable to be 2,165 ft. long, or .41 of a mile; then the capacity per mile would be

$$\frac{.0666}{.41} = .1624 \text{ microfarad.}$$

When a number of wires are to be tested for capacity it is best to multiply the discharge from the condenser by the quotient of the value of the condenser, divided into one, which will give the discharge that would be obtained from a condenser of one microfarad capacity. Then dividing the discharges of the wires by this figure will give the absolute capacities directly in fractions of a microfarad.

If the condenser is adjusted to a capacity of .05 microfarad and gives a discharge of 75, by multiplying this discharge by 20, $\left(\frac{1}{.05}\right)$, we obtain 1,500, which is the discharge that a condenser of 1 microfarad would give with the same conditions of battery-power and galvanometer. Then by dividing the discharge deflections of the wires by 1,500 we obtain their capacities in fractions of a microfarad. This will be found more quickly than dividing in each case by the condenser discharge, and again by the capacity of the condenser.

EDITORIAL ANNOUNCEMENTS

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XI. NEW YORK, FEBRUARY 11, 1891. No. 145

Matter is indestructible, and is measured by weight; energy is indestructible, and is measured by work; intelligence is indestructible and is measured by adaptation.—Josiah Parsons Cooke.

ELECTRIC RAPID TRANSIT FOR NEW YORK.

THE ease with which the Rapid Transit bill was passed by the Legislature of this State was a striking exemplification of the degree to which the importance of the question has been realized. Over any ordinary measure, there would have been the usual amount of delay from one cause or another, and nobody would have been held particularly to blame. But in this case, the needs of the city and the people were so apparent that to trifle with them became dangerous work, and no politician cares to run counter to the popular will for a very long time after he has satisfied himself as to what the popular will is. Now if there is one thing upon which the public resolve is set, it is to get better transportation between the heart of the city and the suburbs. The movement is largely based upon the individual desire for greater speed and convenience in travel, but it affects larger issues, and touches the very welfare of the State as well as the future position and prosperity of this great city of New York.

The Rapid Transit law is broad and liberal, and under its provisions the Rapid Transit Commissioners should be able to confer great boons on the community. It permits the extension, as we understand it, of present facilities, and there is no good reason why concessions should not be made to the Elevated Railroad such as will tend to the advantage of the passengers over it. But the chief concern, of course, is with the new facilities to be created, and it is here that the electrical engineer perceives his legitimate opportunity. With electric traction in its present advanced state, handling a business in this country of 500,000,000 passengers per year, he knows that the resources of his art are equal to every demand or strain that the very best system of rapid transit can put upon them. The success of the underground electric road in London, which is already working to its full capacity and is to be greatly developed and extended, shows that here in New York, if we will, we can leave all the old methods behind at one stride, and secure the ends after which the city has yearned in vain these fifty years.

THE STORAGE BATTERY IN TELEGRAPH AND TELEPHONE WORK.

ALTHOUGH the primary battery in the shape, principally, of the gravity and other forms of the Daniell cell still holds its own as the source of current for the operation of telegraphs, signs are not wanting to indicate that for the larger telegraph offices at least the days of the battery are numbered. It is now more than fifteen years ago that the Western Union Company introduced the dynamo to operate a large number of its circuits centering in this city, and of late it has extended this practice by similar installations in Albany, Pittsburgh and Chicago. The reduction in the number of cells effected by this change amounts, as may be readily calculated, to many thousands, involving not only a large saving in room, but also in expense of maintenance. In contrast to this it is interesting to note that, abroad, the use of the storage battery seems to be looked upon with more favor in this class of work than the application of the dynamo direct. The success here attained with the latter goes to indicate that so far as steadiness of current is concerned little is left to be desired in any respect, and the foreign arrrngement with storage batteries may be looked upon as the outcome of a more conservative, not to say timid, management. Thus far we believe no instance is on record in which the source of current from dynamos has failed in this country, especially as all the arrangements are in duplicate to guard against break-downs; and it will be recalled that during the recent fire in the Western Union Building, notwithstanding the total destruction of all the batteries, the dynamos were maintained in continuous operation throughout, thus affording the company an incalculable benefit. In the arrangements adopted in Berlin, which we describe in this issue, the storage battery is evidently doing excellent work, and its use will without doubt be extended there. As our readers may be aware, storage batteries have been in use for some time in the General Post Office in London, their use having been early advocated by Mr. William H. Preece. The low internal resistance of the cells makes them admirably adapted for operating a large number of circuits and for this reason they are peculiarly suited to telephone work where transmitters are placed in multiple. As an example of this our readers will note such an application in the operation of the long distance concerts, a very interesting example of which we describe on another page. In these transmissions very powerful transmitters are employed, which take a current far in excess of that usually employed on short line work and in which the cells are drawn upon to a considerable extent for current.

PRACTICAL TESTING INSTRUMENTS.

The excellent article by Mr. Osborn P. Loomis, published in a recent issue of The Electrical Engineer, describing the application of the Weston voltmeter to a variety of tests, has called forth a communication from a well-known German electrical engineer, Mr. F. Uppenborn, in which he draws attention to the merits of the torsion galvanometer for practical methods of electrical measurement. While there can be no doubt as to the wider range and sensitiveness of the torsion galvanometer over any type of instrument based on the principle of the Weston voltmeter, it cannot be denied that for many purposes the latter has advantages which the torsion galvanometer does not possess. Principal among these is the great portability of the Weston voltmeter, and the fact that it can be used practically in any position. If to this is added the fact that its sensitiveness is also far greater than that of any similar instrument yet devised, it must be admitted that it occupies a position which it would be difficult to fill by an instrument of the type of the torsion galvanomter, which must be set up in a fixed position, is subject to disturbances by vibration, and requires manipulation in order to obtain the desired reading. In estimating the value of a practical instrument, the qualities of portability and direct reading cannot be overestimated, and when these are taken into consideration the Weston voltmeter must be admitted to occupy a field to a large extent distinct from that to which the torsion galvanometer is applicable.

THE ERNST STORAGE BATTERY.

The ills to which the storage battery is subject may be said to be largely, if not entirely, due to the chemical changes which the active material undergoes during charge and discharge, and which are followed by mechanical changes. Thus it is well known that plates grow during use, and where the arrangement is not such that a certain flexibility is provided for, buckling and other distortions take place. An interesting departure in the construction of such cells is that due to Mr. V. H. Ernst, which we describe elsewhere in this issue, and in which provision has been made for the changes in volume which the active material undergoes. This has been very ingeniously effected by providing the active material with a flexible core which shall at the same time provide a means of affording the solution access to the interior parts of the active material. In the experiments recently made by Prof. Ayrton and his associates, and described in our columns, it was shown that a considerable percentage of the active material in the present form of storage battery remained inactive. It would therefore be interesting to know to what extent an intercirculatory system, such as that of Mr. Ernst, would overcome this difficulty, and we hope a test to determine this point may be made at an early date.

The Electrical Industry Considered Geographically.

One of the most interesting publications that has reached our hands lately is an atlas issued by the Thomson-Houston Company, showing, State by State, the distribution of the various electric lighting and electric railway systems. The work has been about as well done as it could be, and presents may suggestive points for note and study. The Thomson-Houston Company itself has no reason to be ashamed of the exhibit made. Out of a total of 1,985 central station plants of all systems, it has 666, or more than twice as many as its nearest competitor; and out of 240 electric railways it has 103. If to these preponderating figures we add those of its allied and subsidiary systems, it would have a good half in each field of work. It would have been interesting to have with these statistics a financial exhibit of the value of investment that each system represents, as a mere total of plants must necessarily include single stations that weigh against at least a hundred others; but even under this head, the publishers could doubtless hold their own most satisfactorily. As to the general showing of the industry, it may be said that the introduction of electric lights and electric railways is evidently very widespread.

World's Fair—Appointment of Mr. Barrett.

Official announcement is made of the appointment of Mr. John P. Barrett as Chief of the Electrical Department of the Columbian Exhibition. This selection by Director General Davis and the board ensures a vigorous and comprehensive treatment of the electrical part of the industrial exhibit, and a thorough-going execution of the plans adopted for that important part of the World's Fair. Mr. Barrett's energy of character and executive capacity are well known in electrical circles, particularly so in the West, where he has for many years been in charge of the Electric Bureau of the city of Chicago. With the services of an adequate engineering and technical staff, yet to be appointed, Mr. Barrett may be expected to organize and exhibit in 1893 such a display of the arts of electricity as has never been seen before, including a hitherto unexampled employment of electrical means of illumination transmission of power, communication and transit throughout the various grounds and edifices of the fair.

Reminiscent.

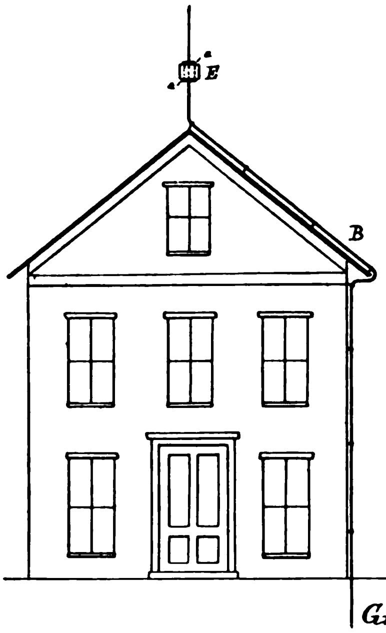
The present generation of telegraphers can scarcely recall a time when, as has been the case during the recent breakdown of communication, messages between New York and Philadelphia have, in default of wires, been sent by train for three or four consecutive days. In the old days such occurrences were not so infrequent as to excite especial comment. In one respect, at least, the modern customs are some small improvement over those which formerly obtained, inasmuch as messages are now accepted, as the receiving clerk suavely informs the customer, "subject to indefinite delay," whereas in ancient days, it might in most instances have been affirmed with entire truth, that the message and the customer were "taken in" simultaneously, for the urbane clerk would never have dreamed of "giving it away" even if the line had been helplessly down for a fortnight. The muse of the immortal Selden once ventured to touch lightly upon this theme; his reflections, as we remember them, ran somewhat thus:—

> Little that indulgent public
>   Guess how they are skinned alive,
> We know better how it's managed;
>   "Package by express at five."

NEW METHOD OF PROTECTING BUILDINGS FROM LIGHTNING.

Heretofore, protection from the destructive effects of lightning has been sought by the use of a metallic conducting rod, which is expected to take up, constantly, whatever excess of electricity there may be in the surrounding atmosphere, whether diffused, or in the form popularly known as a "bolt," and carry it to the earth, where it would be harmlessly dissipated. This method has, in many cases, proved wholly inadequate, buildings so protected having been damaged by lightning.

The accompanying illustration represents a novel type of lightning arrester devised by Mr. Nathaniel D. C. Hodges, in which he makes use of the well-known fact, that the potential of any given quantity of electricity, is dependent upon the surface of the body over which it is forced to spread itself. Thus a given quantity of material in the form of a solid mass, when charged nearly to repletion, will exhibit a very high electromotive force; while, according to Mr. Hodges, if the amount of electricity, and the quantity of material remain the same, but the structure of the material be changed from a solid to a scattered, fine powder or vapor, the potential of the electricity there stored practically disappears.



Hodges' System of Lightning Protection.

The object of Mr. Hodges' invention, therefore, is to take advantage of this property of extended surface present in pulverized substances, and thus, without attempting to lead the electricity away from the threatened building, to place such a substance in the probable path of the current in such manner that the electricity will pass into this substance in preference to attacking the threatened building. In charging this interposed substance, providing the aggregate surface of its parts is sufficiently large, Mr. Hodges claims that the potential of the most violent "bolt" of lightning becomes destroyed, or so greatly reduced that the current will readily be carried off by the rod, or even dissipate itself harmlessly in the surrounding moist air.

In the illustration the box E containing the soot is of thin, non-conducting material, and is interposed in the lightning-rod, B, about six or eight feet above the roof of the building, the rod being broken at that point and connected by means of the fine wires, *a*, so that the electricity can pass from that portion which enters the top of the box, to that which emerges from the bottom, only by passing through the soot. According to Mr. Hodges, as soon as the electricity enters a substance of this structure, its particles fly apart, some or all of them being charged, and thus the potential will be greatly reduced and probably no further harm will result. This effect, of course, would depend largely upon the quantity of soot employed; but a cubic foot, Mr. Hodges asserts, would probably be found sufficient for all ordinary cases.

SPECIFICATIONS FOR WIRING WITH THE "INTERIOR CONDUIT" SYSTEM.

We print below the standard specification form adopted by the Interior Conduit and Insulation Co., for electric light work:—

System.—The building to be thoroughly equipped from the source of supply to each outlet with the insulating conduits of the Interior Conduit and Insulation Co. in such manner as to provide continuous channels or race-ways for the wires. The continuity of each tube employed for this purpose shall be such as would be required if it were to be used for conveying water or gas.

Strict compliance with this requirement will be demanded, since one of the chief advantages of the system, herein specified, is to exclude water and gas from the wires, and therefore afford adequate protection against their deleterious effects.

Accessibility.—To the end that each and every wire may be at all times accessible for inspection, repairs or renewal, the location, sectional division, joining, intermediate and terminal elbowing, the placing of switches, cut-outs and junction boxes and the final emergence of the tube beyond the finished surface at the fixture outlet, must be done in strict compliance with the rules and regulations herein contained.

Appliances.—In order to secure safety, durability and convenience and to give a finished character to the work, all appliances employed shall be such as are designed especially for use in conjunction with this system.

Subdivision of Risers.—The building must be divided into a number of sections, and each section provided with an independent group of risers, thus avoiding the multiplication of elbows, intersection boxes and long runs of the taps or branches. Every conductor in each group of risers must be provided with an independent tube.

Branches.—For all branches the standard "twin conductor" of the Interior Conduit and Insulation Co., requiring but one tube, must be employed. The current limit of the branches must be that fixed by the Fire Underwriters' rules.

Size of Tubes.—All tubes must be of sufficient size to allow the wires to be readily drawn in, withdrawn and reinserted at will. A quarter (¼) inch tube will be permitted only where space is extremely limited, as under a thin plaster finish.

Clips.—Tubes, whether concealed or on the surface, must be held in place by metal "clips;" the use of staples for such purpose will not be allowed where it can be avoided.

Joints.—The tubes must be cut squarely and then reamed out smoothly and the ends joined in the manner and by the use of the corrugated coupling designed for that purpose.

Elbow Limitations.—Where more than four elbows are unavoidable, an intersection box must be inserted to relieve both the wires and the tubes of strain when the wires are being drawn in.

Outlets.—All tubes must emerge at outlets in terminal boxes, thus leaving the outlets so protected as not to be injured by the plasterers.

Fixture Supports.—Where no gas pipe or other support for the fixtures exists, the special form of terminal box designed to furnish such support must be employed, and must be substantially fixed to a suitable foundation in the ceiling or walls.

Junction Boxes.—Main circuit junction boxes, must be placed on each floor in each section; from these junction boxes all branches in that section must ramify.

Cut-Outs.—Standard non-combustible cut-outs must be used within the junction boxes, and each branch wire leading from the same must be protected by a safety fuse.

Floor Work.—To guard against mechanical injury and the destructive action of cement, all floor conduits must be made of double tube, one telescoped within the other and both the outer and inner tubes joined in the usual manner. The outer tube must, in the case of contact with cement, be alkali proof. As a further protection, all floor tubes must be covered during construction with a light board.

Wires.—For mains a conductor having an insulation known as "fire and weatherproof" and for branches the standard twin conductor of the Interior Conduit and Insulation Co. must be used.

Annunciator Wiring.—All annunciator or bell wires must be placed within conduits and such of the foregoing rules and regulations as are applicable to rendering them accessible and affording suitable protection shall be followed.

Inserting Wires.—After the conduiting is completed powdered soapstone must be blown into the tubes in order to facilitate the drawing in of the wires.

Inspection and Acceptance.—As a guarantee that the wiring will be properly done, it is required that the contractors, in event of their being unfamiliar with the system, communicate with the Interior Conduit and Insulation Co., of New York, or their authorized representatives, and obtain the requisite instruction. The right is reserved to subject the work of the contractor to the inspection and approval of the Interior Conduit and Insulation Co. as a condition of acceptance and final payment.

ON THE ALTERNATING ELECTRIC ARC BETWEEN A BALL AND POINT.[1]

BY EDWARD L. NICHOLS.

THE phenomenon which forms the subject of this paper, was first brought to my notice by Mr. E. G. Acheson, the result of whose unpublished observation, may be briefly stated as follows:

Two wires, which formed the terminals of the secondary coil of an alternating current transformer, were brought nearly into contact. One wire was armed with a ball, the other with a point. When the distance was such as to admit of a discharge between the two, it was found that a galvanometer in shunt around the ball and point, indicated a considerable flow of continuous current.

This phenomenon has recently been subjected to investigation by Messrs. Archbold and Teeple. Their experiments, from which in great measure, the data used in the first part of this paper have been taken, are described at length in their Thesis in Electrical Engineering, which is now in the library of Cornell University.[2]

The apparatus used in the verification of Mr. Acheson's observation, consisted of a Ruhmkorff coil of moderate size, the interrupter and condenser of which had been thrown out of circuit. The primary coil, as in all instruments of that type, consisted of a few turns of heavy wire, surrounding a core of iron wires. When this coil was supplied with current from a small alternating dynamo, making 14,000 reversals a minute, and the terminals of the secondary coil were brought into position, a discharge of considerable brilliancy took place between them. To the unaided eye, the discharge appeared to be perfectly continuous, but the fact that it was really of an intermittent and periodic character, was indicated by the emission of a well defined musical note, which corresponded in frequency with the period of alternation of the dynamo.

The following quotation will serve to indicate the conclusions reached by the observers in the course of their preliminary experiments with the platinum point:

"The behavior of the arc, as its length is increased, is very curious. As the point is withdrawn the arc forms and sings with an even tone, the pitch corresponding to the number of alternations. The point becomes of a dull red color while the galvanometer gives a small but quite steady deflection. As the arc is drawn out, it sings louder and more harshly, the point becomes redder, while the galvanometer deflection increases and becomes very unsteady. At a certain critical length the following phenomena suddenly occur; the tone becomes smooth and even, the point brightens almost to a white heat, the intensity depending upon the strength of the current, while the galvanometer deflection becomes much greater and very steady. The explanation suggested, and which subsequent experiments seem to confirm, is as follows: At first the arc forms both ways, the rapid succession giving the tone. As the arc lengthens the arc still forms from ball to point, but is only intermittent (occasional) from point to ball, giving the unsteady tone and deflection. Finally the distance becomes too great for the arc to form from the point to the ball while it still passes freely the other way, and the tone and deflection become steady."

It was to the conditions existing in the circuit when the critical length of the arc, above mentioned, had been reached, that Messrs. Archbold and Teeple chiefly devoted themselves.

The main portion of the investigation consisted in the determination of the periodic changes of electromotive force and current during a complete cycle, when no arc existed, and of the modifications introduced into the curves of potential and current by the discharge between ball and point. Throughout the entire series of measurements, the striking distance was greater than the critical value already defined, a condition the maintenance of which was secured by watching the indications of the galvanometer.

The ball and point phenomenon is unquestionably very closely related to a class of effects with which students of static electricity have long been acquainted.

In view of the experiments described in the present paper, it appears that what is true in this particular of the spark from the Leyden jar and the discharge of the Holtz machine, is true also of the alternating current arc.

After the completion of the experiments of Messrs. Archbold and Teeple, the study of the ball and point phenomenon was taken up under the writer's direction by Mr. F. C. Caldwell; the chief purpose of the investigation being to test the applicability of the effect to alternate current measurement.[3]

Irregularities of action due to rapid changes in the surfaces of the point and ball, by corrosion and disintegration under the arc, finally caused the attempt to be abandoned for the time being, but Mr. Caldwell in the course of his work made a large number of observations of the discharge under various conditions. Many of these are of interest in this connection on account of the light which they throw upon the original experiments, and because of the lines of further research which they suggest.

From these observations it appears:

1. That the discharge from the ball (positive) leaves the latter in a direction normal to the surface, but that it enters the other terminal at some distance from the apex.

2. That the discharge from the point (positive) leaves the very apex of the latter, but is deflected into a course nearly 45° from the axis and reaches the ball obliquely at some point on its side.

Taking these observations into consideration, the explanation of the cessation of the discharge from the point at the critical distance and of the establishment of the "one way" arc, follows at once. The two paths of discharge differ in length and for a given electromotive force, the maximum striking distance is sooner reached in the case of the oblique than of the normal arc, so that the latter continues to pass at greater distances (of ball and point) than the former.

Definite results were obtained only while the platinum surface was new and bright.

In this brief account of Mr. Caldwell's experiments, I have omitted to mention many of the observations recorded by him. He had occasion in the course of his investigation, to study the discharge under a variety of conditions, and found that when liquid surfaces (mercury or water) were used in place of the ball; also that when hydrogen, carbon-dioxide or illuminating gas were substituted for air, as a dielectric, the ball and point effect, more or less modified, could still be obtained. The investigation of these points, although it has already led to some results of significance, is as yet very incomplete.

PHYSICAL LABORATORY OF CORNELL UNIVERSITY: Sept., 1890.

THE DIFFERENCE OF POTENTIAL BETWEEN TWO DILUTE SOLUTIONS OF BINARY ELECTROLYTES.

THE development of electricity and heat in electrolytes has been the subject of much investigation during the past few months by M. Planek, who has contributed several papers to Gilbert's *Annalen der Physik und Chemie*. In one of these papers (*vide* Series [2], Vol. xxxix., p. 161) he argued that since the ions of an electrolyte are endowed with large electrostatic charges, it follows that before the electromotive forces become active a certain finite determinable amount of free electricity must be formed in the solution. The forces necessary to cause a movement of electricity in an electrolyte are referred to in this paper, starting with the assumption that in an electrolyte the ions are present in a fully dissociated condition.

Planek now considers (*vide Annalen Phys. Chem.*, Series [2], Vol. xl., p. 561) the integration of the differential equations for the general case of two solutions containing different electrolytes, having already calculated the difference of potential for the case of two solutions containing the same electrolyte in different proportions.

The existence between the two solutions of a limiting layer of small but still finite thickness is assumed. Different values for the difference of potential are found according to the way in which the concentration is supposed to alter within the intermediate layer. Planek shows, however, that in a very short time a state of stability will be reached in which the total concentration (sum of the concentrations of the positive or negative ions) will vary within the layer as a linear function of the distance. This consideration is sufficient to make the above problem uniquely soluble, supposing the electrolytes to be completely dissociated. Planek compares the calculated values for the difference of potential with Nernot's experimental numbers, with which they show a satisfactory agreement.

ELECTRIC LIGHT STATIONS RUNNING ELECTRIC ROADS.

There is a tendency in many towns either to consolidate the electric light and electric railway interests or furnish power to the road from the electric light station. Among the companies adopting the latter practice is the Zanesville Electric Light Co., which has made a contract for ten years with the Zanesville Street Railway Co. for furnishing motive power for its electric road.

ELECTRICITY IN TRANSITU: FROM PLENUM TO VACUUM.

BY WM. CROOKES, F. R. S.

(*Continued.*)

EXPLORATION WITH IDLE POLES.

Wishing to learn something of the electrical condition of the matter within and without the dark space, I made a tube, Fig. 7, having, besides the positive and negative terminals, A B, two extra intermediate poles, C and D; the tube showed that when the exhaustion was such that both the idle poles were outside the dark space, on passing the current through the tube, there was a considerable difference of potential between them when measured on the galvanometer. If the exhaustion was carried so high that one of the extra poles was just on the border of the dark space, then no current passed between them. When the exhaustion was still further increased so as to enclose one of the extra poles fully in the dark space, again there was a great difference of potential between them, but the direction was reversed, the pole at highest potential now being the one formerly at lowest potential.

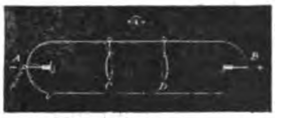

FIG. 7.—P = 75 mm.

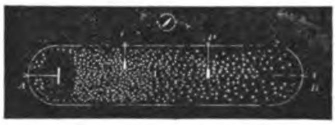

FIG. 8A.—P = 0.25 mm. = 330.0 M.

When the dark space has been further explored by means of a movable negative pole, I found that the effects did not depend essentially on the exhaustion, and were really due to the position occupied by the extra poles with regard to the dark space.

These phenomena are difficult to understand from mere description, and the experiments themselves are not easy to carry out so as to be visible to many at a time. I have here, however, a working model of an apparatus which will make these puzzling indications clear to all.

A cylindrical tube, Fig. 8, *a*, *b* and *c* (P.=0.25 mm.), furnished with the usual poles, A B, at the ends, has two extra or idle poles near together at C and D. The pole A is movable along the axis of the tube, so that when exhausted the dark space can be brought to any desired position with respect to the idle poles C and D. The shading and + and — marks roughly show the distribution of positive and negative electricity inside the tube. I start with the negative pole, A, as far as possible from either idle pole, Fig. 8*a*. Turning on the coil you see the dark space surrounding the pole A, and the idle poles quite outside.

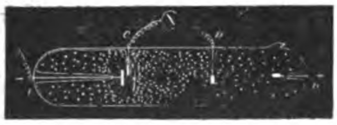

FIG. 8B.—P = 0.25 mm. = 330.0 M.

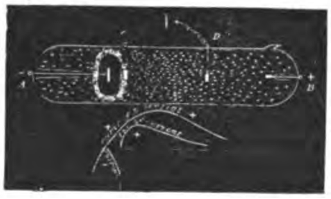

FIG. 8 C.—P = 0.25 mm. = 330.0 M.

The shading shows that each idle pole is in the positive area, and on testing with a gold leaf electroscope it will be seen that each is charged with positive electricity. But the shading also shows more positive at C than at D and on connecting C and D with a galvanometer the needle indicates a rush of current from C to D, D being negative to C.

The dark space is next brought to such a position that the pole C is well within it, Fig. 8*b*. A change has now come over the indications. The galvanometer shows a reverse current to that which was seen on the former occasion. C is now negative and D positive, but the gold leaves still tell us both poles are positively electrified.

At a certain position of the dark space, when its edge is on the pole C, Fig. 8*c*, a neutral state is found at which the gold leaves still show strongly positive electrifications, and no current is seen on the galvanometer. The curves below, Fig. 8*c*, roughly show the rise and fall of negative and positive current at different parts of the tube, whilst the potential curve keeps positive.

When a substance that will phosphoresce under electrical excitement is introduced into the tube, the position of greatest luminosity is found to be at the border of the dark space, just where the two opposing armies of negative and positive atoms meet in battle array and recombine. Later on I shall refer to this phenomenon in connection with the phosphorescence of yttria.

RADIANT MATTER.

By means of this tube, Fig. 9, I am able to show that a stream of ultra-gaseous particles, or radiant matter, does not carry a current of electricity, but consists of a succession of negatively electrified molecules whose electrostatic repulsion overbalances their electromagnetic attraction, probably because their speed along the tube is less than the velocity of light. The tube has two negative terminals, A A′, close together at one end, enabling me to send along the tube two parallel streams of radiant matter, rendered visible by impinging them through holes in a mica diaphragm on a screen of phosphorescent substance. It is exhausted to a pressure of 0.1 mm. I connect one of the negative poles, A, with the induction coil and the luminous stream darts along the tube from C to D parallel with the axis. I now connect the other negative pole, giving a second parallel stream of radiant matter. If these streams are in the nature of wires carrying a current they will attract each other, but if they are simply two streams of electrified molecules they will repel each other. As soon as the second stream is started you see the first stream jump away in the direction C E, showing strong repulsion, proving that they do not act like current carriers, but merely like similarly electrified bodies. It is, however, probable that were the velocity of the streams of molecules greater than that of light, they would behave differently and attract each other, like conductors carrying a current.

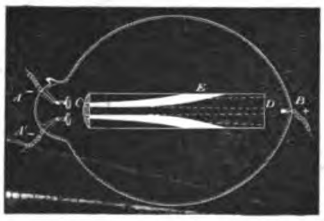

FIG. 9.—P = 0.1 mm. = 131.5 M.

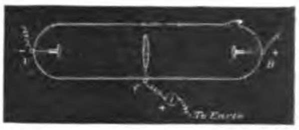

FIG. 10.—P = 0.0001 mm. = 0.13 M.

To ascertain the electrical state of the residual molecules in a highly-exhausted tube such as you have just seen, I introduced an idle pole or exploring electrode between the positive and negative electrodes in such a manner that the molecular stream might play upon it. The intention was to ascertain whether the molecules on collision with an obstacle gave off any of their electrical charge. In this experiment, Fig. 10 (P. = 0.0001 mm., or 0.13 M[1]), it was found that an idle pole, C, placed in the direct line between the positive and the negative poles, A B, receiving in consequence the full impact of the molecules shot from the negative pole, manifested a strong *positive* charge.

THE EDISON EFFECT.

An exactly parallel experiment has been made by Mr. Edison, Mr. Preece, F. R. S., and Professor Fleming, using, instead of a vacuum tube, an incandescent lamp. They found that from an idle pole placed between the ends of the filament the electricity always flowed as if the pole were the zinc element of a copper-zinc cell; having repeated their experiments I entirely corroborate them. I get a powerful current in one direction from an idle pole placed between the limbs of an incandescent carbon filament and one in the opposite direction from an idle pole in a highly-exhausted vacuum tube. This discrepancy was extremely puzzling, and I tested, with a similar result, very many experimental tubes made in different ways. The electricity obtained from an idle pole placed between the positive and negative terminals in a highly-exhausted tube was always strongly *positive*, and it is only recently that continued experiment has cleared the matter up.

Some of the contradictory results are due to the exhaustion not being identical in all cases. In my vacuum tubes the directions of current between the idle pole and the earth changes from negative to positive as the exhaustion rises higher. Testing the current when exhaustion is proceeding, there is a point reached when the galvanometer deflection—hitherto negative—becomes nil, showing that the potential at this point is zero. At this stage, the passage of a few more drops of mercury down the pump tube renders the current positive. This change occurs at a pressure of about 2 mm.

AFTER this point is reached, when the induction current is passed through the tube, the walls rapidly become positively electrified, probably by the friction of the molecular stream against the glass, and this electrification extends over the surface of any object placed inside the tube. I will show you how this electrification of the inner walls of the tube acts on the molecular stream at high vacua. In this tube, Fig. 11 (P. = 0.001 mm. or 1.3 M.) are fixed to exactly similar phosphorescent screens, C and D; at one end of each is a mica gate, E E', with a negative pole, A A', facing it. One of the screens, C, is in the cylindrical part of the tube and close to the walls; the other, D, is in the spherical portion, and therefore far removed from the walls. On passing the current the screen D in the globe shows a narrow sharp streak of phosphorescence, proving that here the molecules are free to follow their normal course straight from the negative pole. In the cylindrical part of the tube, however, so great is the attraction of the walls that the molecular stream is widened out sufficiently to make the whole surface of the screen C glow with phosphorescent light.

---

[1] M. = one-millionth of an atmosphere. 1,000,000 M. = 760 mm. 1,000,000 M. = one atmosphere.

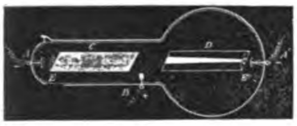

FIG. 11.—P = 0.001 mm. = 1.3 M.

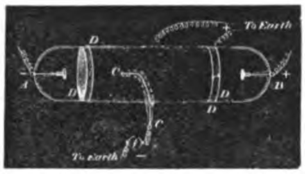

FIG. 12.—P = 0.0001 mm. = 0.13 M.

If an idle pole, C C, Fig. 12 (P. = 0.0001 mm. or 0.13 M.), protected all but the point by a thick coating of glass, is brought into the centre of the molecular stream in front of the negative pole, A, and the whole of the inside and outside of the tube walls are coated with metal, D D, and "earthed," so as to carry away the positive electricity as rapidly as possible, then it is seen that the molecules leaving the negative pole and striking upon the idle pole C on their journey along the tube carry a negative charge, and communicate negative electricity to the idle pole.

This tube is of interest since it is the one in which I was first able to perceive how in my earlier results I always obtained a positive charge from an idle pole placed in the direct stream from the negative pole. Having got so far, it was easy to devise a form of apparatus that completely verified the theory, and at the same time threw considerably more light upon the subject. Fig. 13, *a*, *b*, *c*, is such a tube, and in this model I have endeavored to show the electrical state of it at a high vacuum by marking a number of + and — signs. The exhaustion has been carried to 0.0001 mm., or 0.13 M., and you see that in the neighborhood of the positive pole, and extending almost to the negative, the tube is strongly electrified with positive electricity, the negative atoms shooting out from the negative pole in a rapidly-diminishing cone. If an idle pole is placed in the position shown at Fig. 13, *a*, the impact of positive and negative molecules are about equal, and no decided current will pass from it, through the galvanomer, to earth. This is the *neutral* point. But if we imagine the idle pole to be as at Fig. 13, *b*, then the positively electrified molecules greatly preponderate over the negative molecules, and positive electricity is shown. If the idle pole is now shifted as shown at Fig. 13, *c*, the negative molecules preponderate, and the pole will give negative electricity.

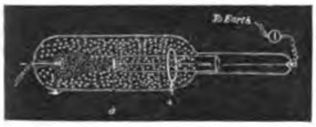

FIG. 13 A.—P = 0.0001 mm. = 0.13 M.

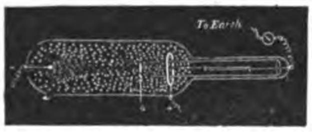

FIG. 13 B.—P = 0.0001 mm. = 0.13 M.

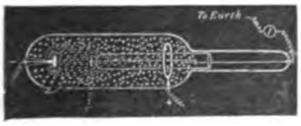

FIG. 13 C.—P = 0.0001 mm. = 0.13 M.

As the exhaustion proceeds, the positive charge in the tube increases, and the neutral point approaches closer to the negative pole, and at a point just short of non-conduction so greatly does the positive electrification preponderate that it is almost impossible to get negative electricity from the idle pole, unless it actually touches the negative pole.

PROPERTIES OF RADIANT MATTER.

One of the most characteristic attributes of radiant matter—whence its name—is that it moves in approximately straight lines, and in a direction almost normal to the surface of the electrode. If we keep the induction current passing continuously through a vacuum tube in the same direction, we can imagine two ways in which the action proceeds; either the supply of gaseous molecules at the surface of the negative pole must run short, and the phenomena come to an end, or the molecules must find some means of getting back. I will show you an experiment which reveals the molecules in the very act of returning. Here is a tube (Fig. 14) exhausted to a pressure of 0.001 mm. or 1.3 M. In the middle of the tube is a thin glass diaphragm, C, pierced with two holes, D and E. At one part of the tube a concave pole, A', is focussed on the upper hole, D, in the diaphragm. Behind the upper hole and in front of the lower one are movable vanes, F and G, capable of rotation by the slightest current of gas through the holes.

On passing the current with the concave pole negative, the small vanes rotate in such a manner as to prove that at this high exhaustion a stream of molecules issues from the lower hole in the diaphragm, whilst at the same time a stream of freshly charged molecules is forced by the negative pole through the upper hole. The experiment speaks for itself, showing as forcibly as an experiment can show that so far the theory is right.

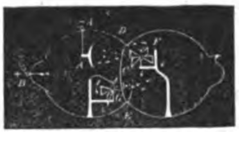

FIG. 14.—P = 0.001 mm. = 1.3 M.

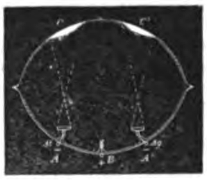

FIG. 15.—P = 0.00068 mm. = 0.9 M.

RADIANT MATTER AND "RADIANT ELECTRODE MATTER."

Some metals it is well known, such as silver, gold or platinum, when used for the negative electrode in a vacuum tube, volatilize more or less rapidly, coating any object in their neighborhood with a very even film. On this depends the well-known method of electrically preparing small mirrors, etc. Aluminum, however, seems exempt from this volatility. Hence, and for other reasons, it is generally used for electrodes.

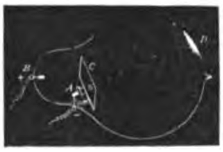

FIG. 16.—P = 0.00088 mm. = 0.9 M.

If, then, the phenomena in a high vacuum are due to the "electrode matter," the more volatile the metal used the greater shall be the effect.

Here is a tube (Fig. 15, P = 0.00068 mm., or 0.9 M.) with two negative electrodes, A, A', so placed as to project two luminous spots on the phosphorescent glass of the tube. One electrode, A', is of pure silver, a volatile metal, the other, A, is of aluminum, practically non-volatile. A quantity of "electrode matter" will be shot off from the silver pole and practically none from the aluminum pole; but you see that in each case the phosphorescence, C, C', is identical. Had the radiant electrode matter been the active agent the more intense phosphorescence would proceed from the more volatile pole.

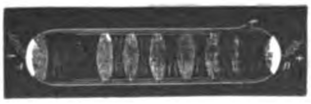

FIG. 17.—P = 2.0 mm.

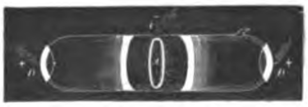

FIG. 18.—P = 0.076 mm. = 100.0 M.

A drawing of another experimental piece of apparatus is shown in Fig. 16. A pear-shaped bulb of German glass has near the small end an inner concave negative pole, A, of pure silver so mounted that its inverted image is thrown upon the opposite end of the tube. In front of this pole is a screen of mica, C, having a small hole in the centre so that only a narrow pencil of rays from the silver pole can pass through, forming a bright spot, D, at the far end of the bulb. The exhaustion is about the same as in the previous tube, and the current has been allowed to pass continuously for many hours so as to drive off a certain portion of the silver electrode, and upon examination it is found that the silver has all been deposited in the immediate neighborhood of the pole, whilst the spot, D, at the far end of the tube that has been continuously glowing with phosphorescent light, is practically free from silver.

The identity of action of silver and aluminum in the first case, and the non-projection of silver in this second instance, prove that phosphorescence is independent of the material of the negative electrode. In front of me is a set of tubes that to my mind puts the matter wholly beyond doubt. The tubes contain no inside electrodes with the residual gaseous molecules, and with them I will proceed to give some of the most striking radiant matter experiments without any inner metallic poles at all.

In all these tubes the electrodes, which are of silver, are on the outside, the current acting through the body of the glass. The first tube contains gas only slightly rarefied and at the stratification stage. It is simply a closed glass cylinder, with a coat of silver deposited outside at each end, and exhausted to a pressure of 2 mm. The outline of the tube is shown in Fig. 17. I pass a current and, as you see, the stratifications, though faint, are perfectly formed.

The next tube, seen in outline in Fig. 18, shows the dark space. Like the first, it is a closed cylinder of glass, with a central indentation, forming a kind of hanging pocket, and almost dividing the tube into two compartments. This pocket, silvered on the air side, forms a hollow glass diaphragm that can be connected electrically from the outside, forming the negative pole, A; the two ends of the tube, also outwardly silvered, form the positive poles, B, B. I pass the current and you all see the dark space distinctly visible. The pressure here is 0.076 mm., or 100 M.

European Correspondence.

LONDON.

Durham Cathedral.—Lighting of the City of London.—New Continental Companies.

It is intended to light the fine old Cathedral Church of Durham by electricity; power will be obtained from the neighboring river Wear.

I mentioned in a previous communication that the Commissioners of Sewers for the City of London had given out contracts for the lighting of the streets to the Brush Company and Messrs. Laing, Wharton & Down, the representatives of the Thomson-Houston system. Of course the city area only extends from Oldgate to Temple Bar, but it is a district which will repay the enterprise. The terms of the undertaking have been made public and are full of interest to electricians.

The provisional orders confirming the contracts differ in many points from other orders. The terms of purchase are considerably modified from the act of 1888, and the sliding scale of the gas acts is adopted, by which consumers are benefited by a reduction in price in proportion to dividends over and above 10 per cent. For instance, the maximum charge per Board of Trade unit is 8d. Suppose the company elect in the beginning to charge at this rate, and suppose they thus earn 11 per cent; for the additional 1 per cent. they are compelled to reduce the charge of 8d. a unit by a half penny and so on.

The Brush Company has already secured a most eligible site of 40,000 feet on the Surrey side, and Laing, Wharton & Down have, I hear, also secured a river side site. As cheapness of fuel is a great consideration, the companies are most fortunately situated.

Eventually the concessions will be transferred to a limited liability company, or it may be two, which will be floated at a favorable turn of the money market. Work, however, is to be commenced immediately, and the two contractors will soon be in the position, as their custom, is of vending a going concern, retaining a proportion of the shares and the engineering control. Of these financial details nothing is yet known, nor in fact is anything settled. They are in the same hands, both in the interests of the Brush Company and of Laing, Wharton & Down, and are understood to rely on powerful and influential support.

The concessions do not interfere with the private lighting, of which there is a good deal in the city, but it is reasonable to expect that consumers will abandon private plants and use current from a central station.

The local authorities have the right to acquire the undertaking, so far as it relates to public lighting, at the end of 21 years upon the terms fixed by the Electric Lighting Act, and they have the right to acquire the undertaking, so far as it relates to private lighting, at the end of that period on paying its value as a going concern. They have the right to buy up at the end of 42 years, or at the end of any subsequent 10 years, upon the terms of the Act, but until the undertaking is so purchased, the concession as to private lighting is not determinable except in the event of certain defaults by the contractors. The contract as to public lighting is determinable by either party at the end of seven, fourteen or twenty-one years. The commissioners have agreed not to consent to any other company obtaining a provisional order during the first twenty-one years. The work of laying the mains has to be commenced before February 19, and completed about two years hence. They have to be laid underground, overhead wires being absolutely prohibited. The preliminary work of equipping the central generating stations is already in progress, and it is expected that the first thoroughfare to be illuminated—Queen Victoria street—will be speedily out of hand. Here, however, there already exists the great convenience of a subway.

The present public lighting bill of the city is rather less than £10,000 a year. The future cost will be rather more than £20,000. Roughly speaking gas lamps of which the probable candle-power is 40,000 are to be replaced by electric lamps of 800,000 candle-power. There are now in each of the three divisions about 1,000 gas lamps. They will be replaced by a gross total of about 400 arc lamps and 1,000 glow lamps. For main thoroughfares arc lamps costing for maintenance £26 each a year will be used, and in smaller streets, lanes and courts glow lamps costing each for maintenance £5 or £10 a year. The arc lamps have each a nominal candle-power of 2,000 candles and they will be placed at intervals of about 250 feet. For private lighting both companies will use the alternating current system, but the pressure will not exceed that of which electrical engineers have had successful experience.

The Anglo-Austrian Bank of Vienna and the firm of Siemens and Halske, of Berlin, have just formed three new electrical companies with headquarters in the former city. The first is the Austrian General Electricity Company, constituted, with a capital of £312,000, for the purpose of constructing and working central electric light stations. The second is the Electric Tramway Company, with a capital of £312,000 for the building and working of electric tramways; and the company have already acquired the Buda-Pesth electric tramway. The third is the International Compressed Air and Electricity Company, with the same amount of capital, and formed to work a concession obtained from the Vienna municipality for lighting the city by electricity.

H. S.

London, Jan. 7, 1891.

LONDON.

City Electric Railway.—Mutual Telephone Co.—Swedish Telephones.—Brighton Company and its Customers.—Meetings of Companies.

The City and South London Railway authorities are going to apply for power authorizing an extension of the existing system to Islington in the North, a distance of two miles. There cannot be a better mark of its general success than the fact that the average number of passengers who use the underground electric line in one day is 25,000. The chief problem to be dealt with by the traffic manager is the enormous crowds of people who wish to travel, and soon the intention to run trains every three minutes instead of five must take effect.

It is announced that the Mutual Telephone Company, Limited, will open for traffic early next month the first section of their Manchester Telephone Exchange, and that they hope to commence work in Liverpool very soon afterwards. Orders for between 1,600 and 1,700 wires have been already obtained in Manchester, and as a considerable number of orders have also been booked in Liverpool the new undertaking may be said to make a hopeful beginning. The rentals will, it is understood, show a considerable reduction upon those at present charged, but the object in view is not so much to reduce rentals as to provide a really good telephonic service, which is certainly badly wanted. This company has secured as manager Mr. A. R. Bennett, late of the National Telephone Company.

The State Telegraph Dept. of the Swedish Govt. has purchased another private telephone concern; this time it is the large Haglind telephone installation which embraces forty central stations in the provinces of Ostergötland, Smaland and Nerika, and has about five hundred subscribers.

The Senate house in Madrid is being fitted with the fixtures for electric lighting.

A novel, and at the same time drastic method has been adopted by the Brighton Electric Light Company in dealing with the opposition which they have encountered from the local authority. Without the permission of this body the company cannot obtain a provisional order, although they have for some time supplied current. They informed their clients that unless they signed an agreement to take current for three years the supply would be cut off. About two-thirds of the total number of customers have agreed to this.

At a meeting of the shareholders of Woodhouse & Rawson, United Limited, held on Friday, resolutions were passed increasing the capital and authorizing the directors to arrange the repayment to the preceding company's liquidations of the amount deposited by them as a dividend guarantee fund.

On the same day was held in London, the first meeting of the French Elmore Copper Company, when M. Secretan was present. It was a mere exchange of compliments between the Board and the shareholders.

Home Correspondence.

BOSTON.

A Board of Gas and Electric Control.—Fire-Alarm Telegraphs.—Elevated Roads.—The Huntington Search Light.

In the Senate this week an order was adopted by Mr. Champlin, of Suffolk, as to abolishing the board of gas and electric light commissioners, and appointing a board of gas and electric light control, to consist of one gas engineer, one electric light engineer, and one lawyer.

At a meeting of the Board of Aldermen the committee on fire department reported an order which was passed for the repeal of so much of an ordinance as gives the inspectors of wires the control of the fire-alarm telegraph system. The fire commissioners claim that the taking of the system from their control was contrary to their views and was detrimental to the best interest of the fire department. The two departments are so closely allied that they cannot be separated, and the efficiency of the fire department is dependent upon the reliability of the fire-alarm telegraph department. Any failure of the latter department would tend to cripple the former and the fire commissioners would be held responsible.

There was a hearing this week before the street railway committee on the petition of the Old South Society and others that the West End Street Railway Company shall not be permitted to build elevated structures, until a commission appointed to examine and determine the best system of elevated railways for the city of Boston shall report upon the expediency of their plan. General opinion appears to be in favor of such a commission, and that there should be an exhaustive inquiry into the modes of rapid transit before allowing an elevated structure to be built. Mr. H. M. Whitney, president of the West End Company, did not oppose the appointment of a committee but accepted it as a necessity, though he believed that its conclusion would be the same already arrived at by the officers of the company.

Some experiments were made this week from the roof of the Edison Illuminating Company, of Boston, on a new 8,500 candle power Huntington search light, which is attracting considerable attention amongst railroad men and those interested in steam navigation.

Boston, Feb. 7, 1891.

Letters to the Editor.

CHEAP LIGHTING IN BUFFALO.

Enclosed please find an advertisement of the Citizens' Gas Co., lowering gas to 75 cents per 1,000 feet. Large consumers have used gas at $1 per 1,000 for several years. I do not think that any municipality in the lighting business furnishes light for less rates. A.

Notice to Gas Consumers.

The Citizens' Gas Co. announces that in those streets in which the mains of said company and of the Municipal Gas Light Co. are both laid, the Citizens' Gas Co. has reduced the price of gas to 75 cents per 1,000 from Feb. 1, 1891.

M. F. Reynolds, President.

Buffalo, Jan. 24, 1891.

ELECTRIC LIGHTING AT SAN DIEGO, CAL.

While enumerating some of the principal institutions of San Diego, Cal., *The San Diego Union* has this to say about the electric light system of the city: "The incandescent system of electric lighting was introduced about two years ago by the Electric Rapid Transit Street Car Company, George D. Copeland, president, and has become an assured success under his management, reducing the rates of commercial and domestic lighting beyond any which ever before prevailed in this city. In fact, the rates for gas and electric lights are now lower in San Diego than those prevailing in other towns on the Pacific coast, where steam power is used, and should the project to use the water-power at the end of the flume materialize, still further reduction in rates may be expected.

"The present Copeland plant consists of two Westinghouse alternating current incandescent dynamos of a capacity of 750 16 candle power lamps each, including exciters, switch-boards and electrical instruments. The dynamos are run by steam power, and so complete are all the operations of the system that there has been no interruption in the regular business of light distribution during the past year."

Society and Club Notes.

SPECIAL TRAIN FOR THE N. E. L. A. MEETING AT PROVIDENCE, R. I.

The Committee on Transportation announce that to accommodate delegates going from and through New York to the ensuing meeting of this Association, at Providence, R. I., they have arranged for a train of parlor buffet cars to leave the Grand Central depot on Monday, February 16, at 1 P. M., arriving in Providence at 6:15 P. M.

Applications for seats must be made to Gen. C. H. Barney, previous to 6 P. M. on Friday, 13th inst., accompanied by a remittance of $1.00 for each seat desired. This is imperative, as the necessary cars will be ordered in on Saturday. Seats will be allotted in the order in which applications are received.

Delegates from points west and south of New York, desiring to take this train, should purchase their through tickets, via "Shore Line Route" from New York.

For the convenience of New York delegates desiring tickets on the certificate plan, and to avoid a rush at the station, a representative of the railroad company will be at the Electric Club, 17 East 22nd street, New York City, on Saturday, 14th inst., at 8 P. M. to deliver tickets and issue certificates.

Single (train) fare from New York to Providence.....	$4.30
Return fare if certificate is obtained...........	1.34
Making the round trip.	$5.64

Extra charge for seats in parlor car, $1.00.

Secretary Foote has issued a very neat and tasteful little pamphlet of 64 pages, giving details as to the Convention, the place of meeting, the invitations from local concerns, etc.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of Feb. 7, 1891, from New York, Boston and Washington; Pittsburgh, Feb. 6.

A DINNER TO PROF. THOMSON.

The departmental foremen, electricians and assistants of the Thomson-Houston company gave a dinner recently to Prof. Thomson at the Parker house, Boston. Professor Thomson gave an interesting account of his early struggles in inventing and perfecting electrical apparatus, and Mr. E. W. Rice, Jr., superintendent of the works, made interesting remarks.

Reports of Companies.

BUFFALO STREET RAILWAY CONSOLIDATION, &C.

The stockholders of the Buffalo Railway Company have effected a complete consolidation of all street railroad interests in that city. Certificates of the surrender of the capital stock of the Buffalo East Side Street Railway Company and the Buffalo Street Railroad Company to the Buffalo Railway Company have been filed in the Secretary of State's office. The Buffalo Railway Supply Company has also filed a certificate of an increase of its capital from $100,000 to $200,000.

THE SEATTLE ELECTRIC RAILWAY LINES SOLD.

An arrangement has been made by which a large portion of the stock of the Seattle Electric Railway and Power Company is transferred to Eastern capitalists. Articles of incorporation have been filed by a new corporation to which the property of the old company was transferred, and which has a capital stock of $1,500,000, divided into 1,500 shares of $1,000 each. This new company takes the name of the Seattle Consolidated Street Railway Company, and the incorporators are F. T. Blunck, of Davenport, Iowa; D. T. Denny, George Kinnear, G. K. Carter, J. E. Porter, Rebecca M. Kinnear, J. F. Hale, V. Hugo Smith, L. H. Griffith, E. C. Kilbourne, J. Furth, A. Dunne, George E. Miller, L. D. Ross, F. M. Griffith.

At a meeting held recently the company was temporarily organized by the election of the following trustees, who will manage its affairs until the second Monday in April: D. T. Denny, J. F. Hale, E. C. Kilbourne, L. H. Griffith, George Kinnear, V. Hugo Smith and J. E. Porter. The majority of the stock still remains in the hands of the Seattle stockholders, so that they will retain control of the property.

THE MERRIMAC VALLEY STREET RAILWAY SOLD.

The change in ownership in the Merrimac Valley Street Railway, at Lawrence, has come to pass, and the road goes into the hands of New York capitalists. Of the 800 shares of stock 760 have been sold at $250 per share. As the old company bought the stock last summer at $150 per share, it makes a handsome profit.

The new owners are William A. Perrin and J. N. Beckley, both of Rochester, N. Y. Albert D. Bosson, of Chelsea and Nathan E. Morton of Lawrence retire from the board of directors, and the New Yorkers take their places. President Ferguson, of Salem, will retain his position, while Albert E. Butler, of Boston, will remain as treasurer. E. P. Shaw, of Newburyport, remains on the board of directors.

The Railroad Commissioners will be asked shortly to authorize the increasing of the capital stock of the road from $80,000 to $300,000. Then electricity will be put in and a line will be built to Andover. All the improvements contemplated by the old company will be carried out by the new owners.

ANNUAL MEETING OF THE CROCKER-WHEELER ELECTRIC MOTOR CO.

At the annual meeting of this company held at their office 430 West 14th street, on Jan. 7, 1891, the following officers and directors were elected for the ensuing year: S. S. Wheeler, president; F. B. Crocker, vice-president; H. H. Crocker, treasurer; and R. N. Peterson, A. F. Higgins, Wm. B. Baldwin, A. K. Sloan, David Crocker, directors. The annual sworn statement showed a full paid capital of one hundred thousand dollars, while the total indebtedness was less than nine thousand dollars, and consisted only of the ordinary open monthly accounts. The statement showed that the business of the company had about doubled in each quarter year.

EAST END ELECTRIC LIGHT CO., PITTSBURGH.

The annual report of the East End Electric Light Company shows gross earnings for the twelve months ending December 31st, 1890, $88,344, and operating expenses of every kind, $46,710, leaving net earnings of $40,733. After the payment of $11,133 interest on bonds and interest and discounts, there remained a surplus of $29,600 or about 5½ per cent. on the capital. The assets foot up $803,887, as follows: Cash on hand, $1,945; accounts receivable, all goods, $41,528; house wiring material on hand, $8,229; horses and vehicles, $1,335; office furniture, $1,761; artesian well and appurtenances, $7,094; interest on bonds accrued but not due, and insurance paid but not charged to expense as yet, $1,092; real estate, $14.423; buildings, $31,126; construction and equipments, $695,319. The liabilities are as follows: Capital stock, full paid, $500,000; first mortgage 6 per cent. coupon bonds due April 1st, 1909, interest payable April and October, $150,000; accounts and bills payable, $108,711; total, $758,711; balance to credit of profit and loss, being net earnings to December 31st, 1890, $45,175.

The floating debt of the company is provided for by an authorized issue of $100,000 second mortgage 6 per cent. coupon bonds, due Jan. 1st, 1911; a portion of which are now being used as collateral for indebtedness. The company has but one accommodation loan of $3.500, the balance of the debt being for vouchers and bills payable for material. As illustrating the growth of the business, it is stated that last month the number of 16 candle-power lamps on the circuit amounted to 20,134 and for the corresponding month the preceding year, 11,508, an increase of 75 per cent. Comparing the net earnings for the same period there was an increase of 127 per cent. For the three months ending December 31st, 1890, the net earnings were $11,588, equal to $46,308 per year, or 9$\frac{3}{10}$ per cent. upon the capital.

POSTAL TELEGRAPH CABLE CO.

At the annual meeting of the Postal Telegraph Cable Company, about 80 per cent. of the stock was voted and these directors were chosen: John W. Mackay, George S. Coe, W. C. Van Horne, John W. Mackay, Jr, Albert B. Chandler, Charles R. Hosmer, James W. Ellsworth, William H. Baker, Edward C. Platt, John O. Stevens, and George G. Ward. All these gentlemen were reelected except the younger Mr. Mackay. The executive committee now consists of Messrs. Coe, Platt, Ward, and Chandler.

Mr. Hector De Castro has resigned his office in this company and also in the Commercial Cable Company. He has been appointed secretary of the International Union of American Republics, which is looking after the Interoceanic Railway project.

ADAMS ELECTRIC CO.

The trustees of the Adams Electric Company, of St. Louis, Mo., have decided to pool the stock for ten years, and have elected the following gentlemen trustees of the pool: Prof. Francis E. Nipher, Hugh Rogers, and Dr. I. G. W. Steedman. This is the original company, with a capital of $25,000. The organization of a new company will soon be effected at Springfield, Ill., with a capitalization of $5,000,000, divided in 200,000 shares. A great portion of this capital stock is represented by the alleged value of Dr. Wellington Adams' patent covering the transmission of electric power, whether from overhead wires, storage battery or conduit, to the electric motor of street railway cars or to any electric motor.

ORGANIZATION OF THE AMERICAN PROJECTILE COMPANY.

The directors of the Thomson Electric Welding Company have decided to organize the American Projectile Company, with a capital of $500,000, for the manufacture of projectiles for the army and navy departments of the United States Government. The articles of incorporation will be prepared at once. The plans of the new factory at Lynn are in readiness, and within sixty days it is expected that the building will be erected and stocked with necessary machinery. The present contracts are to be filled within the ensuing six months. The necessary experimenting has already been done and the factory will start at once upon the regular manufacture of these projectiles. The rights will be given to the stockholders of the Thomson Electric Welding Company to subscribe at par to the stock of the new Projectile Company.

STANDARD ELECTRIC TIME CO.

At the annual stockholders' meeting of the Standard Electric Time Company, the following directors were elected: C. D. Warner, A. W. Paige, and Thomas Wallace, of Ansonia; Frank E. Morgan and Maj. T. Atwater Barnes, of New Haven; H. L. Wade and M. L. Sperry, of Waterbury. C. D. Warner was reelected president, and Geo. W. Huntington, secretary and treasurer.

This company has now 85 isolated, and 16 city plants in operation. Its headquarters will be changed from Waterbury to New Haven, and the business concentrated at that point.

OFFICERS OF THE STANDARD UNDERGROUND CABLE CO.

The board of directors of the Standard Underground Cable Company elected at the annual meeting of the company on January 27th, met Feb. 2, 1891, in the company's office, Westinghouse building, and organized by electing Joseph W. Marsh as vice-president and general manager; Frank A. Rinehart as secretary and treasurer and Oscar R. Ebel as auditor. An executive committee was also created, consisting of John H. Dalzell, Mark W. Watson and Robert Pitcairn, the president or vice-president being ex-offico members.

The promotion of Mr. Marsh is especially gratifying to his many friends, who have watched his career, and who know how thoroughly his long and able management of the business entitles him to the advancement now so gracefully accorded him.

ELECTIONS.

Salem, Mass.—At the annual meeting of the Salem Electric Light Company the old board of directors was re-elected.

St. Louis, Mo.—At a recent meeting of the St. Louis Electric Supply Company, the following directors were elected: H. H. Reese, H. C. Scott, E. Ruebel, and W. L. Scott.

Reading, Pa.—The stockholders of the Reading Electric Light and Power Company have elected the following officers for the ensuing year:—President, James A. O'Reilly, Esq.; secretary and treasurer, J. K. Kighter; directors, James Nolan, Levi Quier, Jesse Orr, Jerome L. Boyer, O. W. Stager, James A. O'Reilly, Esq., F. S. Hastings; auditing committee, George Eltz, Franklin A. Tyson, and W. W. Light. During the year two new boilers and two dynamos have been added.

Denver, Col.—At the annual meeting of the stockholders of the Denver and Berkeley Park Rapid Transit Company, the following officers were elected:—President, Frank Evans; secretary, W. G. Evans; and in addition to the foregoing C. F. Musgrove, C. K. Durbin and J. C. Curtis as a board of directors for the ensuing year.

Northampton, Mass.—At the annual meeting of the electric lighting company, the following officers were elected:—President, Alexander McCallum; treasurer, C. H. Pierce; directors, S. B. Fuller, H. A. Kimball, A. McCallum, E. C. Davis, C. H. Pierce. A 5 per cent. dividend was declared.

Woburn, Mass.—Mr. G. S. Russell has been elected assistant treasurer of the Johnston Electric Train Signal Company.

San Francisco, Cal.—At the annual meeting of the stockholders of the Sunset Telephone and Telegraph Company, the following directors were elected for the ensuing year:—John I. Sabin, president; Monroe Greenwood, vice-president; John E. Hudson, Oliver Eldridge, J. C. Cebrain, E. S. Pillsbury, Fred W. Eaton; also William G. Oliver, secretary and treasurer, and Percy T. Morgan, auditor. And at the same place and day the annual meeting of the stockholders of the Pacific Telephone and Telegraph Company, was held and the following directors were elected for the ensuing year:—John E. Hudson, president; Oliver Eldridge, first vice-president and general manager; Lloyd Tevis, W. F. Goad, Fred W. Eaton and E. C. Pillsbury; also William G. Oliver, secretary and treasurer, and Percy T. Morgan, auditor.

Toledo, N. Y.—The Toledo Electric Company has elected the following officers and directors:—President, E. W. Wilson; vice-president, L. S. Baumgardner; secretary and treasurer, F. B. Dodge; manager, N. C. Stevens. Directors, E. W. Wilson, L. S. Baumgardner, George G. Hadley, J. S. Rodgers, F. B. Dodge, James H. Doyle, A. W. Scott, N. C. Stevens, W. P. Heston.

New York, N. Y.—The Edison Electric Illuminating Co. have elected by unanimous vote, the following directors for the ensuing year: J. E. Brown, E. Crowell, C. E. Crowell, E. A. Doty, F. S. Hastings, C. N. Hoagland, Samuel Insull, D. R. James, Martin Joost, W. H. Murtha, E. Packard, G. F. Peabody and C. M. Pratt.

Kansas City, Mo.—At a recent meeting of the Missouri and Kansas Telephone Company, directors were elected for the ensuing year as follows: S. A. Walker of St. Joseph, George Albree of Chicago, C. E. Yost of Omaha, J. S. Chick and W. B. Clarke of Kansas City, T. B. Sweet and J. R. Mulvane of Topeka, J. E. Hudson of Boston and E. E. Cook of Davenport, Iowa. The following officers were elected: J. R. Mulvane, president; W. W. Smith, secretary; N. R. Ferguson, treasurer; C. W. McDaniel, superintendent; H. W. Crabb, assistant superintendent. J. R. Mulvane, George Albree and J. S. Chick were appointed the executive committee. A dividend of 1 per cent. was declared payable Feb. 10.

Wissahickon, Pa.—The Wissahickon Electric Light Company, at its annual meeting, has elected the following board of directors: President, William Johnston; vice-president, Peter P. Leibert; secretary and treasurer, John Flanagan; James Christie, Leander M. Jones, Andrew Flanagan, and George C. Thompson.

Rochester, N. Y.—At the annual meeting of the Rochester Railway Company, the following directors were elected for the ensuing year: H. Sellers McKee, Pittsburgh; M. A. Verner, Buffalo; E. E. Denniston, Richard M. Clay, Horace Magee, T. De Witt Cuyler, Philadelphia; Benjamin Graham, New York; A. G. Yates, Frederick Cook, W. S. Kimball, A. Luetchford, M. H. Briggs, J. N. Beckley, Rochester. The new board of officers is as follows: President John N. Beckley; vice-president, Benjamin Graham, of the banking firm of John Paton & Co., of New York; secretary and treasurer, Arthur Luetchford; general manager, C. K. Minary.

Shippensburg, Pa.—The Shippensburg Electric Light Company has elected the following directors and officers: Directors, G. W. Thrush, J. C. Rummel, David Gettle, Frank B. Fleming, S. A. Angle, W. W. Stough, James C. Fleming. Officers: G. W. Thrush, president; Frank B. Fleming, secretary; Clarence J. Reddig, treasurer.

Salem, Mass.—The Salem Electric Light Company has elected the following directors: Charles H. Price (president), James F. Almy, I. P. Harris, George M. Harris, S. Fred Smith, Z. A. Gallup, and B. W. Currier, of Lynn.

Fremont, O.—The Fremont Electric Light & Power Co. has elected Frank Heim, president; D. A. Rauck, vice-president; W. H. Ford, secretary and treasurer; W. M. Adams, superintendent.

Detroit Motor Company.—The annual meeting of the stockholders of the Detroit Motor Company was held recently, when the following directors were elected: W. C. Maybury, J. Huff Jones, E. T. Hance, Chas. W. Casgrain, W. H. Ellis, T. B. Rayl and F. A. Blades. The reports of the officers showed a marvelous growth in the business of the company in the last year. The plant just completed is as perfect as that of any electric company in this country.

New Britain, Conn.—The New Britain Electric Light Company at its annual meeting re-elected the old board of directors and chose the following officers: John M. Spring, president; L. C. Whitney, secretary; R. J. Vance, treasurer; and Samuel Bassett, auditor.

Albany, N. Y.—The Troy and Albia Railroad Company has elected the following officers for the ensuing year: President, Charles Cleminshaw; vice-president, A. N. Brady; secretary and treasurer, J. J. Hagen.

Philadelphia, Pa.—The Edison Electric Light Company's stockholders have elected as directors, Samuel B. Huey, D. S. Lindsay, John Lucas, Arthur Colburn, Joseph P. Ord, Amos R. Little, Charles M. Swain, William T. Tiers, Frederick Prime, George B. Woodman and R. F. Work. The board was later organized by the election of Frederick Prime, president; Samuel B. Huey, vice-president, and A. V. Sloan, secretary and treasurer.

STOCKS AND BONDS.

Increase of the Troy and Albia Railroad Company's Capital.—The application of the Troy and Albia Horse Railroad Company for permission to increase its capital stock from $50,000 to $400,000 has been approved by the State Railroad Commission. It is stated that the cost of construction and equipment of the road to date is $83,793; that the amount of capital stock outstanding is $44,700; and the amount of bonds outstanding, $34,000. The cost of construction aud equipment to date is apparently $5,995 in excess of the outstanding obligations. The cost of construction and equipment for the electric operation as proposed is put at $241,000; that for the proposed new road through the fifth ward and Hoosick street, 2½ miles, $175,000, making a total of $416,400.

Boston, Mass.—The report that the Thomson-Houston Co. is acquiring the Westinghouse Co. is denied. Westinghouse stock has advanced to 16¼.

Canton, O.—The Canton Electric Light and Power Company, of Canton, O., has increased its capital stock from $50,000 to $100,000.

Appleton, Wis.—The city of Appleton, Wis., will issue bonds to the amount of $43,000 for the purpose of installing a street lighting plant.

New Iberia, La.—The stockholders of the Electric Light Company of this place met last week for the purpose of raising the necessary funds to cancel an outstanding indebtedness. The reports showed that 178 shares of the stock had been taken, and 22 shares not taken; that there was a debt of $1,850 to be paid, and that with the amount which would be realized from the sale of these shares, together with the cash on hand, the debt could be paid. In accordance with this report the 22 shares were offered at their face value on three and six months and in less than fifteen minutes were taken up. There is no stock for sale now at less than a premium.

DIVIDENDS.

Lowell, Mass.—At a recent meeting of the directors of the New England Telephone and Telegraph Company, a dividend of $1.25 per share was declared, payable on Saturday, Feb. 14, 1891, to stockholders of record at the close of business on Saturday, Jan. 31, 1891. The transfer book will be closed from Feb. 1 to Feb. 14, 1891, both days included.

Cambridge, Mass.—The Cambridge Electric Light Company has declared a semi-annual dividend of 3 per cent. payable Feb. 2.

Boston, Mass.—The Erie Telephone Company has declared a quarterly dividend of one per cent. payable Feb. 16 to stockholders of record Feb. 7, transfer books closing at 12 M., Feb. 7, and reopening Feb. 16.

Boston, Mass.—It comes from semi-official sources that the Thomson-Houston Electric Company has the money in bank to declare a dividend on the common stock, and that the same will be declared payable about February 1.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED FEB. 3, 1891.

Accumulators :—

Secondary Battery. H. T. Cheswright, 445,542. Filed Apr. 14, 1890.
Electrode consists of a number of lengths of ribbed pipes of lead or alloy held in a suitable frame and having the intervals between their ribs charged with lead oxide.

Electrode for Secondary Batteries, S. H. Barrett, 445,872. Filed Nov. 1, 1890.
Electrode consists of a frame having a series of dividing ribs or partitions which are flush with the face of the plate, and divide the frame into a series of openings, together with a further series of partitions or ribs flush with one face of the plate and below the other face of the plate, and which subdivide the above-mentioned openings into a series of smaller openings.

Alarms and Signals :—

Electric Signaling Device, S. J. Burrell and W. H. Markland, 445.538. Filed June 4, 1890.
Relates to systems of signaling in which any one of a number of stations upon a circuit may call or signal to any other station only; as for instance, the case of a number of telephone stations upon a single circuit; also applicable to railroad service, as for the despatching of trains or the giving of other orders. Embraces devices for avoiding the disturbance or operation of the instruments at stations other than the one it is desired to communicate with.

Non-Interference Signal-Box, M. G. Crane, 445,545. Filed Nov 22, 1889.
Designed to render the signaling mechanism inoperative if at the moment that it is desired to transmit a signal the line be in use. Employs a movable connecting plate which controls the operation of the signaling mechanism, and a non-interference magnet operating to move the connecting plate.

Electrical Station-Indicator, E. S. Ely, 445,773. Filed May 28, 1890.
Electro-magnetic mechanism, controlled by a push button or similar device, to roll a strip containing the names of stations and exhibit each as required.

Successive-Non-Interference Signal-Box, F. W. Cole, 445,795. Filed Nov. 22, 1889.
An independent time-train is employed to move the clog, stop, or hold-fast in one direction; it is moved or held in the opposite direction by a spring or its equivalent, both movements being under the control of a non-interference magnet.

Electric Visual Indicator, F. W. Cole, 445,796. Filed March 7, 1890.
Designed to display many different numbers for fire-alarm and other similar purposes, and consists of details of electro-magnetic apparatus for actuating a series of drums having numbers upon their surfaces.

Repeater, F. W. Cole, 445,797. Filed April 12, 1890.
An automatic repeater adapted to be used in non-interference fire-alarm systems or other similar electric circuits.

Successive Non-Interference Signal-Box, F. W. Cole, 445,798. Filed May 16, 1890.
The retarding or non-interference devices of several boxes on a circuit are arranged to take different periods of time for their operation; so that if several boxes are operated at or about the same time the first one which opens the circuit will obtain the line and the rest will be held till the first signal be completed, when the box having the next shortest time-retarding device will follow with its signal and so on.

Non-Interference Signal-Box, F. W. Cole, 445,799. Filed May 29, 1890.
The power of the non-interference magnet is controlled by a switch, which is in turn controlled by the box-door. This is to prevent the armature responding to the impulses from another box when the home box-door is open.

Successive Non-Interference Signal-Box, F. W. Cole, 445,800. Filed May 31, 1890.
Details of construction and operation.

Successive Non-Interference Signal-Box, F. W, Cole, 445,801. Filed Nov. 14, 1890.
Contains a windable signaling mechanism, a non-interference magnet, means for sending a signal and means for retaining the set signal when the line is in use, and means for releasing the signaling mechanism on a closure of the signaling circuit of duration longer than the longest closure employed in any signal.

Successive Non-Interference Signal-Box, F. W. Cole, 445,802. Filed Oct. 10, 1889.
Contains a stop for the signaling mechanism, a restorer for normally holding the stop-lever in position to lock the signaling mechanism, a non-interference magnet, a retarding device and a clog controlled by the non-interference magnet and acted on by the retarding device for holding the stop-lever in position still to lock the signaling mechanism after it has been released by the restorer.

Electric Fire-Indicator, T. R. Douse, 445,931. Filed Nov. 1, 1890.
A thermostat actuated by heat-expansion of air, alcohol, mercury or other agent hermetically enclosed in a box. Electric contacts are closed by the expansion of the box, the top and bottom of which are corrugated. Thermometric markings are provided by which the apparatus can be set to act at any given temperature.

Conductors, Conduits and Insulators :—

Electric-Conductor Support, C. Foster & W. H. Bevis, 445,594. Filed July 30, 1890.
Especially applicable to overhead conductors for electric railways.

Wire-Covering Machine, J. McCahey, 445,598. Filed April 15, 1890.
An improved winding machine for covering electric or other wires.

Electric Wire Connector, J. W. Hoffman, 445,751. Filed Aug. 22, 1889.
Epecially applicable to joining, between the cars, the conductors employed in lighting railway trains.

Insulator, H. D. Winton, 445,790. Filed July 23, 1890.
A "break" insulator especially designed for looping a circuit of electric lamps, telephones or other translating devices. Applicable to overhead wires. Metallic hooks, cross-heads, or equivalents are molded, cast or otherwise embedded within the block of insulating material in such a manner that they interlink within the material without coming in contact with each other.

Dynamos and Motors :—

Electric Motor, F. J. Patten, 445,623. Filed Oct. 6, 1890.
An alternating-current motor. Consists substantially of two independent machines, the armatures of which are upon a common spindle; the field-magnets are connected to separate sources of alternating-currents; the supply circuits are periodically and alternately short-circuited by groups of commutator segments suitably connected together. The principle of the invention is summed up in claim 8 as follows: The described method of utilizing alternating currents in the transmission of energy which consists in converting currents into two independent like sets of secondary currents and causing these two to successively excite the operative circuits of the machine.

Electric Motor, F. J. Patten, 445,624. Filed Oct. 18, 1890.
Amplification of No. 445,623 above. Claim 10 follows: The method of operating electric motors on alternating-current circuits, which consists in connecting the operative circuits of two independent machines, the rotary parts of which are carried by a common spindle to a source of alternating current through commutators that short-circuit or cut out the exciting-circuits of each machine in turn during the period of time that the circuits of the other are excited by the current from the source of supply.

Electric-Motor Switch, F. A. Weller, 445,741. Filed Feb. 1, 1890.
Relates to means for starting and stopping electric motors on constant-potential circuits and adapted to graduate the rush of current through the motor upon starting and to break circuit promptly for stopping. Establishes the main line current through the field coils in advance of establishing the circuit through the armature coils, and employs resistance coils in connection with the switch for graduating the initial flow of current.

Dynamo-Electric Machine. C. J. Schwarze, 445,906. Filed Oct. 2, 1890.
Relates to the form and construction of the field magnets. The frame, field-magnet, cores and pole-pieces are integral with each other; the sections of the frame used as cores are rectilinear lengthwise and cylindrical in section.

Starting Device for Electric Motors, E. P. Sharp, 445,907. Filed March 18, 1890.
For controlling and graduating the current passing through the motor at starting and for indicating any failure of such control or graduation. Consists in a rotary mechanism combined with a series of resistance-coils and contacts, by which the resistances are cut out of circuit one after another; employs an electric lamp or other signal so connected as to be brought into action by any abnormal increase of current.

Ignition :—

Electric Gas-Lighting Apparatus, H. H. Cutler, 445,727. Filed May 6, 1890.
Relates chiefly to a circuit-closer for gas-lighting apparatus employed in lighting street lamps.

Electric Gas-Lighter H. H. Cutler, 445,728. Filed March 15, 1890.
For lighting street lamps. Comprises appliances for turning on and lighting the gas and for turning off the gas, and adapted for including in one circuit, in series, a large number of lamps. Employs powerful currents such as those used in electric lighting.

Lamps and Appurtenances :—

Electric-Arc Lamp, J. W. Easton, 445,546. Filed Feb. 19, 1890.
Employs a rack and pinion feed. Contains an escapement wheel controlling the pinion, a pivoted frame on which the escapement wheel is mounted, an escapement mounted on the fixed frame of the lamp, and means for adjusting the position of the axis of the escapement, by which the lamps may be arranged to burn at any desired voltage.

Mast-Arm for Electric Lights, G. Fitch, 445 549. Filed July 3, 1890.
Claim 1 follows:
In a mast-arm, the combination of a main arm pivotally connected at the inner end, and a secondary counter-weighted balancing arm pivoted at a point below and connected to the main arm by equalizing links and levers.

Cut-Out for Incandescent Lamps, T. D. Bottome, 445,686 Filed July 25, 1889.
Lamp has a straight filament mounted at right angles in two spring-arms having a portion of their inner adjacent faces near the ends carrying the filament, normally separated so long as the filament remains intact, and adapted to close the circuit upon the rupture of the filament.

Incandescent Electric Lamp, T. D. Bottome, 445,688. Filed Nov. 8, 1890.
Relates to the conductors or leading-in wires of incandescent lamps. Employs an alloy of silver, platinum and nickel or cobalt.

Electric-Arc Lamp, O. C. White, 445,724. Filed Nov. 7, 1889.
The clamping-blocks, formed like sections of a ball or sphere, are enclosed in two opposing rings forming sockets within which they are capable of turning; the tension of a spring is employed to bring the enclosing rings together and compress the clamping blocks.

Electric Switch, J. W. Hoffman, 415,752. Filed Feb. 4, 1890.
A switch especially applicable for electric lighting and particularly designed to prevent sparking, by exceedingly quick action.

Electric Cut-Out, G. A. Scott, 445,822. Filed Aug. 13, 1890.
A fusible cut-out for electric lighting circuits.

Reel for Raising and Lowering Electric Lamps, J. T. Roberts, 445,908. Filed July 26, 1890.
Special contrivance of brake mechanism and devices for attaching or supporting the reel.

Electric Switch, G. R. Lean, 445,957. Filed March 24, 1890.
Especially applicable to lighting and power circuits and adapted for switching a loop into and out of circuit with a main line wire.
Claim 1 follows;
In an electric switch, two main line blocks and a switch between them, two branch line blocks and a switch between each branch line block and the main line blocks, the movable members of the branch line switches operating in advance of the movable members of the main line switch at every movement thereof.

Medical and Surgical :—

Electrical Medical Apparatus, J. C. Chambers, 445,636. Filed April 21, 1890.
A combination of a battery, induction-coils and other suitable apparatus and appliances for administering electricity in a variety of ways, and all mounted in a cabinet suitable for a physician's office.

Metal Working :—

Method of Electric Soldering and Cementing Cans, M. W. Dewey, 445,770. Filed Sept. 27, 1890.
Consists in heating the soldering-tool by passing an electric current through a conductor in close proximity or contiguous to the tool while it is remote from the work, and then moving the tool from the conductor and into contact with the work.

Apparatus for Soldering and Cementing Cans by Electricity, M. W. Dewey, 445,771. Filed Sept. 27, 1890.
Details of apparatus for carrying out the method of patent No. 445,770 above.

Miscellaneous :—

Apparatus for Electric Branding, W. Cannell, 445,648. Filed April 8, 1890.

Employs a high resistance branding-plate, largest in the middle and of gradually diminishing cross section toward the opposite ends and forming a portion of the secondary circuit of an electric transformer.

Apparatus for Testing Metal Pieces, L. De Place, 445,860. Filed Nov. 11, 1890.

Application of the "Schiseophone" to the detection of flaws in metal. Claim 1 follows :

An instrument for testing metal objects, comprising, in combination, a microphone or telephone transmitter in an electric circuit, including a coil or helix, a striker in close proximity to said microphone, a secondary coil or helix, and a telephone receiver in circuit therewith.

Asymmetrical Electrical Resistance, T. D. Bottome, 445,687. Filed Jan. 28, 1890.

A resistance device through which the current will flow freely when passed in one direction but will be resisted or nearly stopped when applied in a reverse direction. Consists, essentially, in an electro-chemical apparatus having conducting plates of chemically inoxidizable metals immersed in a conducting fluid consisting largely or entirely of sulphuric acid or a solution of a sulphate; one of the conducting plates being composed of metallic aluminum.

Railways and Appliances :—

Automatic Circuit-Closing Device for Railroad Signals, I. W. Loy and R. O'Toole, 445,564. Filed April 12, 1890.

Relates to the design, construction and operation of circuit closers placed beside a railroad track to be actuated by passing trains.

Rolling-Stock for Tramways or Railways, C. Zipernowsky, 445,583. Filed Sept. 22, 1890.

Relates to the mounting of motors upon railway trucks and to the arrangement of driving gear. The motor has its field-magnet sleeved on extensions of the axle-boxes of the driving-axle at one end and is supported by a movable connection to the body of the vehicle at the other end. The motor is mounted with its armature shaft longitudinal with the car and is connected to the driving axle by a worm-gear and a toothed gear upon the driving axle.

Contact Device for Electric Railways, E. M. Bentley, 445,634. Filed Sept. 20, 1888.

For conduit electric railways. Specially adapted for convenient and ready removal from the conduit and replacement, as required at "cross-overs."

Electric Semaphore, F. Stitzel and C. Weinedel, 445,653. Filed Dec. 21, 1889.

A system of apparatus and circuits for the operation of railway signals, adapted to the "block" system.

Regulator for Electrically-Propelled Vehicles, S. H. Short, 445,654. Filed Oct. 17, 1890.

Claim 8 follows :

An electrical regulator comprising a reversing switch and an adjustable rheostat or intensity-regulating means, together with two movable operating devices mechanically connected, one with the reversing switch and the other with the rheostat, and having said devices each insulated from the current to be regulated and each in electrical connection with the ground.

Electric Railway, R. M. Hunter, 445,674. Filed Jan. 14, 1889.

Relates particularly to contact-devices or collectors on the car for use in conduit systems, and especially adapted to a conduit outside of the track.

Coupling for Trolley-Wires of Electric Railways, S. H. Short, 445,841. Filed Oct. 29, 1889.

The connector has grooves for the reception of the wires, and inclined holes extending through the coupling in such a manner that the ends of the wires may be bent over or otherwise secured at the top of the connector.

Trolley-Wire Holder, E. P. Sharp, 445,908. Filed Sept. 25, 1890.

Wraps the trolley-wire with a thin and ductile metal strip secured to the holder by a single joint on the upper side.

Electric Railway, R. M Hunter, 445,952. Filed Sept. 28, 1886.

Claim 1 follows :

In an electric railway, the combination of a line conductor extending along the railway, electrically propelled cars moving on said railway and receiving current from the conductor, an electric generator for supplying current to said line conductor, and two or more feeding conductors connecting one pole of the generator with different distant parts of the line conductors.

Electric Car-Lighting, L. F. Jordan, 445,954. Filed Nov. 16, 1889.

System of circuits and appliances for car lighting, especially applicable to electric railway cars, and embracing details of devices for electrical connections between cars when made up in trains.

Telegraphs :—

Autographic Telegraph, H. Etheridge, 445,715. Filed March 7, 1890.

Relates to improvements in transmitters for autographic telegraphs of the variable resistance type employed by the Writing Telegraph Company.

Automatic Switch for Autographic Telegraphs, H. Etheridge, 445,716 Filed Oct. 29, 1888.

Relates to means for controlling the circuits between subscribers and the central office in an autographic telegraphic exchange system.

Telephones and Apparatus :—

Telephone Box or Cabinet, B. A. Stevens, 445,721. Filed May 26, 1890.

A cabinet for telephone subscribers provided with sound-deadening walls and ceiling and with sound-vents which may be closed while the subscriber is talking, and be left open at other times to permit a call to be heard outside.

Appointments, Etc.

Mr. Edward Lewis has been appointed superintendent of Middletown Electric Light Company, of Middletown, Conn.

Mr. E. G. Pike has been appointed superintendent of the telephone service of Upper Peninsula of Michigan.

Mr. Charles A. Gates has been appointed superintendent of the telephone exchange at Jackson, Mich.

Mr. B. J. Arnold, who has represented the Thomson-Houston Electric Co. as agent and engineer at St. Louis during the past eighteen months, has been appointed consulting engineer for the Western department with headquarters at Chicago.

Mr. H. K. McCay, for three years manager of the Edison Elec. Ill. Co., of Birmingham, Ala., has accepted the position of manager of the Amsterdam Elec. St. Ry. and Edison Elec. Lt. & Power Co., of Amsterdam, N. Y.

Legal Notes.

THE EDISON COMPANY SUED.

Arthur D. Johnson, of Lynn, has brought suit against the Edison General Electric Company for $30,000 damages. On the 11th day of October he was in the employ of the Edison Company, at Salem, Mass., and while at work on the platform of a tower wagon, adjusting a trolley-wire, fell to the ground, a distance of sixteen feet, and sustained serious injuries. The fall was occasioned by the breaking of a bracket used for the purpose of drawing an electric wire taut, and because of the wagon platform not being sufficiently guarded with a railing.

G. F. CORLISS vs. THE MANSFIELD ELECTRIC STREET R.R. CO.

Suit has been filed against the Mansfield Electric Street Railroad Company, of Mansfield, O., by G. F. Corliss, claiming $300 damages for the use of his patent. He is the patentee of a spiral spring, his letters patent bearing the date of April 29th, 1890. The spring is placed in boxes on the cars to keep the wire taut which draws the double trolley. Corliss was in the employ of the company about a year ago, at which time he invented the spring. It has been in constant use ever since. The car company will fight the case.

AN ADVERTISING COMPANY'S SUIT FOR DAMAGES.

A novel suit has been brought by an advertising company against the electric street railway company, of Peoria, Ill. Indicators containing advertisements and "next street" were put in the cars and there was an agreement made that the curtain should be pulled every block, but it would seem from this suit that this has not been done, and advertisers have brought suit for $5,000 damages. The outcome of this suit will be noted with interest by the public for the reason that when it comes to trial the various and multifarious duties of a conductor on a car will be defined.

THE BOSTON SUBURBAN LIGHT AND POWER COMPANY'S PETITION DISMISSED.

An important decision has been rendered by the full bench of the Supreme Court in the case of the Suburban Light & Power Company against the Board of Aldermen of the city of Boston.

These were petitions for an order directing the defendants to specify in writing where in the highways of the city the petitioner might erect poles to enable it to perform an alleged contract made with the city for lighting certain streets. Both petitions are dismissed, and the opinion, which was written by Judge Devens and approved after his death by the other justices, clearly defines the power of boards of aldermen and selectmen to regulate the use of streets in connection with electric lighting companies.

SETTLEMENT OF AN ELECTRIC RAILWAY INJUNCTION.

A settlement has been effected between the Southern Railroad Company and the Union Depot Railroad Company, of St. Louis, Mo., in regard to the occupancy of a track on Ninth street, between Russell and Lafayette avenues. Both companies use the same track in the locality named, but when the Southern began to string electric wires the Union Depot Company applied to the Circuit Court for an injunction, claiming that two electric railroad companies could not use the same track at the same time. A stipulation was filed by which the case has been dismissed. It was agreed that both companies should use the same track and the same wire in the disputed locality by a system of cut-offs and switches which are set out in full.

T. W. PEARSALL vs. WESTERN UNION TELEGRAPH CO.

The Court of Appeals has rendered a decision in the case of T. W. Pearsall against the Western Union Telegraph Company, affirming the judgment of the lower court in favor of the plaintiff. This was an action to recover damages for the alleged negligence of the defendant in failing accurately to transmit a telegraphic message from Great Neck, L. I., to New York. On July 31, 1884, some person on behalf of the plaintiff delivered to a telegraph operator at the station of the Long Island Railroad at Great Neck, without prepayment, a message for transmission to New York, addressed to "T. W. Pearsall & Co.," telling them to buy 1,000 shares of Western Union. This message was written, not upon one of the printed blanks of the company, but on an ordinary sheet of note paper, with no conditions whatever printed thereon.

The message was delivered at the place directed and paid for, but the words "& Co." had been omitted, the address reading simply "T. W. Pearsall." No person in the office of the firm possessed authority to open a message thus addressed, consequently the telegram remained unopened until Mr. Pearsall arrived. In the meantime the price of Western Union had gone up, and when the plaintiff purchased the stock on his return to the city he had to pay a higher rate than if it had been purchased at the time he telegraphed. He sued for the amount represented by the advance in price, recovered judgment, and the Court of Appeals now affirms the judgment.

THE McKEESPORT ELECTRIC LIGHT CO.

A bill in equity has been filed by the Edison General Electric Company, the Edison Light Company, Samuel Insull, Thomas Petty and F. H. Busch, against the McKeesport, Pa., Light Company, Thomas L. White, president and director, and Thomas Reynolds, James E. White, Henry Reiber and James S. Kuhn, acting directors.

The plaintiffs, it is asserted, own 1,065 shares of the 1,843 shares of stock issued by the McKeesport Light Company. At the annual meeting on October 14, 1890, an amendment to the bylaws was passed increasing the number of directors from five to seven. The directors and White, who comprised the minority stockholders, obstructed the business of the meeting, preventing an election, with the intention of remaining in office indefinitely. A call for a special meeting was refused and an application was made to court for a mandamus on the president to call a special meeting. The mandamus was refused, but the opinion of Judge Ewing was strongly in favor of the plaintiffs. On the strength of the opinion White then called a special meeting. The plaintiffs were present, but of the minority stockholders only White and Secretary Reiber, representing 41 shares, were present. This left them without a necessary quorum of two thirds of the stock, as required by the by-laws, and White declared they could not hold an election.

The plaintiffs say that though they have a lawful right to control the affairs of the company, they are not represented on the board of directors and have no share in the management. They therefore ask that a receiver be appointed to take charge of the business, and that the defendants be restrained from exercising the functions of officers or interfering in any way with the business.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"Back up your 'drummers' with live advertising."

BAIN ELECTRIC MANUFACTURING CO.

Mr. Forée Bain, the well-known electrical manufacturer and expert of Chicago and one of the pioneers in many of the branches and recent developments in electrical mining and power transmission work, has recently incorporated his old and long established business under the name of Bain Electric Mfg. Co. This action has been rendered necessary owing to the large demand for his dynamos and motors, which he will now manufacture in large quantities, keeping all sizes in stock and will immediately remove to No. 47 and 49 S. Jefferson street, where he has secured very extensive and commodious quarters which will be immediately equipped with the latest and most improved machinery for heavy work, such as building 500 h. p. motors and dynamos for distribution of light and power. Mr. Bain is president and engineer of the company, and as heretofore will devote a considerable portion of his time to expert consulting electrical work and also to the application of electricity to all industrial and new uses. He will also pay attention to supervising the building and equipment of electric street railways in which line his name has become widely known in connection with the vast enterprise of this kind in Minneapolis and St. Paul, and it is in a large measure due to his intelligent supervision and the perfection in detail which he has had carried out there, that the operation of that large system is so eminently successful.

HOTEL HANDBOOK.

The Traders and Travelers' Accident Co., of New York, have issued in very neat form, for carrying in the pocket, a hotel handbook and guide. It gives the name of the place, the hotels, their rates, and the population. The towns and cities are arranged alphabetically under their respective States, and the States are also arranged alphabetically, so that specific or general reference can be immediately made. The name of the State is also printed in prominent lettering at the top of each page. The book measures 5 x 2¾ inches, and has a flexible cover. At the end is a calendar for 1891. The price is 75 cents. It is well worth the money and should prove of value also to the company as a means of advertising their excellent system of accident insurance.

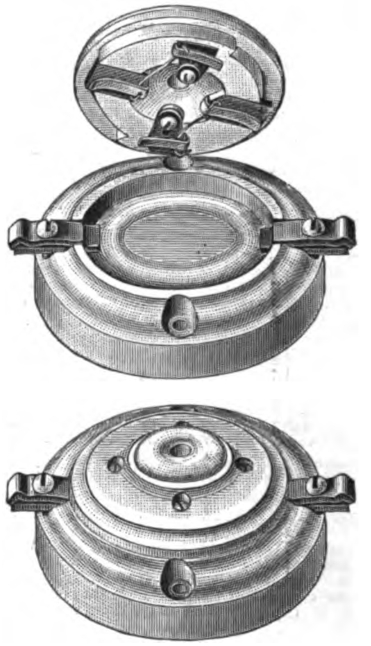
THE EMERSON SPRING CLIP CUT-OUT.

The Emerson Electric Manufacturing Co., of St. Louis, have just brought out a novelty in the shape of a ceiling block known as the "spring clip cut-out." The object has been to produce a cut-out of simple construction, easily fixed to the ceiling, and convenient for renewing the fuse wires.

The accompanying engraving, Fig. 1, shows the cut-out with the cap removed. To the base are attached the main terminals, which consist of two flat pieces of brass, which can be pressed together by means of slot headed screws. The mains are connected by simply stripping the insulation for the space of half an inch, slipping them into position between the plates and turning the screws. The plates project into the central opening and form catches, under which similar catches on the cap piece engage when placed in position. To the cap piece are attached four sprig clips, two of which are attached to, and form part of, the lamp terminals. These lamp terminals are provided with the usual slot-headed screws and washers, under which the flexible ends are attached. The other two spring clips are attached to, and form part of, the catches which engage with the two catches on the base, when placed in position.

The fuse wires are attached by simply slipping the ends under the spring clips of the catch plate, and lamp terminals, respectively, as shown in Fig. 1.

The cap is placed in position by pressing it into the central opening of the base and turning it to the right, until it engages the catch plates of the base. This action engages the springs with the annular ridge in the base and causes the spring clips to be pressed tightly against the fuse wire ends, slightly flattening them and insuring a good connection. This prevents the fusing that is incidental to defective contact. The spring clips which are attached to the catch plates also perform another important function; they slip into slight dents in the annular ridge, thus locking the cap into place and preventing the possibility of its becoming loose by vibrations. The engraving, Fig. 2, shows the cut-out complete with the cover in position.



Figs. 1 and 2.—The Emerson Spring Clip Ceiling Block.

EUREKA TEMPERED COPPER CO.

One of the Eureka tempered copper boxes was placed in the service of the Pennsylvania R. R. Co., between Kane and Renovo under tender of engine No. 2020, March 21, 1887, and taken out October 30, 1888, having made 96,347 miles. Box was in good condition and showed but little wear.

Another was placed in same service between Kane and Erie, Pa., and used over two years, and was taken off in good condition, showing no lateral wear and but little wear upon its face, having made 155,000 miles.

THE CENTRAL ELECTRIC CO.

Since the Central Electric Co. decided to go into the railroad supply business, they have been looking thoroughly into the subject, and announce that they will shortly be upon the market with some railroad specialties entirely their own. These will be announced and illustrated in due time.

AN ELECTRIC EXERCISING MACHINE.

The accompanying illustrations show a novel device manufactured by the American Electric Exercise Machine Co., of New York and Chicago.

Fig. 1 shows the machine in use, and its operation will be clearly understood by reference to Fig. 2, which shows the magneto-electric apparatus geared to the drums on which are wound the exercising cords. When the machine is in use a gentle current is generated by the operation of the magnet so that it may be graduated at will. The electric apparatus may, however, be disconnected, and the machine used as a simple health-lift, or, on the other hand, it may take the place of a medical battery and be used to supply a current alone.

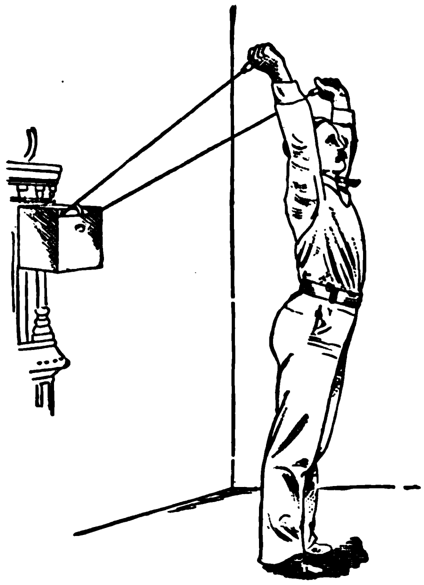


FIG. 1.—AN ELECTRIC EXERCISE MACHINE.

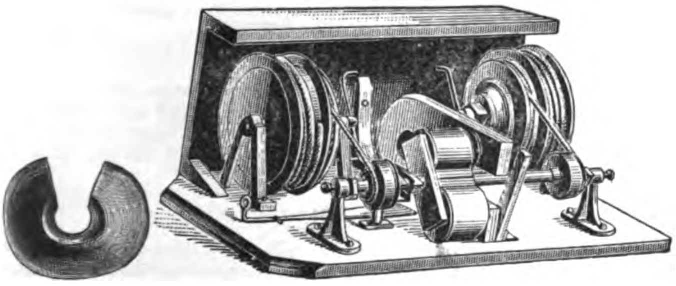


FIGS. AND 3.—AN ELECTRIC EXERCISE MACHINE.

The manufacturers claim that highly beneficial results are obtained by the use of the device, and especially recommend it to those whose occupations cause muscular pains in the hand or arm.

ELECTRICAL SUPPLY CO., CHICAGO.

The Electrical Supply Co., of Chicago, have received the following letter from the Mountain Electric Co., Denver: "In installing isolated plants throughout this state, we carefully investigated the various makes of rubber covered wire. After sending for samples of nearly every standard brand, we finally decided to use Habirshaw wire solely, for the reason that we consider it the best. To indorse this statement we think it only necessary to add that the cost of the wire is higher than any other wire quoted us. We are very glad to inform you that we shall soon send in an order for a large quantity of this wire, as we have recently obtained the contracts on three new buildings. Trusting that this will give you a practical proof of what we think of Habirshaw wire, we are, etc."

F. P. LITTLE & CO.

Mr. W. H. McDonald has severed his connection with the firm of Little, McDonald & Co., and the firm will be continued under the name of F. P. Little & Co., who assume all liabilities and to whom all bills due should be paid. The parties forming the new firm are F. P. Little, S. F. Eagan and P. P. Miller. The business will be carried on as before at 141 East Seneca street, Buffalo, N. Y.

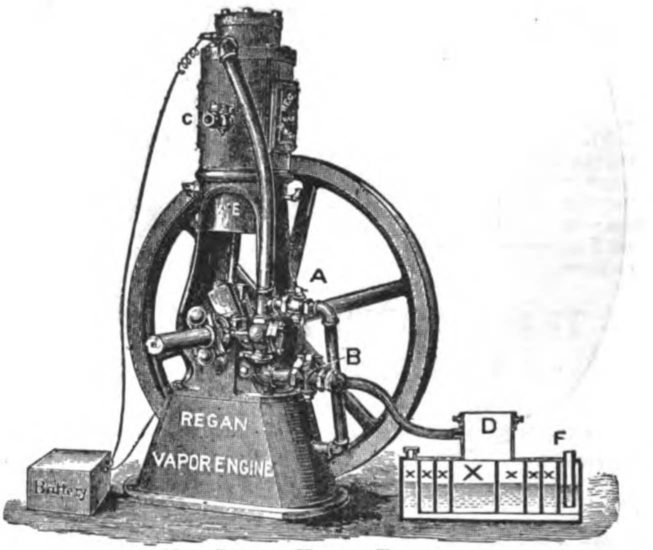
THE REGAN VAPOR ENGINE FOR ELECTRIC LIGHTING.

The increasing tendency to use gas instead of coal for motive power is clearly shown by the large number of gas engines now in use. The Regan Vapor Engine differs essentially from others of its class, inasmuch as it contains no flame igniting device, the charge being fired by a spark from an ordinary wet or dry battery, as described below. It can therefore be left to itself in a house, store or barn with perfect safety.

While gas can be used for fuel, the Regan engine runs as well with gasoline. The accompanying engraving illustrates the upright type of engine, showing the carburetor and small battery complete.

It is operated by means of vapor drawn into the cylinder by the suction of the piston, and ignited by an electric spark, as follows: The carburetor contains a small quantity of gasoline, and is connected with the engine by a pipe, as shown. At each revolution of the fly-wheel a current of cool air is drawn through the carburetor and into the cylinder. In passing through the carburetor, it vaporizes a quantity of the gasoline; this, when mixed with more air drawn through the pipe and air-valve, forms the charge which, upon combustion, develops the power.

On the return stroke the charge is compressed in the head of the cylinder, and just before the piston arrives at its highest point, or "upper dead centre," a shoulder or point projecting from it, which is an electrode, comes in contact with a flexible piece, also an electrode, the two comprising the poles of the small battery; thus completing an electric circuit which is broken just as the piston has passed its "centre" and commences to descend. At the instant the electrodes separate, the spark is emitted, firing the charge. On every other stroke of the piston this is repeated automatically, save when the supply is "cut off" by the governor, which not only controls the engine perfectly, but at the same time "cuts off" the supply of gas, so that when less power is being used, proportionately less gas or vapor is consumed.



THE REGAN VAPOR ENGINE.

The Regan vapor engine is built both upright and horizontal, from ½-h. p. upwards, both for stationary and marine purposes.

This engine is manufactured by Thomas Kane & Co., of Chicago, and is extensively used in California, where it was invented.

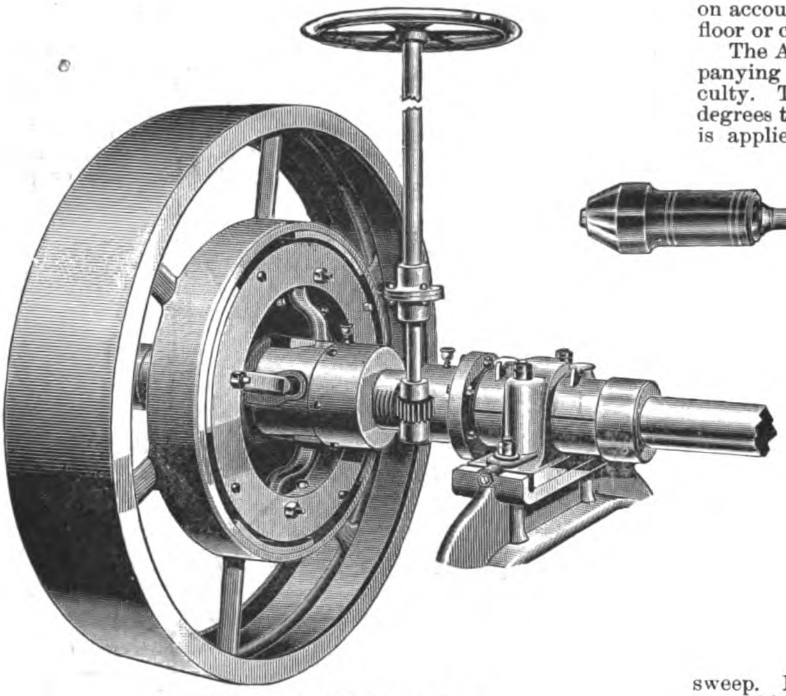
THE EMPLOYERS' LIABILITY ASSURANCE CORPORATION LIMITED.

Endicott & Macomber, the managers and attorneys of the above corporation in this country, have issued, from their Boston headquarters, a very handsome pamphlet setting forth its objects, and describing the insurance that it furnishes employers against injuries to workmen. It issues policies indemnifying against any compensation or damages that employers may be required to pay as the result of legal proceedings, or which, with the concurrence of the corporation, the employers may agree to pay in respect to accident to workmen. Issued in the same way are a variety of other policies, such as the Outside Liability, the "Workmen's Collective," the General Liability, the Elevator and General Accident. These comprehend, in their range, all the accidents that belong to modern life and methods of labor, and the company enjoys a large and increasing business as the result of its liberality and its well devised system. The insurance offered by the company may be heartily recommended to employers of labor in the electrical field.

RICE'S PATENT FRICTION CLUTCH PULLEY.

The friction clutch pulley herewith illustrated, was invented by A. C. Rice, superintendent of the extensive works of the Stilwell & Bierce M'f'g. Co., Dayton, Ohio. The engraving represents one of the pulleys in perspective, attached to a shaft and thrown into gear. The clutch is shifted in and out by means of an upright shaft terminating in a pinion which engages in a rack cut in the side of the shifter sleeve extension. This shaft is provided with a hand wheel, and may be extended so as to operate the clutch from any floor above or below. The ordinary shifter fork and lever can be used, and will be provided if preferred.

The clutch is provided with four metal friction shoes, which are simultaneously operated by the four crooked shifter arms. Each of these shifter arms is fulcrumed on an eccentric bolt, the end of which only is seen. The centre of each friction shoe is out of centre with its corresponding eccentric bolt, the effect of which is, that when the friction shoe is thrown out against the friction rim, the shoe acts as a wedge, increasing the friction of the two surfaces, just in proportion as the load is increased, thus effectually preventing all slip. Each shifter arm is provided with an anti-friction roll running in the inclined slots in the shifter sleeve, which makes it easy to operate. These inclined slots terminate at both ends in straight slots parallel with the shaft, which serve to lock the shifter arms and prevent all friction whatever on the shifter sleeve caused by centrifugal force when running, and consequently all tendency to throw in or out.



Rice's Friction Clutch Pulley.

This clutch is positive in action, very powerful in grip, perfectly balanced, does not throw out oil when running, is entirely free from clap trap attachments, and will be found durable and satisfactory in operation.

JAMES J. SMYTH & CO., OGDEN, UTAH.

The above pushing concern has just secured a franchise for a messenger and fire alarm system, for which it will use about 6 miles of Shield Brand wire. The system to be used has not yet been selected. Mr. Smyth writes us that he has just been wiring the new Opera House for 800 lights, using nothing but Okonite wire. He has other wiring work on hand, and says he would welcome a partner with about $2,000 capital and some experience to open up a first-class wiring house, and run the messenger system. Ogden, now a city of 20,000 inhabitants, has two electric light plants. The Citizens' Electric Light Co. has just completed a Westinghouse alternating plant of 2,000 incandescents and 50 arcs. The Ogden City Electric Light & Gas Co. is running 50 Brush arcs and 750 Heisler incandescents. It is also putting in a Thomson-Houston 1,500 light alternating plant, together with two 50 light Thomson-Houston arc machines.

Meadville, Pa.—The People's Incandescent Electric Light, Heat and Power Company has elected for the ensuing year the following officers: Dr. Cyrus See, president; Charles Fahr, vice-president; John Reitze, Jr., treasurer; F. R. Shryock, secretary.

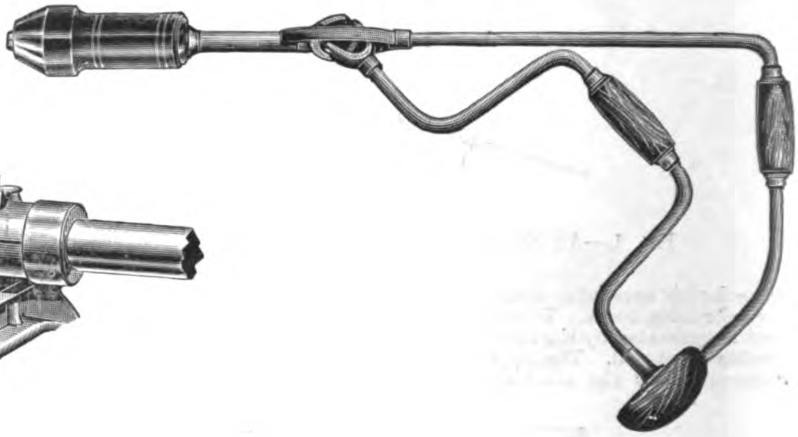
A NATIONAL ELECTRIC MANUFACTURING CO.'S PLANT.

The stockholders of the Centralia Electric Light & Power Co. held a meeting at the office of Capt. S. L. Dwight last week and elected a board of directors and officers. The following five gentlemen were elected directors:—S. L. Dwight, J. J. Wetmore, H. T. Cunningham, Jas. Benson, T. J. Wilson. The board organized by electing T. J. Wilson, president; S. L. Dwight, secretary and treasurer; James Benson, superintendent. It is the intention to turn on the light at once. They will start with 240 paying lamps, and have orders for about 140 more to be put in right away. The plant is alternating incandescent, put in by the National Electric M'f'g. Co., of Eau Claire, Wis.

THE AMIDON CORNER BRACE.

In electrical construction, great difficulty is often experienced on account of the necessity of boring in corners, and close to the floor or ceiling.

The Amidon corner brace, which is illustrated in the accompanying engraving, was designed especially to meet this difficulty. The brace, as will be seen, works at an angle of forty-five degrees to the bit, by means of a universal joint, and the pressure is applied directly through the arm, instead of through the sweep. It performs its work quickly, with a minimum expenditure of labor, and, owing to the straight arm just mentioned, can be used with advantage in the clear, as an ordinary brace. The tool is made by C. H. Amidon, 1451 Niagara street, Buffalo, N. Y.

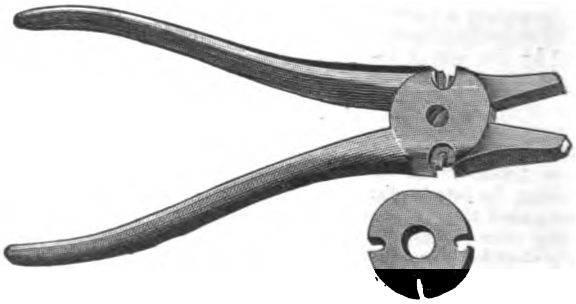


Amidon Corner Brace.

THE ACME PLIER.

The importance of serviceable pliers for linemen and others engaged in electrical construction has resulted in the expenditure of considerable ingenuity upon improvements in these very necessary implements.

The accompanying illustration shows the Acme plier and wire cutter, manufactured by the Higganum Hardware Co., of Higganum, Ct. The leading feature of these pliers consists in the fact that the cutters are interchangeable, so that when one wears out, or becomes dull, it may be replaced at a trifling expense, obviating the necessity of purchasing a new pair of pliers. The substitution of fresh cutters can be effected with ease and at a trifling expense.



The Acme Plier.

Concord, N. H.—The Concord Horse Railroad Company at its annual meeting elected the following directors: Moses Humphrey, Howard A. Dodge, Paul R. Holden, George A. Cummings, John H. Albin, Dexter Richards, George W. Abbott.

THE WILLIAMS SWITCH BOARD.

In The Electrical Engineer of June 11, 1890, appeared a sketch of the life of Mr. Charles Williams, Jr., whose untiring perseverance did so much toward perfecting the telephone, and whose switch boards, as early as 1877, and for nearly ten years after that date, were used by most of the telephone stations in the country.

The accompanying illustrations show two styles of the Williams switch board, which have remained standards for excellence and utility, and are still in service all over New England, as well as in other states.

The switch board shown in Fig. 1 is a cord board, with annunciator drops and automatic switches and keys for calling and connecting the telephone to subscribers' circuits. In this board the movements necessary to connect and disconnect subscribers are reduced to a minimum, and it is believed to be the simplest and most expeditious in manipulation of any board yet devised. It is in practical operation in about half the exchanges in the United States, and is the standard board adopted in Europe as well as in America for small exchanges. The board shown is for 50 lines and is 16½ inches wide, 18 inches deep, and stands 62 inches from the floor.

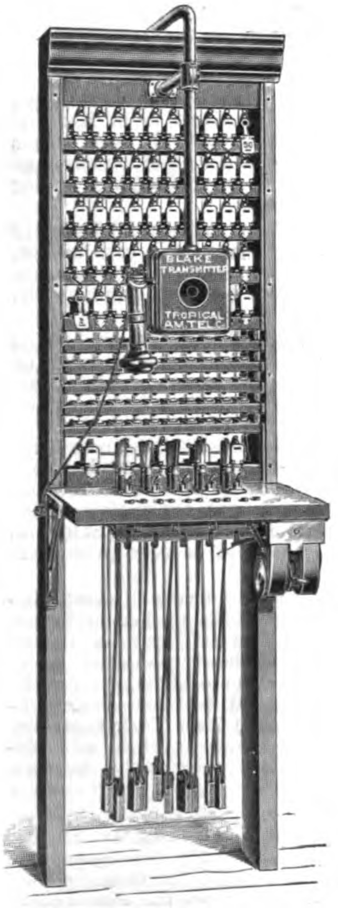


Fig. 1.—The Williams Cord Switch Board.

The peg board, Fig. 2, is arranged for table operators, and has met with great favor where there are only 300 or 400 subscribers in the system. These boards are lettered 1A, 2B, 3C, etc., and can be placed side by side, connecting each table with the next. They are 61 inches high on their stands, 37 inches wide, and 27 inches deep from front to rear.

The drop used in these boards is the Hynes or Williams drop, the use of which is controlled by the Tropical American Telephone Co., of Boston, Mass.

AN ELECTRIC LIGHT ON WHEELS.

Manager Charles Atkins, of the Council Bluffs Telephone Exchange, has invented a novel means of distributing incandescent electric light in various parts of his office. His invention was created by the necessity of having a strong light for examining the delicate points of the switch board, and consists of a portable car that travels on two copper wires that are strung the full length of the room about four inches from the ceiling, and just back of the switch board. Both wires are connected through a fuse box with the main incandescent circuit. The car is a small wooden affair with four metallic wheels, two of which rest on each wire. A flexible cord, having two electric conductors, passes up through the centre of the car, and each of the conductors is soldered to the frame. The lamp socket is attached to the other end of the double cord in the usual manner. With this arrangement the car can be run along the wires with ease, carrying the light wherever needed.

BALL ENGINES IN PHILADELPHIA.

Two 100 horse-power tandem compound engines manufactured by the Ball Engine Company, of Erie, Pennsylvania, are furnishing power for the new station of the Columbia avenue Electric Light Company, located on Columbia avenue, Philadelphia. Mr. J. W. Parker, agent of the Ball Engine Company, placed these engines.

WALL SOCKETS IN THE WEST.

That the Western people are appreciating the advantages of electric lighting more and more is shown by the steadily growing percentage of the electric trade which comes to Eastern houses from the West. As this Western trade is often most quickly and satisfactorily handled from a point near the Mississippi, many firms have established Western agencies. Hence the Bryant Electric Co. is having its switches and sockets pushed in the West by George Cutter, the well-known electric specialty dealer, of Chicago. As soon as the company found that their new sockets were proven by practical tests to be at least the equal of any on the market, they started to make wall sockets on the same plan. These were mounted on such neat wood or porcelain bases and so well made throughout that they made even a greater hit than the regular key socket. As the result, Mr. George Cutter has been getting orders for them faster than they could be made, and he expects to sell many thousands of them this spring.

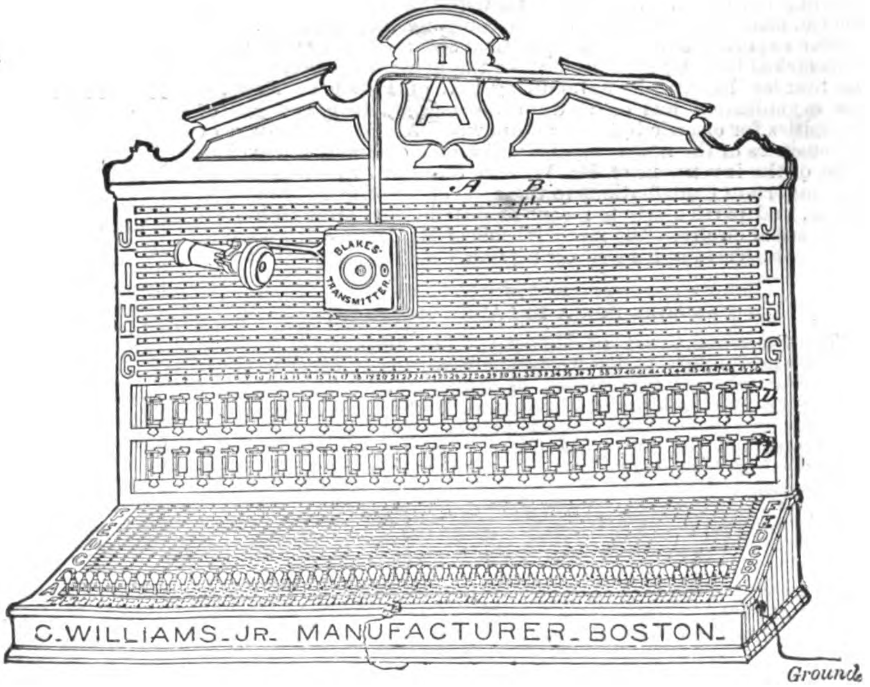

Fig. 2.—The Williams Peg Switch Board.

Mr. James Gamble is a pioneer electrician on the Pacific Slope. He is now busily engaged in electric railroading, and has fought the battle of the trolley very successfully in the newspapers. The fact that he is so active in electric railway work derives emphasis from his association with cable work, as he was at one time president of the National Cable Co.

Schenectady, N. Y.—Mr. J. H. Delany, of the Edison Machine Works, and son of Mr. P. B. Delany, the inventor, was married recently to Miss May Macdonald, daughter of Dr. George Macdonald, of Schenectady.

"K. K.' WIRE AND THE STORM.

The following is an extract from a letter received from The Bristol Electric Light and Power Co., Bristol, Pa., January 29th, 1891:

MESSRS. HOLMES, BOOTH & HAYDENS.
NEW YORK.

Gentlemen: All our K. K. lines withstood the storm of Saturday night. In two instances telephone wires rested across the mains without short circuiting us, and a number of such wires depended from our lines to the ground, without showing any ground at the station.

In fact, we have never had a break or ground on your wire, and hope that we never may.

Very truly yours,
[Signed] CHAS. E. SCOTT, Treas.

"HERCULES" TROLLEY WIRE.

The Electrical Supply Co., Chicago, report an increasing demand for Hercules trolley wire. This wire is specially drawn for electric railway work, and has in an unusual degree the particular qualities necessary to a satisfactory trolley wire. The company's facilities for furnishing it in any quantity are unexcelled, and the excellence of the wire is a recognized fact.

MR. HENRY HINE.—A NEW ENTERPRISE.

Mr. Henry Hine, district agent of the Westinghouse Electric Co., at New York, has resigned, to take effect February 15. Mr. Hine, who has been connected with the United States Electric Lighting Co. from its inception, and with the Westinghouse Electric Co. since its lease of the former company, and has had an extensive experience in both the practical and the commercial fields of electrical industry, will undertake the general managership of the Stanley Electric Manufacturing Co., of Pittsfield, Mass., a new organization just effected for the manufacture and sale of specialties for electric lighting and power. A principal feature of the business of the new company will be the commercial development of the inventions of Mr. William Stanley, Jr., whose useful and important contributions to the arts of electric lighting and power, and particularly to means of distribution, are well known in electrical circles. The many friends of Mr. Hine will wish him abundant success in his new connection.

DAMAGES FOR A DELAYED MESSAGE.

The Supreme Court of Mississippi has affirmed a decision against the Western Union Telegraph Company in favor of C. H. Alexander whereby he receives, as damages and interest, $2,500.

In 1886 Alexander sent a telegram to real estate dealers in Chattanooga to purchase certain property for him. The telegram was delayed thirty-six hours, and when delivered the property had been sold. Alexander then brought suit against the company. The company gained the case twice in the Circuit Court.

NEW ENGLAND TRADE NOTES.

THE CORLISS STEAM ENGINE CO., of Providence, R. I., are at present engaged in installing a compound condensing engine in the station of the United Electric Light Co., at Springfield, Mass. The cylinders are 22 inch and 44 inch by 5 feet stroke, and the pulley is 25 feet in diameter by 66 inch face, and weighs about 66,000 pounds. This is the second engine installed by the Corliss Engine Co. for the United Electric Light Co. There is undoubtedly a large and growing demand for high class compound Corliss engines, and judging by a visit to the factory of the Corlis's Co., at Providence, this company appears to be getting its share of the work.

NIGHTINGALE AND CHILDS, of Boston, report a very large and increasing demand for their magnesia covering, both for steam pipes in electric light stations, and for covering the cylinders and pipe connections of steam engines for electric purposes. Among their recent orders are the following: Covering for steam piping for the Ames Building in Boston; the Walworth Light and Power Co., Boston; New Bedford Gas Light Co., New Bedford, Mass; Worcester Electric Light Co., Worcester, Mass; Nashua Light, Heat and Power Co., Nashua, N. H.; Pittsfield Electric Light Co., Pittsfield, Mass; Lynn Gas and Electric Co., Lynn, Mass; Edison Electric Illuminating Co., of Boston; United Electric Light Co., Springfield, Mass., and several orders from the Thomson-Houston Electric Co., of Boston. The Corliss Steam Engine Co., of Providence, use large quantities of magnesia for covering the cylinders, heaters and connections of their engines, and other engine companies are rapidly adopting it.

THE JOHN BECKER MANUFACTURING CO., of Boston, are having a large sale at present of their name plates used for putting on engines, dynamos, motors and all kinds of machinery. This company are peculiarly well adapted for manufacturing these light castings, and have earned quite an enviable reputation for themselves on the attractive appearance of their goods. Mr. Becker has also made quite a success of his new vertical miller, and is filling orders for them as fast as he can manufacture them.

MR. STEPHEN E. BARTON, president of the Electric Mutual Insurance Co., of Boston, is about completing an arrangement with the American Casualty Insurance and Security Co., of Baltimore, Md., whereby he is prepared to issue insurance to all owners of electric light, power and railway plants covering all damage to property or person (whether employees or others) by reason of explosion of boilers; also any injury to employees or others from electrical or other accidents anywhere in the station or outside circuits; in fact to cover the liability of any electrical company for accident or injury to any person or animal.

Very unique and improved forms of policies, much more liberal, it is claimed, than any heretofore issued, are being offered by this company. Mr. Barton also issues policies in large stock companies, which he represents, covering all classes of electrical property while in transit from factories and work-shops to any part of the United States or British Provinces, and during the installation of plants, either central or isolated.

WESTERN TRADE NOTES.

MR. THOS. J. CREAGHEAD, formerly of the Westinghouse Co., of Chicago, is now doing an extensive business from his new offices, 37 and 38 Mitchell building, Cincinnati, O., where he is paying attention to consulting and constructing electrical engineering work. He is one of those brainy, hustling young electricians who always command success.

MR. G. A. EDWARD KOHLER, the Western representative of The Eddy Electric Motor Company, has, during the past month, sold 26 horse-power of machines of various sizes. Such a trade as this speaks strongly for the merits of the motor and for Mr. Kohler's abilities in securing business.

THE CHAS. MUNSON BELTING CO., of Chicago, have presented their many friends and patrons with a handsomely gotten-up calendar. The upper half is taken up with a very excellent colored engraving of some mammoth belts in progress of manufactures showing the machinery used, which is of special design and is one of the important factors that render these belts so excellent. In the right hand corner is their well-known Eagle trade-mark, and beneath are the letters O. K., which all who have used this belting say is eminently right and proper as expressive of the excellence of the belts. The lower half is devoted to the calendar, which is printed in handsome, bold type and is very prominent and striking.

THE WESTERN ELECTRIC CO. have issued a new and most comprehensive catalogue of their annunciators, bells, pushes, and other house goods. It is very handsomely illustrated, with a concise and clear description of each article, and should be in the hands of all who handle supplies of this kind. Some striking novelties in alarm clocks, etc., are contained in it, and the back cover is devoted to illustrations of their Chicago and New York factories, stupendous in their size and completeness, to say nothing of architectural elegance, and showing the vast character of the business handled by the Western Electric Co. and the enormous growth of the electrical industry.

MR. WM. H. MCKINLOCK, president of the Central Electric Company, met with quite a painful accident a few days ago, which confined him to his room several days. In running for a train he stumbled and was thrown headlong into the street; but, fortunately, escaped anything more serious than a sprained ankle. We are happy to be able to say that Mr. McKinlock has so far recovered as to resume his duties, though he still "favors" that ankle.

THE HAWKEYE ELECTRIC MFG. CO., of Davenport, Ia., manufacturers of the Thone system of arc and incandescent lighting, are preparing to place upon the market some new lines of apparatus of very high commercial efficiency and first-class workmanship. Their factory is pushed to its fullest capacity.

THE DAVENPORT FOUNDRY AND MACHINE CO., of Davenport, Ia., are about to largely increase their facilities for the manufacture of the well known Meyer engines, which are noted for their close regulation, high economy and small cost for repairs. Mr. Meyer has recently brought out an improved governor which gives the most satisfactory results.

MR. A. H. ZENNER, of Omaha, Neb., is now a special agent for the Electrical Supply Co., Chicago, looking after the sale of their goods in Iowa, Neb., Kan., and So. Dak.

THE
Electrical Engineer.

VOL. XI. FEBRUARY 18, 1891. No. 146.

ELECTRICAL ENGINEERING AT COLUMBIA COLLEGE, NEW YORK.

ONE of the most interesting and striking features of modern educational work is the extent to which science has succeeded in winning a place for itself in every programme and curriculum. In fact, there is to be heard occasionally and in some quarters the assertion that at more than one seat of learning science has become the chief and favored study, so that the rightful claims of the older branches are overlooked and neglected in the desire to gratify the craving for physical research and for instruction in the great modern engineering professions. Perhaps this is true, but it is not to be denied that in thus shaping their aims and plans, our colleges and universities are but responsive to an urgent, insistent demand for teaching of this character—a demand that is none the weaker because it has long been disregarded and hushed down where it should first have met with a kindly and sympathetic response. It certainly cannot but be a cause of rejoicing to all concerned in the promotion of the arts and sciences that the day has at last arrived when the genius of the engineer is free to find its training and its career, no matter what the peculiar bent or enthusiasm may be.

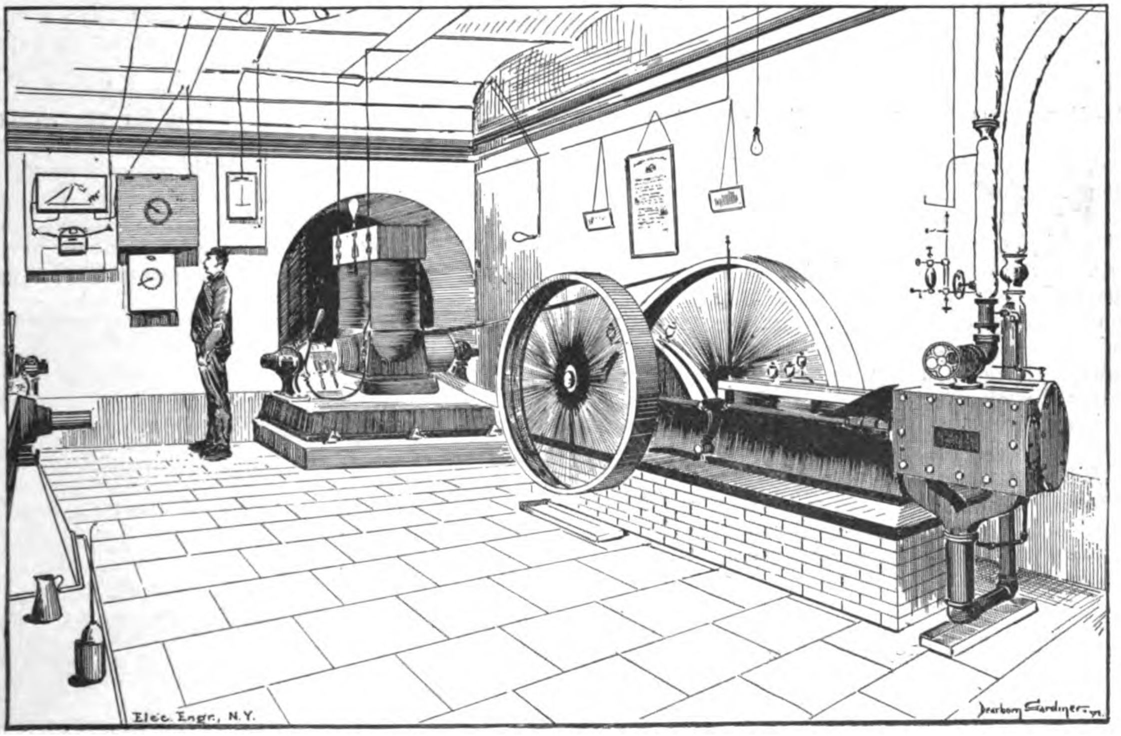

FIG. 1.—THE DYNAMO ROOM, COLUMBIA COLLEGE, N. Y.

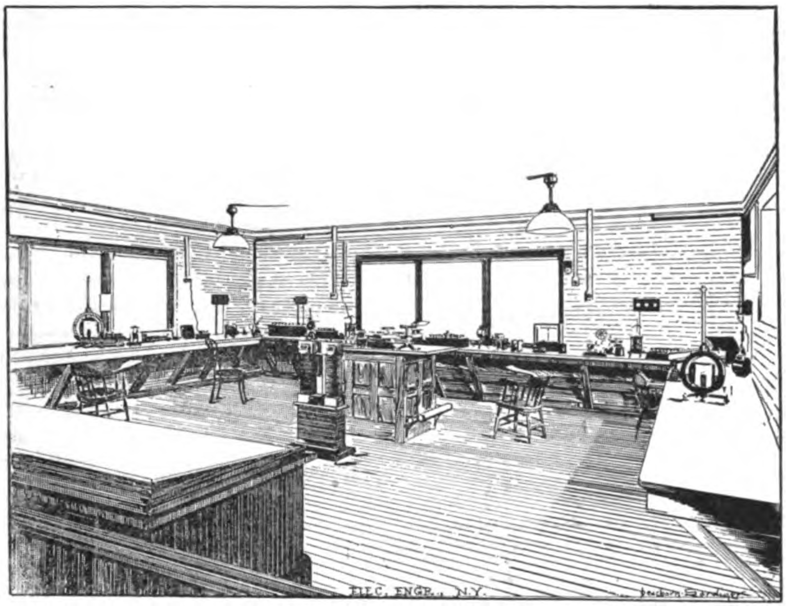
As might have been expected, from its traditions, Columbia College was early impressed with the desirability of promoting scientific research on one hand and engineering on the other; and in due course its officers found themselves debating the propriety of so great an innovation as a course in electrical engineering The decision, arrived at promptly but without precipitancy, was that which might have been expected; and two years ago such a course was incorporated in the system of instruction and the degree of electrical engineer was added to the more familiar ones that the college grants.

Surely, if anywhere, there is encouragement in New York for the electrical student. The city is a centre for electrical enterprise and manufacture, and within its limits exist electrical installations unsurpassed in size, importance and value. Here, if anywhere, the latest electrical practice may be seen and criticised, and here, too, every new theory or investigation reports itself for approval or condemnation. The loss that the student may suffer through the varying distractions of a great city is more than compensated for in the stimulus he derives from actual contact with the throbbing realities of the profession he is soon to adopt. We need not wonder that the electrical course at Columbia has already proved a great success, and that the facilities offered draw hither aspiring youth anxious to acquire the engineering principles of the new art.

The plan resorted to by the government of the college was to establish a post-graduate course, the idea being that an undergraduate course, with numerous, untrained students, would require much space and many instructors. The post-graduate course implies necessarily a comparatively smaller number of students, and the entire absence of elementary instruction and disciplinary supervision. The course as established with this conception of its aim, covers two full years, and the requirements for admission to it are such that all preparatory studies, such as mathematics, physics, chemistry, mechanics, languages and drawing, necessary for grasping advantageously the whole subject of electricity, have been gone through. Experience shows that a student well grounded in these is the best qualified to make rapid and substantial progress in electrical work, whereas one lacking in the elements of preparation inflicts a two-fold loss, namely, on himself and on his preceptor.



ELEC. ENGR., N.Y.

FIG. 2.—ELECTRICAL LABORATORY, COLUMBIA COLLEGE, N. Y.

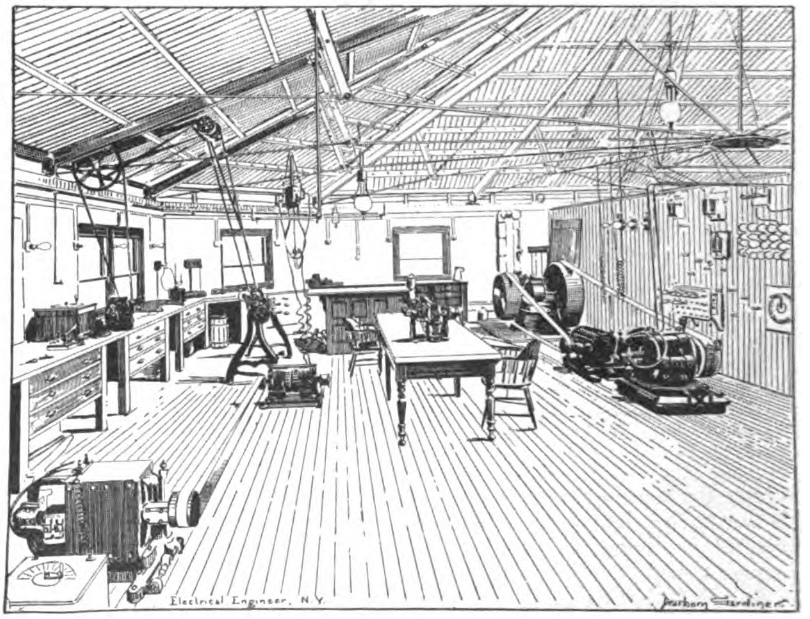
The course, then, is almost entirely electrical, the more special reasons for this being stated by Prof. Crocker himself in the short article on the subject appearing in this issue. Such subjects, however, as mechanical engineering, and drawing, as applied to electricity, are included, as a necessary part of electrical engineering. The subject of electricity is taken up from the very beginning, with the assumption that the student knows nothing about it; and it would often be better if such were the case, nothing being more prejudicial to the acquisition of true knowledge than well-grounded misinformation. The instruction is carried along on three parallel lines. The first relates to the scientific and theoretical principles upon which the practical applications are based. The second deals with applied electricity, covering the practical facts, the apparatus and the "systems" used in and constituting the electrical art and work of the day. These first two lines are covered by lectures and recitations, the standard text books being used as far as possible as a basis only, it being the fact in electricity more perhaps than in any other branch, that the books are wanting in the fresh, vital examples which the instructor must suppply in order to complete the course and to give it character, meaning and utility. The third parallel line consists in practical laboratory work in electrical measurements of all kinds, and in workshop practice, as well as the testing of dynamos, motors, lamps and other electrical apparatus of all kinds. These three parallel lines of study are meant to advance, *pari passu*, so that at every stage theory and practice explain each other, and the principles enunciated are illustrated and driven home by the actual handling of the apparatus itself.

In addition to the regular examinations at the end of each term covering the term's work, a final examination is held that necessarily embraces the work of the whole period of two years. If it is passed satisfactorily, and a creditable graduation thesis is presented, the student receives the degree of Electrical Engineer, which is fully equal in rank and significance to that of Civil Engineer.

In starting the course, the College provided, and has since added thereto, a generous equipment of apparatus, inclusive of testing instruments of almost every kind. As far as possible these instruments are different, duplication being avoided, and preference has been given to instruments of American manufacture, or those most used in American plants and stations. This laboratory is shown in Fig. 2.

In Fig. 1 is shown the College electric lighting plant, consisting of two Edison 500-light incandescent dynamos, driven by a Straight Line engine and an Armington & Sims, each of 50 h. p. By special order of President Low, this plant is under the care of Prof. Crocker, and, of course, is very useful as a working example of an isolated plant, while the widespread system of distribution ramifying from it makes it in many respects a good type of central station. There are underground circuits connecting various buildings and the system of wiring is quite elaborate. The lights can be run on the Edison 3-wire system from the street, a switch being provided for that connection, and, when transferred to the College plant they run on the 2-wire system. The College plant is in daily operation from 7 a. m. to 10 p. m., and the Edison street circuit is depended upon during the other hours.

Besides this plant, a complete electric light and power plant is provided for the exclusive use of the students. It is shown in Fig. 3. It consists of a 25 h. p. McIntosh & Seymour engine, a 200-light Standard Electric dynamo, and a 4-light Thomson-Houston arc machine, with a complete set of lamps, switches, &c., of all the various makes. An Eickemeyer motor of 5 h. p. is used for running small dynamos and other apparatus for experimental work and is very convenient, being much simpler and handier for the purpose than starting a steam engine. Several 1 h. p. and smaller motors are used for running lathes, grindstone, &c.



Electrical Engineer, N.Y.

FIG. 3.—ELECTRIC LIGHT AND POWER PLANT, FOR EXPERIMENTAL PURPOSES, COLUMBIA COLLEGE, N. Y.

Current, fortunately, is as abundant as water and just as freely on tap, for work at any time. At any point in the electrical laboratory, workshop, lecture room, &c., a current of 100 amperes and 115 volts can be drawn on immediately; and hence experiments of the heaviest nature can be made. One experiment was lately carried on that required current uninterruptedly for a whole week. Facilities of this kind are a great boon.

Reference might be made to many interesting features of the work done, but it will suffice to mention the 1,280-cell storage battery shown in Fig. 4. This was made by the students. The cells are of the Planté type, and are 1 inch diameter and 4 inches high, glass tubes being used. The battery is arranged in 40 rows of 32 each, with a switch for throwing them in series or in multiple. As will be seen, this compact little battery would give nearly 3,000 volts, if connected up throughout in straight series. The cells are set in paraffine, poured around them and solidified.

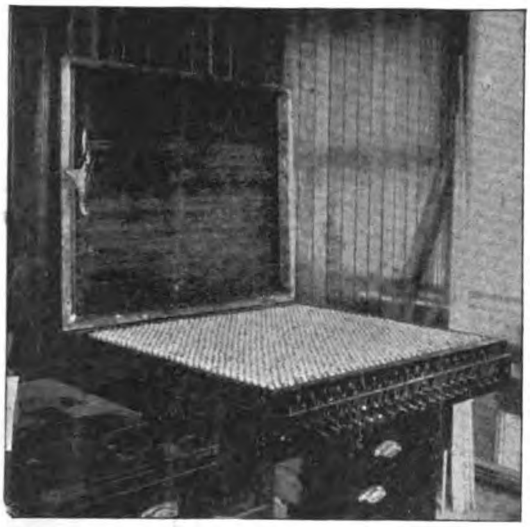


FIG. 4.—A 1280-CELL STORAGE BATTERY.

The course in electrical engineering, of which a description has been given above, is now in charge of Prof. Francis B. Crocker and Dr. M. I. Pupin, the former of whom is the instructor in electrical engineering proper, and the latter in its mathematical physics.

INFLUENCE OF THE SPARK ON RESISTANCE.

MR BRANLY has recently found that the spark of a Holtz machine or induction coil has a remarkable effect in temporarily decreasing the resistance of certain badly-conducting mixtures, such as powdered or oxidized metals, or pastes formed by immersing filings of iron, copper, or other metals in a non-conducting fluid. The effect is generally increased by connecting one or both of the sparking terminals with the substance under test, although the spark alone may be sufficient. In one case the resistance of a junction of two pieces of oxidized copper, as measured by a Wheatstone Bridge, was reduced from 80,000 ohms to 7 ohms in this way. The diminution of resistance of such conductors may last for as long as 24 hours, unless the substance is disturbed by vibrations, in which case the high resistance is restored.

AN ELECTRICAL DEVICE FOR DETERMINING THE ACCELERATION DUE TO GRAVITY.[1]

PROFESSOR F. R. BARRETT, B. A., recently exhibited a lecture room device for determining "*g*," the acceleration due to gravity, by means of a number of iron balls falling through a certain distance, one starting at the instant when its predecessor reaches its destination. This is accomplished by means of an electro-magnetic device in which the balls, falling on a key, make and break a circuit, each ball as it falls liberating the next. From the time occupied by all the balls, the time for one may be found. The apparatus is said to give fairly accurate results.

WHAT AN ELECTRICAL ENGINEER SHOULD BE.

BY

Francis B. Crocker

IT has often been stated on high authority, such as that of Sir William Thomson and Prof. W. E. Ayrton, that the electrical engineer should be largely a mechanical engineer, the proportions usually given being "nine-tenths mechanical and one-tenth electrical." This statement is frequently repeated and has been generally, if not universally accepted. The causes which have operated to produce this opinion are, first, the fact that the extraordinarily rapid development of electric light and power has prevented even reasonable care being given to the design and construction of electrical machinery, and second, the work has generally been in charge of men entirely ignorant and incompetent, or at best, of men who had received their preparation in telegraph offices or physical laboratories where strong mechanical construction is given comparatively little attention.

In the first stages of the development of any branch of industry, the men attracted to it are apt to be either amateurs, inexperienced boys, or worse yet, quacks or men who have been unsuccessful in other lines of work.

As soon, however, as sufficient time has elapsed for men to become well prepared by education or experience and the industry becomes legitimized and attracts to it a higher order of talent, then the necessary elements to give the best results will be present and a proper relation and balance will exist between them.

I consider that this now is, or very soon will be, the condition of electrical engineering, and I contend that the electrical engineer must be an *electrical specialist* and that mechanical engineering, though a necessary part of his preparation, is nevertheless merely incidental.

The simple, and what seems to me, a more than sufficient reason for this opinion is the fact that the purely electrical part of electrical engineering is being so very rapidly and extensively developed that no one person can possibly keep up thoroughly with electrical progress in its numerous branches even at the present day and no man busy in electrical work can spare the time to read even the more important electrical journals and books. In fact it now seems to be necessary for one to become a specialist in some particular branch of electrical work in order to be successful. Such being the case, it certainly is impossible for the general electrical engineer to give more than a small fraction, say one-quarter, of his time to mechanical engineering instead of the nine-tenths heretofore recommended. This is not because mechanical engineering is not of the greatest interest and importance in itself, but because a man's time and abilities are limited and *electricity* is a gigantic subject, a small part of which is probably all one human mind can master.

In order not to be misunderstood, I will state that I thoroughly realize that mechanical engineering is, and probably always will be, an essential *part* of the electrical engineer's knowledge, just as chemistry is essential to an understanding of electro-metallurgy, primary and secondary batteries, etc., but only as a preparation.

In any case the electrical engineer should be an *engineer* in the broadest and best sense, his profession being analogous to, but not identical with, that of the civil, mechanical, and mining engineers.

In conclusion, I would call attention to the fact that the mechanical weakness which arose in the early development of the dynamo and motor has now nearly passed away, and to-day the standard types of dynamo and motor are probably as well made mechanically as any other class of commercial apparatus. Moreover electrical machinery is usually remarkably simple, mechanically. Compare the number of working parts of a 50 h. p. motor with those of a corresponding steam engine and there will be found in the former about one-fifth as many oil cups, bearings, pivots, sliding surfaces, etc.

---

[1] Proceedings of The Physical Society, London.

On the other hand what is needed in the dynamo and motor to-day is improvement in the armature, commutator and brushes, and in means for avoiding sparking, burning out, etc., all of which belong to the *electrical* part of the machine and involve very difficult electrical questions. Of course first-class mechanical construction is necessary even in these parts but only as incidental to the carrying out of correct electrical principles.

In the design of a street car electric motor, which is peculiarly mechanical, although the electrical difficulties encountered have been fully as great as the mechanical, I believe that a mechanical engineering specialist should be employed just as an architect should always be called in to design a house or a plumber to put in water pipes.

THE "CAMBRIDGE" ACCUMULATOR.

In all the storage batteries now generally in use, the principle employed is the suspension of the active material in some form of leaden grid. Various forms of grid are in use, but all use the lead as a means of support for the active material, as well as forming the electrodes of the battery.

In the battery recently invented by Mr. G. E. Hatch, of Cambridge, Mass., which we illustrate in the accompanying engravings, the lead is not employed for supporting the active material, but simply as an electrode, lead being the only known substance which can be successfully and commercially used as a conductor submerged in dilute sulphuric acid. The active material, as will be seen, is supported by a porous plate, and comes as near as possible to the ideal battery of this kind, having the active material in suspension in the solution without support.

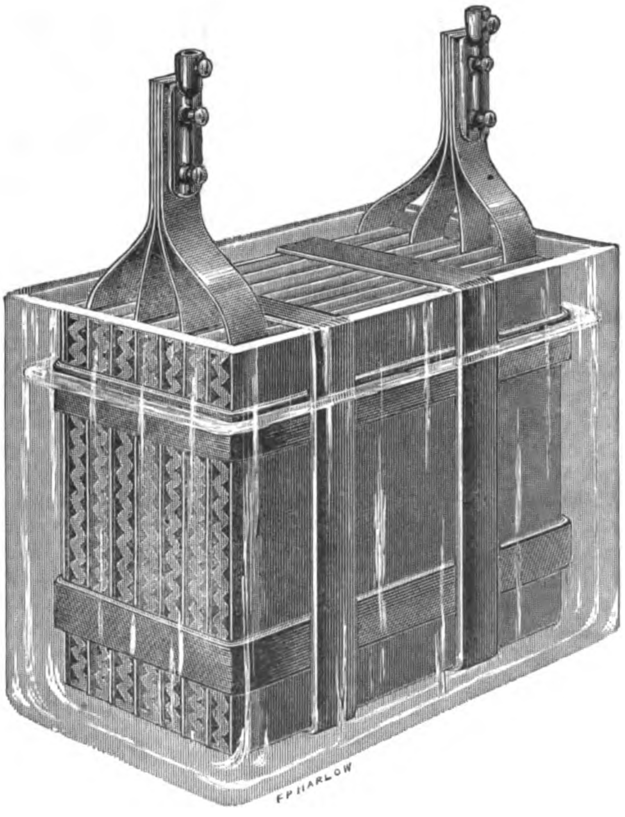

Fig. 1.—The Cambridge Storage Battery.

The fundamental principle of the Cambridge battery is a porous plate, shown distinctly in Fig. 2, which represents the battery set up before immersion. This porous plate is designed to have the greatest amount of porosity obtainable and is corrugated as shown. The active material is filled into the corrugations until quite flush and smooth, as shown by the dark black zig-zag spaces in the engraving, and the corrugated porous plate acts as a support for this material, instead of the leaden grids generally employed.

The porous plates for a 200 ampere-hour cell are each 7 inches square, ½ inch broad, and the corrugations are ¼ inch deep. It weighs, when dry, about 10 ounces, and when wet, about 15 ounces, and is thus capable of absorbing about 5 ounces of liquid. After the corrugations of the porous plate are filled with the active material, the lead conducting plate is placed alongside—the positive on one side and the negative on the other—with lugs extending upwards to the terminals. These plates are made of an alloy which is only very slightly affected by electrolytic action, and weighs about 2 pounds to the square foot.

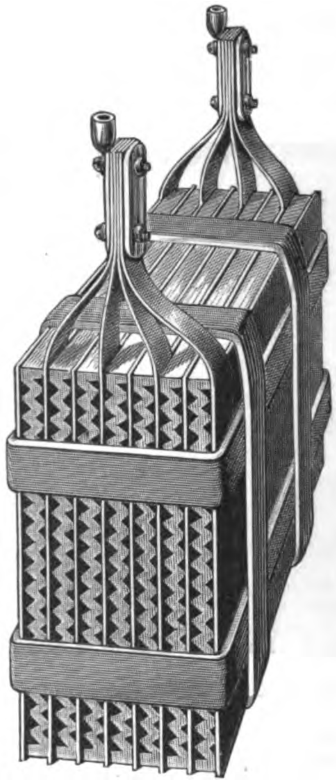

Fig. 2.—The Cambridge Storage Battery.

The 200 ampere-hour cell complete, consists of seven porous plates with the active material, and eight lead electrodes, and weighs, when dry, about 28 pounds, of which the lead electrodes weigh only 7 pounds. The whole cell complete, as shown in Fig. 1, with glass jar and liquid weighs about 35 pounds. The element consisting of the house plates, active material and lead electrodes stands 7 inches high, 7 inches deep and 4¾ inches wide, and compared with cells now in use, is claimed to have double the capacity for the same size and weight.

Among the advantages claimed for this type of storage battery are first, that owing to the construction adopted, there is no possibility of buckling of the plates, no matter how heavy the charge or discharge, and therefore an entire absence of short circuiting. The absolute control of the active material is provided for by its being shut in so that it cannot be thrown out of its place by expansion or contraction, or by jolting, if used for car service. The cell is flexible, being bound together simply by rubber bands, which allow of expansion and contraction, which occurs when the cell heats up from heavy charge or discharge.

The battery requires very little care and can be discharged, even should the glass or rubber containing jar be broken, sufficient moisture being retained in the porous plate to totally discharge the cell. The writer himself saw a number of lights actually burning, with one of the elements of the series of cells outside of any jar containing liquid, without the slightest diminution of the brilliancy of the light. The gases which are generated by electrolytic action are freed as in other cells, owing to the extreme porosity of the porous plates.

The Cambridge Accumulator, we may add, is now being introduced by the Cambridge Accumlator Co., of Boston, Mass.

THE PROPOSED ADAMS ELEVATED ELECTRIC RAILWAY SYSTEM IN CHICAGO.

Like all cities whose population is spread over a wide area, Chicago has for a long time experienced the want of a rapid transit system. It is true that it possesses even now a system of cable and horse cars probably not inferior to that of any other city of equal size, but the speed obtainable with these, even under the best conditions, does not satisfy the wants of the large majority who live at a distance from their place of occupation, and those also whose business requires a quick method of reaching the various parts of the city.

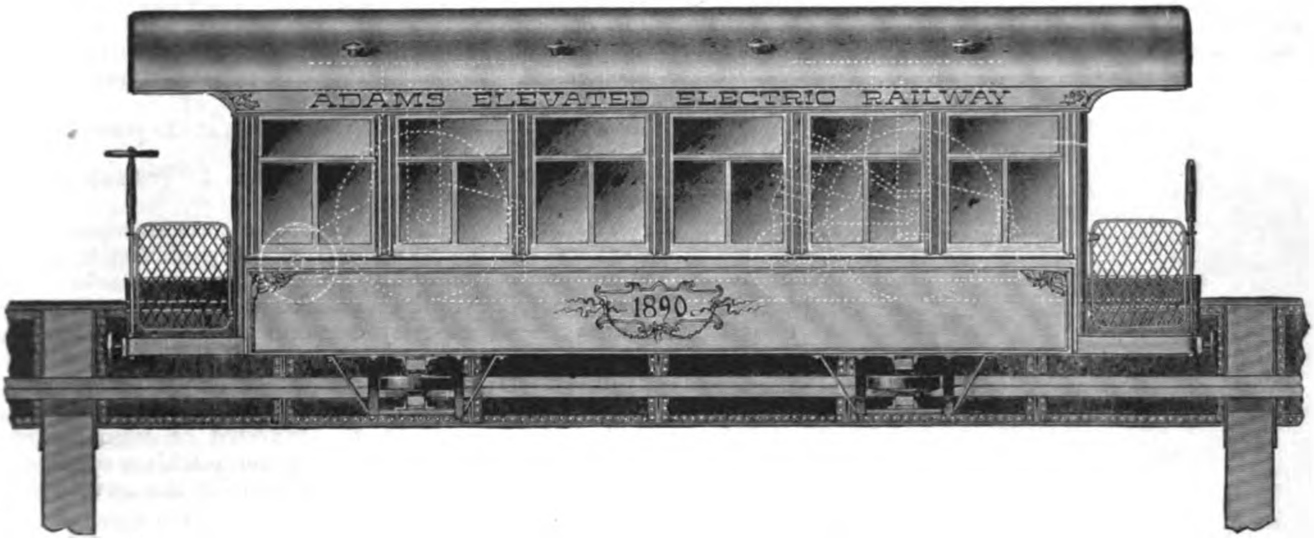

Fig. 1.—The Adams Elevated Electric Railway.—Side Elevation.

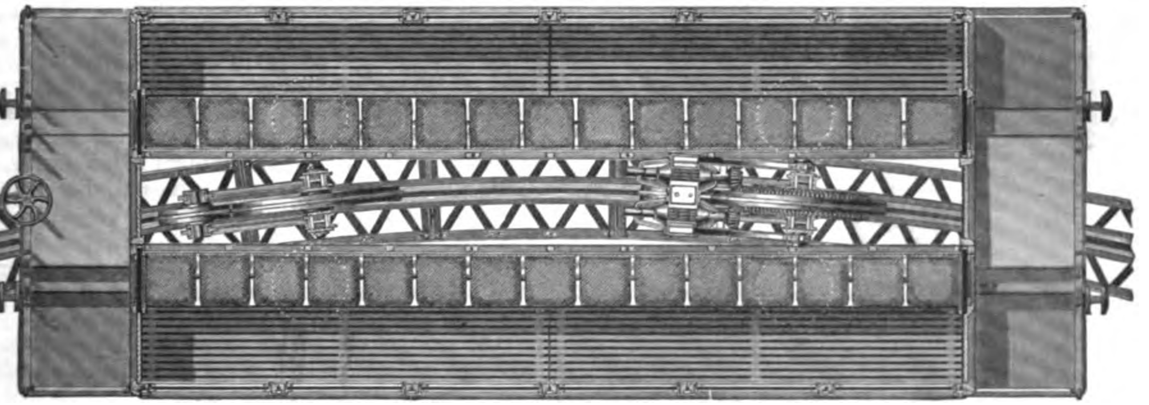

Fig. 3.—The Adams Elevated Electric Railway.—Plan View.

It is obvious that to obtain the desired speed some other method than the surface railway must be adopted, and with the great cost of an underground railway to be contended with, an elevated road is held to be at present the only solution of the problem.

Among those who have been prominent in agitating such a system for the city of Chicago is Mr. J. W. Adams, who has devoted a large share of his attention to the subject, and has elaborated a plan of construction and operation for such a road which cannot fail to attract the attention of electrical engineers.

The plan proposed by the Adams Company contemplates the erection of a single track, single column elevated railway, so as to present as little obstruction as possible to traffic and light in the streets, and the operation of the road by electricity, thus at once removing one of the principal objections to the elevated railway.

It is designed to effect the rapid and effective handling of passengers by frequent and rapidly moving single cars, and by confining entrance and exit to the opposite sides of the rear platform in charge of a gate man. The use of the single car instead of a train allows of a great reduction in time required in starting from rest to full speed, as well as in stopping at stations, so that an average speed of 20 miles per hour is confidently looked for as practical in this system.

The cars will be operated continuously in the same direction on a loop 20 miles in length, and at a distance apart of 750 feet, which is equivalent to a headway of 20½ seconds; this is considered perfectly practicable with single car units, and with the special track brakes to be employed, so that 140 cars would be in continuous operation on the circle.

The proposed construction of the elevated structure and the cars will be readily understood from the accompanying engravings.

The columns supporting the superstructure are about 14 feet in height in the clear, and set 40 feet apart, and their dimensions are 15x18 inches; they are set in concrete about 8 feet deep in the ground. The girders forming the superstruction are 3′ 8″ in height by 2′ 6″ in extreme width. The strength of the whole structure is such as to sustain a moving load of 20 tons per car including dead and live loads, and 25 per cent. added to the strains derived from the above stated loads, the sections of the main girders being proportioned accordingly. This construction has been figured on the basis of carrying a maximum capacity of 279,000 passengers per day. Each car will be provided with two 4′ 6″ drive wheels, each of which is rigidly connected to a 2 foot pilot wheel, all being made of paper. These two wheels are supported, and both swivel on the same turn-table, and adapt themselves not only to the curves, but to the slightest irregularities of the track, making the movement of the car very easy. The rail employed is of special design, having the tongue space in the centre and is rolled for this purpose, and the wheel is constructed with the flange in the centre.

Our readers will, of course, be particularly interested in the electrical arrangements to be adopted. These have been under consideration for some time by Mr. Frank B. Rae, the electrician and engineer of the Detroit Electrical Works, who has been retained as consulting electrical engineer to the road.

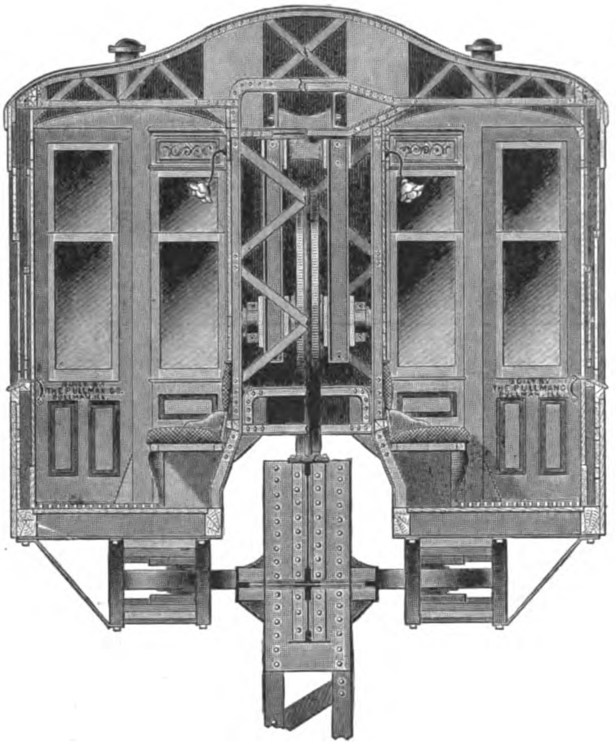

FIG. 2.—THE ADAMS ELEVATED ELECTRIC RAILWAY.—SECTIONAL VIEW.

It is proposed to equip the cars with a double field motor having two armatures and gearing, by bevelled pinion, directly to the large wheel of the truck, as shown in the plan, Fig. 3. By this construction, the power is applied equally to both sides of the wheel and end thrust upon the bearings is entirely eliminated. The electrical horse power of the motor will be normally 50 h. p., the motor being designed to develop for a short time at least 75 h. p. The ratio of reduction by the gearing will be 9 to 1 and the maximum velocity of the armatures at a car speed of 25 miles per hour will be 1,400 revolutions per minute. By the use of leatheroid and raw hide pinions upon the motor shafts and by the use of paper wheels, the noise will be reduced to a minimum.

In considering a system of 20 miles of track, the maximum number of cars that can be operated practically is determined largely by the number of stops that will be made by each car, for the reason that the time required to raise the car from its position of rest to full speed depends upon the power available to overcome inertia and this is limited to the capacity of the motor. The weight of the loaded car is taken at 20 tons and the extreme maximum power of the motor for a few seconds, when it is just reaching the maximum speed of 25 miles per hour, is 70 h. p.

In the determination of the copper required to supply power as above to 212 cars, on a basis of 1 stop in 3, it is thought that the maximum draught cannot exceed that required by two-thirds the total number of cars, each taking the average number of horse-power which is required to raise it to a speed of 25 miles per hour from rest, so that the maximum horse-power equals $\frac{2}{3} \times 212 \times 36$, or, 5088 at the wheel axle. Allowing 80 per cent. efficiency in gearing, 80 per cent. efficiency of motors and 90 per cent. in conductors, this figure becomes 8,833 electrical h. p. delivered to feeders. This would call for a weight of 2,253,450 lbs. of copper, in order that the loss shall not exceed 10 per cent. This loss is deemed both practical and economical. Reducing this copper to cost per mile, we have $\frac{2,253,460}{20} = 112,673$ lbs., which at the present market price of 19.75 cents per lb. amounts to $22,243 per mile, exclusive of erection.

The station electrical equipment would consist of 20 dynamo machines, having a capacity of 500 h. p. each, aggregating 10,000 h. p., and driven in banks of five machines from triple expansion engines of 2,500 h. p. each, with a reserve capacity of 10 to 20 per cent. above this. Each of the dynamo machines would be connected to the engines through a countershaft and clutch pulleys and so arranged mechanically and electrically that any single unit of 500 h. p. might be connected or disconnected at will; thus the number of dynamo machines operated at any time may be only that required for the service at the time.

Each car is to be lighted with incandescent lamps as follows: 1 head light, 1 rear red light, 1 rear platform light, and 12 inside lights; total, 15 lamps. Total for 212 cars, 3,180 lamps.

Each station is designed to have 10 lamps. This would give, total for 10 stations, 1,050; cars, 3,180; total, 4,230 lamps. This would call upon the power plant for additional 425 h. p. when all are in use, taking on an average 10 lights per mechanical horse-power.

As indicated above, the engines to be employed would be of 2,500 h. p. of the compound condensing type, consuming, say, 3 lbs. of low grade coal per horse-power per hour. The station is to be situated near water, so that no cost will be entailed for water. The price of slack coat at Chicago is about $2.00 per ton, delivered.

The central station expenses per day of 18 hours, with an average load 8,000 h. p. are assumed to be as follows:

Coal	$432.00
3 engineers at $4.00	12.00
3 engineers at $3.00	9.00
4 firemen at $2.00	8.00
2 electricians at $4.00	8.00
2 asst. electricians at $3.00	6.00
Oil, waste, etc	10.00
Total	$485.00

It will, of course, be understood that these electrical estimates are merely preliminary in their nature and will no doubt be subject to more or less modification when the details to be adopted are thoroughly worked out. The project is certainly a feasible one and it is to be hoped that Chicago will afford the opportunity of demonstrating the undoubted economy which can be effected by electric traction.

THE RIKER SLOW SPEED BIPOLAR MOTOR.

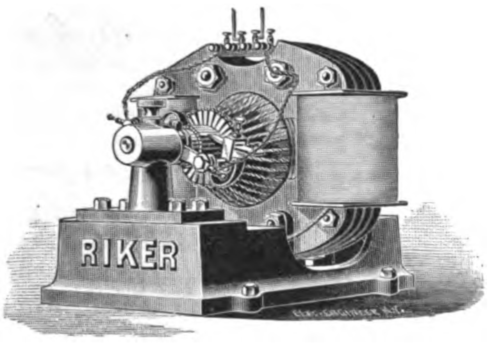
BY

Andrew L. Riker.

Most low speed motors manufactured are of 5 h. p. or upwards, because of the loss of efficiency in small low speed bipolar machines or of the impracticability in winding a multipolar machine of small horse power.

After a considerable time spent in experimenting and testing, the writer has succeeded in producing a bipolar slow speed machine at moderate cost and of high efficiency.

By those thoroughly acquainted with the changes made in dynamo electric machines or motors, it will be remembered that the writer was one of the first to use a laminated field, and the first to use and continue in the use of a toothed armature. By a constant study of its peculiarities and a thorough acquaintance with its workings, during this time, in high speed machines, he has at last been enabled, by using it in connection with a special winding of his own design, to make a slow speed machine from ½ to 5 h. p. of very high efficiency and simplicity of construction, which is illustrated in the accompanying engraving.



The Riker Two-Pole Slow Speed Motor.

The machine has its field magnets built up of laminated iron bolted together and is fixed to the base by gun-metal brackets, so that no magnetic leakage occurs. The ½ h. p. machine illustrated is designed to run at 650 revolutions per minute, at which speed it develops an efficiency of over 70 per cent. The motor weighs less than 100 pounds and the shunt field takes about 30 watts to energize it, its resistance being 280 ohms. The writer proposes to make a series of tests on the machine, which will be duly reported.

THE MOSHER ARC LAMP FOR INCANDESCENT CIRCUITS.

One of the objections that has been raised against the arc lamp is the uncertainty of its action when used upon incandescent circuits, thereby entailing the employment of a separate circuit when a few arc lamps are used in conjunction with incandescent lights. Several forms of arc lamp, designed to meet this want, have been used in considerable quantities, being directly connected upon the incandescent mains with the intervention of a metallic resistance or incandescent lamps in series, to maintain steadiness in the arc lamp, and prevent flickering on the incandescent lamps, due to the feeding of the arc lamp carbons.

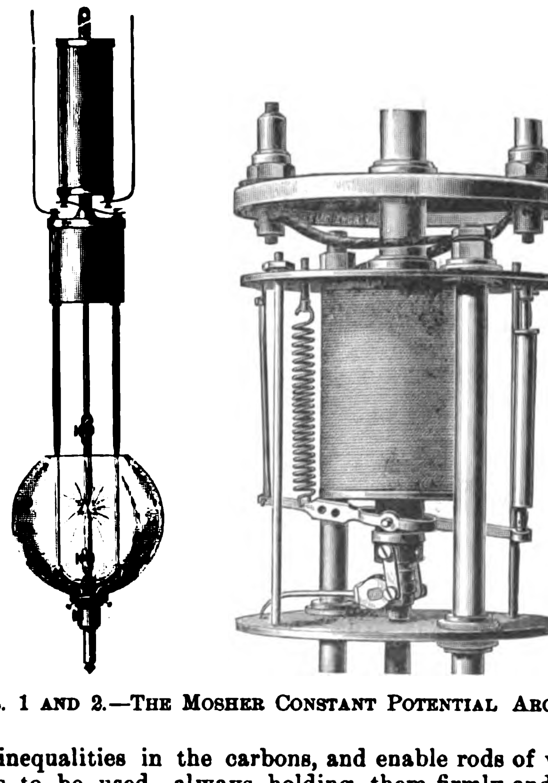
The latest lamp designed for this purpose is the Mosher arc lamp, for which are claimed important and highly advantageous improvements and modifications, and it is said to be giving satisfaction wherever introduced. The lamp is shown in Fig. 1 of the accompanying illustrations, and is of remarkably neat and simple design. It is made in brass, nickel or iron, and is adapted to burn either singly, or in series.

One of the novel features of this lamp is the employment of carbon resistance as the regulating factor. This is simple and capable of the most exact adjustment, and is one of the reasons that the lamps give such a perfectly steady light, and such excellent results in practice. The carbon resistance rods are arranged in series with the lamp, and, if desired, can be dispensed with, incandescent lamps being substituted. They are contained in a brass case placed above the working mechanism of the lamp, and perforated for ventilation.

The amount of current utilized is regulated by varying the resistance; the fewer carbons in the rheostat connected in circuit, the more current absorbed, and vice versa. The resistance is varied with the greatest facility by sliding one or more of the inner clamps surrounding the carbon rods upwards towards the upper porcelain disc, between which and a similar disc at the bottom, the carbon rods are supported. Each clamp moved from the lower to the upper disc cuts out two carbons. There are 39 carbons in the rheostat, which is adjusted to 110 volts and 4½ amperes. By cutting out five or six carbons, the current will be increased about two amperes.

The working mechanism of the lamp, shown in Fig. 2, consists of a solenoidal magnet with a hollow core, through which the upper carbon holder passes. The action of the current on the magnet operates a lever and clamping device. One end of the lever is furnished with a dash pot which can be filled with glycerine or oil, and at the other is a spring having at the top a screw, by means of which the length of the arc can be effectively and instantaneously regulated.

The carbon clamps at the ends of the rods are of novel and ingenious construction. They adjust themselves to all inequalities in the carbons, and enable rods of various sizes to be used, always holding them firmly and maintaining the points directly in line. The lower carbon holder is furnished with a ball joint attachment, which is regulated by means of a screw at the lower point of the lamp.



Figs. 1 and 2.—The Mosher Constant Potential Arc Lamp.

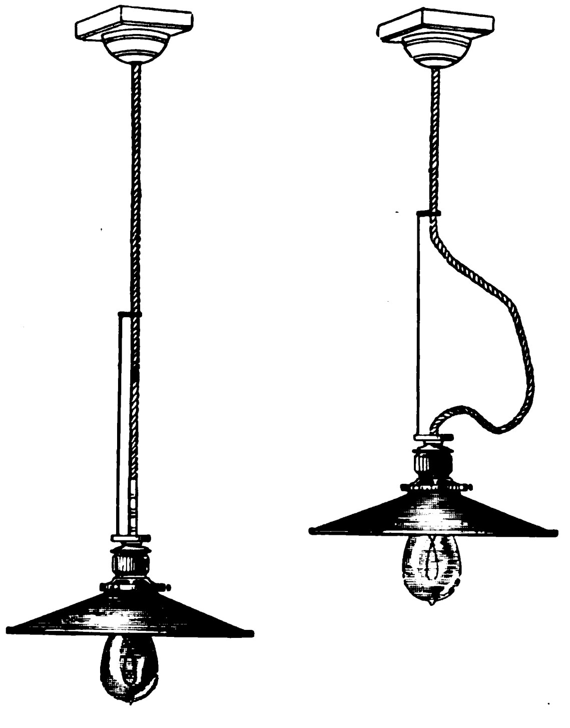
Recent tests made by high authorities have shown the lamp to work very smoothly with a silent arc and no flickering, giving a steady and brilliant light. The simplicity of the entire construction, the ease of adjustment, and the economical and perfect operation will, it is believed by the makers, at once commend this lamp to central station men, and all those who desire to use arc lamps upon incandescent circuits.

SCHENCK'S CORD ADJUSTER FOR SUSPENDED INCANDESCENT LAMPS.

The percentage of incandescent lamps broken has been found to be even greater than that due to failure on account of the exhaustion of the filament, and any device insuring safety in this particular is deserving of consideration.

Mr. Unico H. W. Schenck, the well-known inventor has invented a very simple and complete device to prevent breakage. It operates by raising the lamps to any desired height, when suspended from the ceiling by flexible cords, and is therefore particularly adapted to factories. It has been ascertained that numbers of lamps are broken in factories and machine shops, by flying clips; by the careless use of files, hammers, and other hand tools; and by pieces of iron, wood, etc., carried upon the shoulders of the men; and all because the lamps are not elevated beyond danger from such causes when not in use.

The device will be clearly understood by reference to the accompanying illustrations, where Figs. 1 and 2 show it in operation. It consists of a wire rod one end of which is rigidly attached to the lamp socket and the other fashioned into a goose-necked loop, shown in Fig. 3, through which the flexible cord passes.

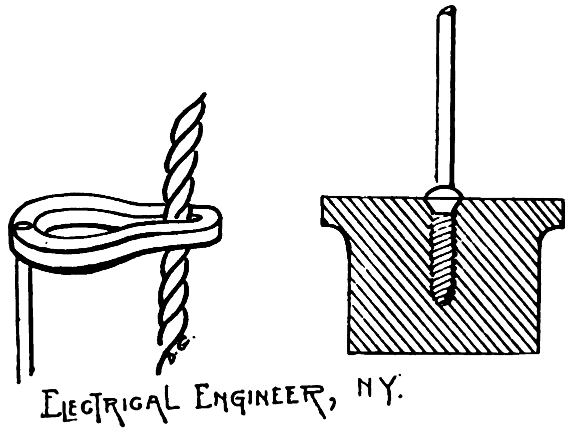


Figs. 1 and 2.—Schenck's Cord Adjuster For Pendant Lamps.

Where the lamp has a brass socket, as shown in Figs. 1 and 2, the rod is provided with a clamp at its lower end. When, however, a wooden socket is used, as in Fig. 4, the rod is simply screwed into the centre hole that is formed in the process of manufacture. Thus the device may be readily attached to the lamp without the use of screws or tools of any kind.

The raising of the lamp is effected by simply allowing the cord to run through the large end of the loop in the rod, and when the proper height is reached, catching it in the small end, which binds sufficiently to sustain the weight of the lamp.

It will be seen that this can be done with one hand. Such a device recommends itself for prompt and widespread introduction, and will do much to enhance the reputation of the incandescent lamp for durability and longevity.



Figs. 3 and 4.—Schenck's Cord Adjuster For Pendant Lamps.

LOCATING FAULTS IN UNDERGROUND CABLES.

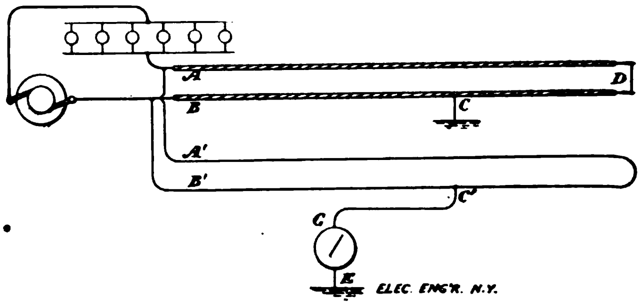
BY

R. J. Burt

Every central station manager knows how difficult it is to locate a fault or ground in an underground cable of large section and low resistance, especially when the resistance from one end of the cable to the fault is almost negligible in comparison with that of the fault. The following is a simple method used with great success by the writer in the Thomson-Houston central station of the "Electra" Compania General de Electricidad, in Bilbao, Spain. It adapts itself for locating faults more especially in feeders or simple lengths of cable without branches.

Supposing one of a set of cables, the plus, minus, or neutral, all of equal section, has a fault or ground, and one of the other two still remains perfect; then by joining the faulty cable to the good one at the further end, usually in a distributing box or junction box, a current can be sent through the cables, and we have in the station the two ends between which there is a considerable difference of potential due to the "drop" in the cables.

Now referring to the accompanying diagram, A and B are the two cables; A′ B′ is a german silver wire of about one millimetre section, calibrated to insure a uniform resistance, and of about one-tenth the length of the two cables. This resistance can be strung up across the dynamo or testing room several times and its terminals connected to the two cable ends..



A Simple "Ground" Test.

G is a sensitive astatic galvanometer with one pole to earth and the other connected to a long, well insulated wire, the end of which can be slid along the german silver wire.

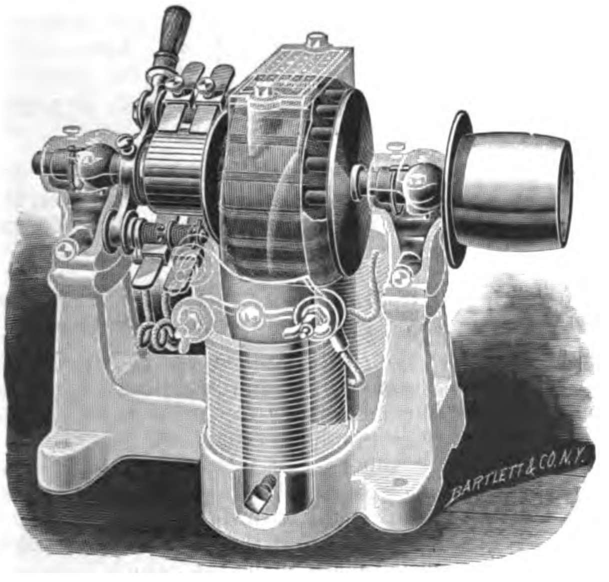
Now, upon passing a strong current through the cables and sliding the wire along, the galvanometer needle will come to rest just as it does in the Wheatstone bridge, for it is the same principle upon a large scale. This point on the wire will correspond exactly with the position of the fault in the cable, for $B'C' : D'C' = BC : DC$.

Great care must be taken to insulate well the other pole of the dynamo. The sensitiveness can be increased by increasing the current. Nearly every station has its bank of lamps which can be used for this purpose.

THE STANDARD CROCKER-WHEELER MOTORS.

SOME years ago we published an article by Mr. T. D. Lockwood upon "The Cheap John" in electrical engineering, calling attention to the lamentable fact that many of the failures in early electrical work had been due to the use of the cheapest and most inferior construction, instead of such as would be permanent and adequate to do its duty in an easy and enduring manner. The author longed for the day when the industry should have passed out of this stage, and all electrical work should be done as thoroughly as other engineering work, without regard to a somewhat greater first cost.

Indications are not wanting to show that, happily, in more than one department, the improved and durable construction so much to be desired in electrical apparatus, is now being carried out. Among the apparatus in which excellence of manufacture is a prime necessity for continuous and satisfactory work, the electric motor undoubtedly occupies a foremost position; and it was with this point prominently before them that the Crocker-Wheeler Electric Motor Co., of this city, some time ago undertook the designing of, and have now completed, a series of standard electric motors, a description of which will indicate the lines upon which the improvement has been effected.



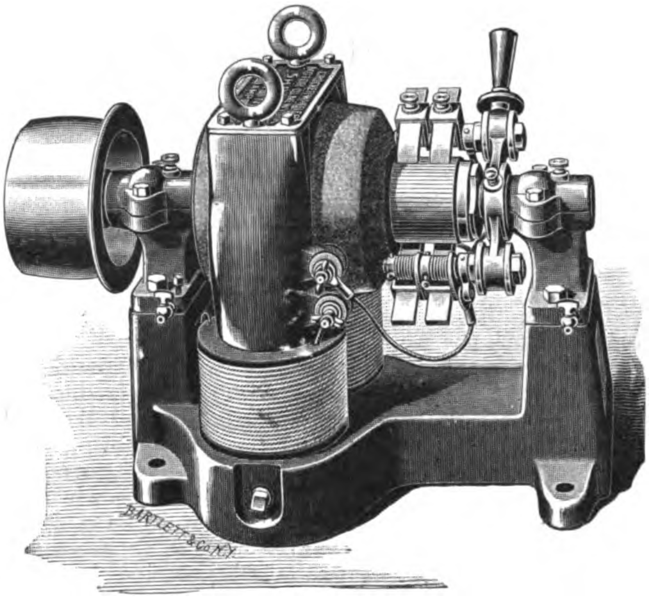
BARTLETT & CO. N.Y.

FIG. 1.—GENERAL TYPE OF CROCKER-WHEELER MOTOR, 1-6 to 1 H. P.

The general types of these motors is illustrated in the accompanying engravings, in which Fig. 1 represents the type employed in the sizes varying from $\frac{1}{6}$ to 1 horse power, and Fig. 2 the 5 horse power machine.

The field magnets are composed entirely of the best wrought iron, each magnet being forged in a single piece, and set deeply into the base, thereby securing great solidity and ample magnetic contact. The space for wire on the magnets is perfectly cylindrical in the form of an ordinary spool, thereby insuring smooth and perfect winding of the wire, and is short in length, permitting the shaft of the machine to be low enough to free it from vibration. By this construction the freedom of the base from magnetism is secured, and there is no tendency to leakage.

The armatures are sufficiently large in diameter to obtain slow speed, and are so designed that the wire winding is entirely embedded below the surface of the iron core, thus protecting it from all injury, holding it rigidly in position, and rendering it possible for the magnets to approach very closely to the core, so that an intense magnetic effect is produced. The armature is mounted upon a brass face-plate which is first turned perfectly true, and after completion the armature is very carefully balanced, so that when run at full speed the motion is hardly perceptible.



BARTLETT & CO. N.Y.

FIG. 2.—CROCKER-WHEELER 5 H. P. MOTOR

The bearings are all of the self-oiling type which do not require attention oftener than once in two to four weeks. The arrangement of these bearings is shown in Fig. 3. The base of the pillow block is hollow and contains a supply of oil which is carried over the shaft by two rings which travel upon the latter, and are caused to revolve by its motion. They dip in the oil and carry it continuously to the upper side of the shaft.

The bushings or brasses in which the shaft runs, rest, in turn, in universal, or ball, joints in seats of babbit metal in the pillow blocks, so that the bearings are sure to assume perfect allignment when the shaft is introduced. After the motor has run a month, the old oil containing the grit, etc., is drawn off by the pet cock at the base of the pillow block. This cock is then closed, and fresh oil is introduced by removing the thumb screw in the pillow block cap on top.

The brushes are held by a rocker arm which can revolve freely around the entire circle, without fear of the brass connecting parts "grounding" against the frame, a great advantage in special work where motors are to be adapted for use in unusual positions.

With the form of armature core employed, which reaches close to the field magnets, and the high grade of wrought iron used for the latter, the magnetism and therefore the power of these motors is maintained with a large reduction in the amount of wire employed. This great saving of wire not only reduces the weight of the machine, but materially increases its efficiency.

The speed of all the Crocker-Wheeler motors is very low. This, in many cases, makes countershafting, etc., unnecessary. Noiseless running is aided by the solidity of the base, which is of cast iron in one piece, forming also the yoke of the field magnets. This one casting is the heaviest part of the machine, and therefore brings the centre of gravity very low, securing steadiness and stability. The proximity of the armature core to the field magnets renders a high magnetic pressure unnecessary; therefore the magnetism escaping from the fields is very much reduced, so that no perceptible effect is produced at a short distance from the motor.

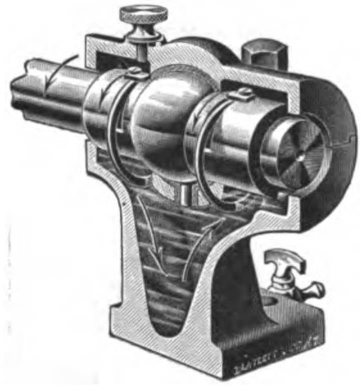


Fig. 3.—Detail of Self-Oiling Bearing.

The best double insulated wire is used throughout for the windings, the cores being first wrapped with oiled paper and heavy canvas saturated with shellac, and the motors are severely tested for insulation, none being passed with an insulation resistance of less than one megohm.

In every motor there are four ends to the wiring, two from the field and two from the armature. On all large motors built by the Crocker-Wheeler Co., these are led to four binding posts, the two field connections being made to the lower ones and the two armature connections being made to the upper ones, as shown in the diagram, Fig. 4.

In most cases one terminal of the armature and one of the field can be supplied by one outside or connecting wire, provided the other terminals are supplied by separate wires. Consequently the first connecting wire may be attached to the two posts marked 2 and 4. In the smaller size motors these binding posts are made as one, as shown in Fig. 5. Occasionally, however, the fourth binding post is put on, as indicated by the dotted line, when, for special purposes, such as when a reversing switch is used, it is necessary to have armature and field entirely separate.

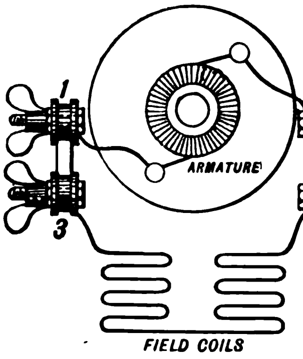

Fig. 4.—Terminals and Inside Connections of Large Motors.

In connection with the motors designed for incandescent circuits, there is provided a fire-proof and indestructible regulating box or rheostat for starting, stopping and varying the speed of the machine. This box is built entirely of slate, china and iron, neatly japanned. The arrangement of contacts in the switch on top of the regulator is such that both the field and armature of the motor are charged by the single operation of turning the knob, making it impossible to put the current on the armature before the field is charged, which has heretofore so often been the cause of the accidental burning out of motors.

The field is first charged through a small resistance coil, which is put in for the purpose of preventing a too sudden change in the magnetic strength of the latter, as well as to divide the spark when the motor is disconnected. The coils used for starting the armature are all of the same size of wire, carefully tried for carrying the full current of the machine at all speeds. With this fire-proof regulator the motor can therefore be slowed down and left running at any desired speed, indefinitely, and the usual caution, "Never to leave the box half turned on for fear of overheating and fire," is unnecessary.

The rocker arm is provided with a heavy insulated handle to enable all adjustments to be made without touching the conducting parts, and the entire machine is heavily japanned and baked at a high temperature, thus securing a polished surface which resists dirt and oil.

In addition to all these excellent features we may add finally a new departure, which consists in the fact that the name plate has stamped upon it not only the current, voltage and speed of the machine, but in addition thereto, the "constants" of the armature, the number of turns and size of wire, etc.

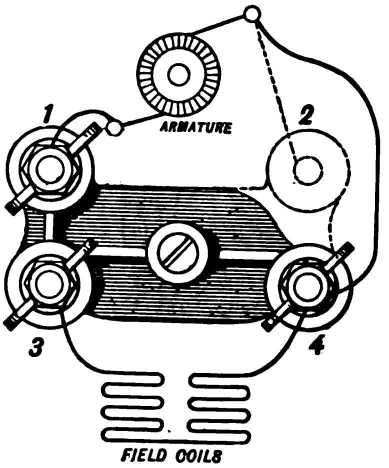

Fig. 5.—Terminal and Inside Connections of 1-4, 1-2 and 1 H. P. Motors.

PHOTOGRAPHIC REGISTRATION OF THE MOVEMENTS OF THE SEISMO-MICROPHONE.

According to the *Rivista Scientifico-Industriale*, Signor Baratta, finding some defects in the method of mechanical registration of the motions of the seismo-microphone, has substituted a photographic system with advantage. The device is briefly this :—The telephone wire is connected with a subterranean microphone. Before the telephone-diaphragm, and connected with its centre by a fine aluminum wire, is a short slip of the same metal, fixed below, and having a curved piece at the top, which rests against a small mirror, movable about a horizontal axis. This mirror reflects the light from a lamp and lens to photographic paper on a rotated drum. The light is momentarily shut off every quarter of an hour, by a shutter arrangement, worked electro-magnetically by the clockwork which moves the drum.

TELEPHONES IN FRANCE.

The number of subscribers to the nine chief telephone exchanges in France was given at the end of November as follows : Paris and suburbs, 9,200 ; Lyons, 800 ; Marseilles, 600 ; Bordeaux, 500 ; Lille, 450 ; Reims, 400 ; Roubaix, 350 ; Tourcoing, 500 ; Nancy, 176 ; Cannes, St. Etienne, Nantes, Troyes, Saint Quentin have about 150, and then some thirty towns, from 50 to 100 subscribers each. The total is only about 15,000 down to the 50 limit.

GUTMANN'S NEW ALTERNATING SMALL MOTOR.

Among those who have devoted their attention to the designing of alternating apparatus is Mr. Ludwig Gutmann, of Pittsburgh, Pa., who has recently invented a small motor, applicable especially for operating sewing machines, ventilating fans and light machinery.

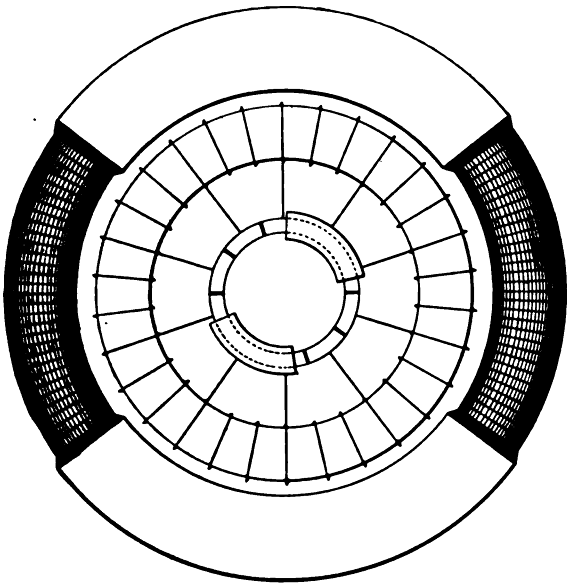

Fig. 1.—Gutmann's Alternate Current Motor.

The design of the motor is such that it starts automatically from a state of rest and operates at speeds independently of the number of current alternations, the field being energized by a single exciting current.

The accompanying engraving, Fig. 1, is a diagram of the construction, while Fig. 2 illustrates the practical form. It will be noted that the closed coil of the armature is many times subdivided, and the terminals of the subdivisions are connected to circularly arranged insulated plates. The supporting frame has four slots arranged in pairs whose members are diametrically situated, and short circuiting brushes are retained in one pair of slots by adjustable springs. When the motor is to be reversed, the brushes are changed to the remaining slots.

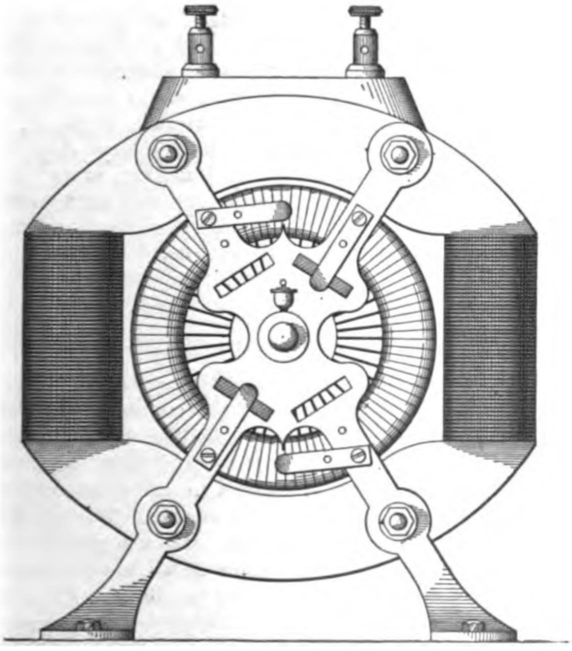

Fig. 2.—Gutmann's Alternate Current Motor.

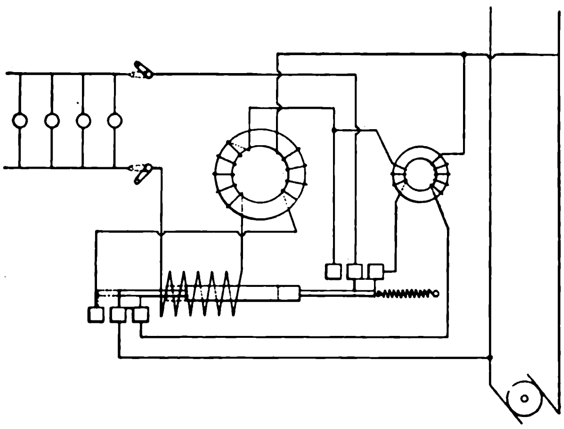
In the operation of the machine, the brushes permanently maintain a group of the coils closed upon themselves, while simultaneously including, and excluding, therefrom, one of the small subdivisions at each end of the group, the number of subdivisions being many times greater than indicated in Fig. 1. There is substantially no more sparking than in a direct current generator, because only one very small subdivision is opened from short circuit at any given instant. It is apparent from this that the armature poles are substantially stationary with respect to the field, while the armature rotates continuously.

An important detail of construction is that of the laminated field, the iron plates of which are stamped with a single die into two parts each, whose ends are interlocked and the plates bolted together. This construction enables the coils to be wound previously on formers in a lathe, and subsequently applied to the field, effecting thereby a quick and cheap means of manufacture. The construction is also applicable to direct current field magnet motors and dynamos.

GUTMANN'S SYSTEM OF ALTERNATE CURRENT DISTRIBUTION.

It is a well known fact that the efficiency of converters varies with the load, and that as the load decreases the efficiency diminishes. This, of course, entails a serious loss of energy, and it therefore becomes highly desirable to introduce a method by which converters may be operated continuously at their best efficiency. This is especially desirable in large installations including a number of converters, where the demand for current is apt to fluctuate between wide limits.



Gutmann's System of Alternate Current Distribution.

To effect this object, Mr. Ludwig Gutmann, of Pittsburgh, Pa., has devised the arrangement shown diagrammatically in the accompanying illustration. The method consists in keeping one converter permanently in circuit and automatically introducing more and more converters into circuit as more and more current is drawn from the secondary, and *vice versa;* and of cutting in, and out, the first converter according whether little or no current, respectively, is required.

This is accomplished by means of a single solenoid and core which operates a simple switch arrangement, by which the proper number of converters are included in the circuit, depending on the load.

Cleveland, O.—The East Cleveland Street Railroad Company, at its annual meeting, elected the following directors: A. Everett, G. E. Herrick, Charles A. Otis, John L. Woods, C. W. Wasson, M. A. Bradley, H. A. Everett. Officers were elected as follows: A. Everett, president; C. W. Wasson, vice-president; H. A. Everett, secretary and treasurer.

THE INSURANCE INSPECTOR ON HIS ROUNDS.

BY

Alfred B. Braddell.

Holding the position of electrical insurance inspector, I am naturally often asked to describe the kind of work found in my territory. In answering this question I have no hesitation in saying that cheap, which is only another name for bad, work predominates.

This is not wholly the fault of the contractor or constructing electrician, but partly of the general public, who ask that the work be put in in the best possible manner, and are then too reluctant to put their hands in their pockets and pay an adequate price. Nor can the public bear the whole blame, as they are in a great measure deplorably ignorant as to the nature of the electric current, and fancy that the installing of electric wires requires no more skill than the running of a wash line in one of their back yards.

It is certainly strange that the public, knowing, especially from the daily papers, what dangers may accrue from bad work, will persist in giving their contracts to so-called engineers (plumbers, gas fitters, etc.), instead of to men who have earned their names and reputation in the business, and can command their price.

Great trouble is found in small towns where the electric light company does no wiring but simply furnishes the current. This is the opportunity for the *electrical engineers* of that town. Naturally jealous of each other they cut their prices, even doing the work below cost in order to secure the job. As a result, the work is done in a careless manner, the conductors being undersized and out of proportion, secured with metal staples, and solder being an unknown quantity.

When making inspection of these places, the consumer, mistaking me for one of the company's employés, exclaims, in not a very pleasant tone of voice, interspersed with unmentionable adjectives, that he is obliged to light a match to find his lamps. Can this be wondered at? How can the evil be remedied? Such work is not only dangerous to property, but casts a blot on the electrical profession.

When speaking to an official of an electric light company about this kind of work I was told that the consumer put it in at his own risk. Is there not a good chance here of doing defective work by outsiders? Why should a company hand over, as it seems to me, their legitimate business, and assume no responsibility? I may ask here, if the insurance companies are to take the risk also and not ask any extra premium?

If they have no faith in their electrician, let them pay one in whom they can place reliance.

Let them guarantee safety to their customers, and place their confidence in their electrician, and so build up a reputation for themselves and the electrical business.

The following are a few incidents met with in my rounds:

Being asked to inspect a certain isolated plant, a man was detailed to conduct me through the premises. Not being able to trace out the different circuits, I asked him to draw them on a piece of paper. This he could not do but said he would call the electrician. After waiting a few minutes I heard a voice asking if I wanted to see him. Turning round I beheld one of the colored fraternity. I asked if this was the electrician and got an answer in the affirmative. My first question was, "What is the potential of your machine (one of the Edison type)? Answer: "500 volts." My next, "The E. M. F. of lamps?" Answer: "Oh that's where you've got me, Boss." I examined one of the lamps and as well as I remember it was marked 110 volts. I then explained that lamps of that E. M. F. could not be run from a machine having the potential as he stated. His answer was that he "guessed" I was right.

Arc lamps were placed in multiple series on this circuit, a very primitive resistance being in series with the same. The latter was made as follows: Three porcelain insulators placed in the form of a triangle on a piece of board, a coil of German silver wire (of apparently unknown resistance) resting on these, the ends being simply twisted around the copper conductors. The first of these inspected was broken in two, and another had become so greatly heated that the surrounding wood work of the building was considerably burned.

In another building an incandescent machine was being placed. The machine was set on a stone foundation, the bed plate being bolted directly to it without any insulating material whatever. On telling the man in charge that I did not consider it a very good method, and that I should prefer dry wood placed under the machine, he commenced an argument that stone was a better insulator than wood.

I was told a very good story of a man in charge of a plant I had occasion to visit, who directed one of his subordinates to give a machine a thorough cleaning. During this operation an ammeter which was in circuit was removed; when connecting up again this was reversed, thereby sending the needle in the opposite direction. When the man in charge observed this phenomenon he was greatly puzzled and could not understand why the "darned" instrument should be so erratic.

I will add but one more. On examining a joint in a building I found it wrapped with tin foil; on further examination I discovered that all the others were in the same condition. On meeting the individual who manufactured these, we held a somewhat lengthy and heated argument, on tinfoil versus solder, in which he claimed that the former afforded more carrying capacity for the current. I presume it is unnecessary to state the verdict.

The above are fair samples of some of the work as found, and the kind of men in charge. I do not wish it to be inferred that there is no good work being done; far from it, for where there is a reputable man in charge and no stint in price, work of a high character is the result. In many of the isolated plants there are practical mechanics having a good electrical knowledge in charge; but these are at a discount, the majority, as they have acknowledged to me, being "all right as long as the machines are."

As far as the central station for light or power is concerned, the day for placing delicate and expensive instruments and machinery under a "frame shanty" is disappearing, and good substantial brick or stone buildings are being erected. The construction, material, fittings, etc., for these is reaching a higher standard every day, and, calculating upon the present rate of building, it is only a question of a very short time when every city and town in the country will avail itself of one of the most powerful forces with which nature has endowed us.

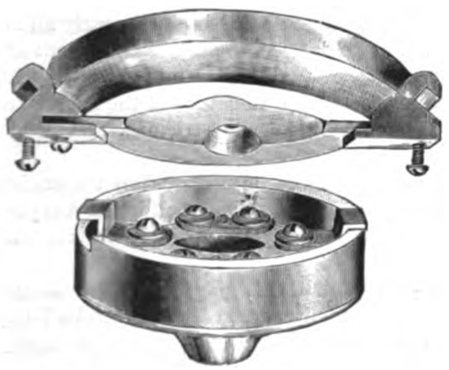
AN ELECTRIC RAILWAY LEAGUE.

It is proposed to form a mutual benefit society of the men employed on electric railroads throughout the country, with headquarters in Boston. Employés to be eligible for membership must be between the ages of twenty-one and fifty, must have some knowledge of electricity as applied to railroads, and must have worked on an electric road for six months. The admission fee will be $2, with quarterly dues of $1. When a member dies, each man will be assessed from 50 cents to $1 for funeral expenses, etc., and in case of illness, a member will be allowed $7 a week for a month, with further relief when necessary. The organizers propose to have the whole country divided into districts, with headquarters in each, all subject to the Boston lodge. If a member is out of employment, the order will seek to find a position for him, if worthy, and in case of necessity, will advance him money.

The order is not to be confused with, or regarded as, a labor organization, and no member will attempt to dictate to a company, or will take part in strikes.

A NEW ROSETTE CUT-OUT.

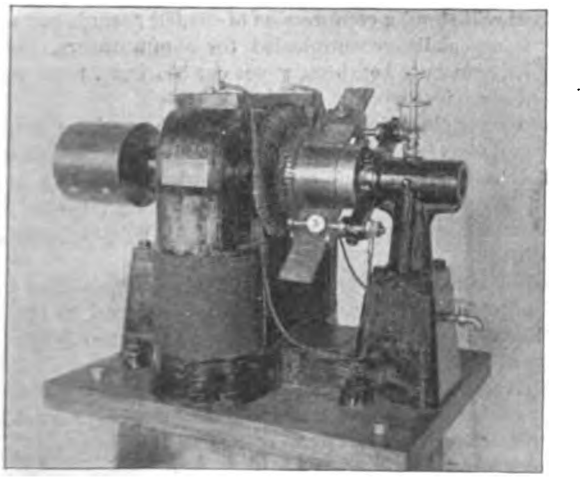
The accompanying illustration shows a new porcelain rosette cut-out, recently introduced by the Electric Engineering & Supply Co., of Syracuse, N. Y., which deserves much credit for its substantial design and neatness of finish. The porcelain base, which is also made in Syracuse, is particularly tough and will stand hard usage, obviating the trouble often experienced by line men, who in screwing up cut-outs crack the bases. The connections which screw to the line are milled smooth, so that the ears in the cap, to the opposite end of which the fuse is connected, fit into the slot milled in the side connection brasses. One of the ears enters at the side with one screw, as shown in the cut, and the other ear, by swinging the cover round, is pressed into the slot on the other side of the rosette, until it has reached its proper place, when it is stopped by the porcelain. With this design of cut-out very rapid work can be done, as it is only necessary to make the usual connections, after which the cap is put in place and half a turn of the screw driver permanently clamps it in position.



A New Rosette Cut-Out.

THE NEW KEYSTONE MOTOR.

The accompanying illustration shows a new type of motor built by the Keystone Electric Company, of Erie, Pa. This motor has a large steel shaft with long bearings running in self-aligning brass boxes, with oil cellars to receive the drip, which may be filtered and used a second time. It is well protected from external injury to winding, and its general make-up is one of strength, while avoiding undue massiveness. It runs noiselessly and without sparking under variations of load. The armature is of the Gramme ring type, of medium diameter, and supported on the shaft by means of a heavy brass spider. The coils are separated by insulation which makes a burn-out almost impossible.



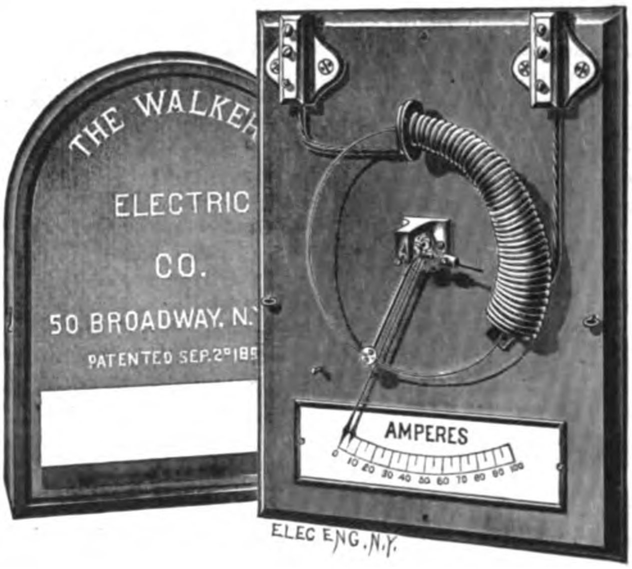
The Keystone Motor.

The 3 h. p. machine makes 850 revolutions per minute, and weighs about 400 pounds.

THE NEW WALKER AMMETER.

Some time ago we described and illustrated a very ingenious electric meter devised by Mr. George W. Walker, electrician of the Walker Electric Company, of this city. With this instrument, it will be remembered, a continuous record of the current strength is obtained by photography on a moving roll. At the end of the month the roll is removed from the motor and measured up. The accuracy obtained is almost absolute, and the record is one which is at all times open to inspection and verification.

More recently Mr. Walker has devoted his attention to the designing of a series of voltmeters and ammeters which shall embody both simplicity and accuracy. The ammeter in its present form is illustrated in the accompanying engraving. As will be seen, it consists of a solenoid having as a core a soft iron wire bent in the form of a circle. This wire is pivoted on jeweled centres and carries a pointer passing over a scale. The current passing through the solenoid draws in the core in proportion to the current strength, and the evenness of the divisions of the scale is obtained by the conical winding of the solenoid employed. The instrument shown is designed for a range of current from 0 to 100 amperes. Others are made for smaller and larger ranges, as desired. A series of voltmeters have also been designed by Mr. Walker on the same principle.



The Walker Ammeter.

ERECTION OF POLES IN NEW YORK.

Commissioner Gilroy proposes that it shall be made unlawful hereafter to erect any post or pole for carrying electric wires in front of the entrance of a dwelling-house in this city, or near a street corner upon a line with a crosswalk, or within a distance of ten feet of a street lamp. Poles or posts carrying electric wires are to be painted a light brown color a distance of ten feet above the sidewalk, the rest to be painted white. This will not apply to poles having a fire-alarm box, which are to be painted red. The owner's name, also, is to be branded on the pole in a conspicuous place, and no sign, poster or advertisement shall be placed upon such pole. An ordinance covering the points named, and prescribing penalties for its violation, was introduced in the Board of Alderman last week by Mr. Brown, at Mr. Gilroy's request, and referred to the Law Committee.

ENCOURAGING ELECTRICAL PROGRESS.

BY

Wm S Eaton

NOT very many months ago the superintendent of a large manufacturing concern was approached by a mechanic employed in the factory, and shown the drawings of an electrical attachment which could be adapted to a considerable extent to the machinery in use in one of the departments. He looked the drawings over and listened patiently to the verbal description of the proposed improvement, and encouragingly remarked, "Oh, pshaw! I don't take no stock in them electricity ideas." This man was as well posted on matters electrical, as he was on matters of grammar; and he condemned off-hand a device that he could not understand, and threw an obstacle in the way of what subsequently proved a very valuable improvement.

The originator of the idea alluded to, chanced to be a grade higher than a workman at the bench, and inasmuch as he was connected directly with the department using the machines, he, on the first opportunity, presented himself to the foreman having in charge these machines, and explained the idea to him. To use a common expression, this new man "caught on" at once. The apparatus necessary was of very simple character, and by taking the magnet from an unused electric-bell, and some few bits of iron and copper, bent and twisted, and filed "on the sly," they soon had the thing in working order. Two small Grenet cells furnished the current, and the thing worked like a charm. The proprietor of the factory was shown the device, and by his order one machine was fitted up properly with the electrical attachment, and the result surpassed all expectations. It is needless to say that an immediate order was given to fit *every* machine with the improvement, and to-day nearly twenty machines are fitted as described, in that factory, and doing a grade of work up to that time believed to be impossible, and at a saving of thousands of dollars annually.

As long as such silly prejudice exists against electrical progress, the electrical engineer will have a hard row to hoe. It is almost beyond belief, that, in order to benefit your employers, you must (in some cases) do it by stealth and like a criminal fearing discovery and exposure. The facts related above are strictly true, and come entirely within the writer's knowledge.

The field of invention is boundless, and the many new discoveries, instead of restricting the field, actually broaden it for wide-awake inventors. Nearly every new invention brought out suggests an application of its principles to some use not thought of by the inventor; generally speaking, the best field for the adaptation of such ideas is one that is least explored, that is, the field of manufacturing industries. Certainly, it is out of the question for electricians to know every purpose to which their inventions may be adapted. This much I do know: that the principles shown us in such machines as Mr. Berliner's gramophone, and Mr. Edison's phonograph are capable of being put to valuable uses in other directions than those intended by either of the inventors mentioned. *They* will probably devote their energies to perfecting their machines for the recording and reproducing of sound, and lose sight of other commercial uses to which the principle underlying their discoveries might be successfully applied. This is not to be wondered at, of course, and perhaps is best as it is.

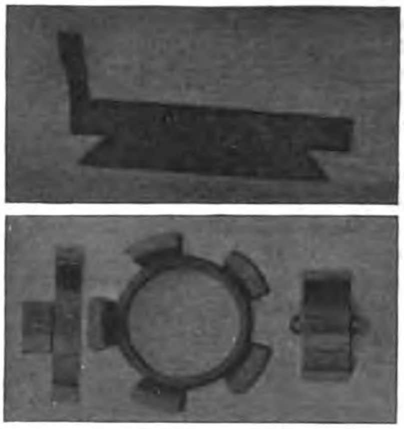
But this fact is emphasized, that men in authority in manufacturing concerns would do well to study thoroughly the progress made in electricity and the kindred sciences, and apply the knowledge thus acquired to uses in their own establishments. The result would be astounding; profits would increase, labor would be lightened, and the world be so much the happier. Yet I hardly look for any such good fortune. On the contrary, ignorance and prejudice, as described in the beginning of this article, will continue to flourish, and electricians will have to worry in the future, very much as in the past. Yet the time will come, Eli, when we will "get there with both feet."

EUREKA TEMPERED COPPER.

As is well known, copper is the basis of nearly all anti-friction metals, although in its native state it lacks sufficient strength for bearings and must be hardened by alloying it. This process, however, changes the whole structure of the copper from fibrous to granular, decreasing its tensile strength, and leaving it hard and brittle.

That copper was hardened or tempered by the ancients, no one can doubt, as edge tools and relics of all kinds composed of pure copper have been found, and are now on exhibition in countless collections.

The process by which this tempering was accomplished is claimed to have been re-discovered by the Eureka Tempered Copper Co., of North East, Pa., who are prepared to supply all kinds of copper cast solid, and tempered to any gauge that the work expected of it demands. This copper has a tensile strength of 64,480 pounds, and will stand a compression of 190,000 pounds per square inch. It is especially recommended for commutators, brushes, gear pinions, armature bearings, street car bearings, trolleys, and all kinds of electrical work.



FIGS. 1 AND 2.—DYNAMO PARTS MADE OF EUREKA TEMPERED COPPER.

The accompanying illustrations show some castings made by this company for various electrical concerns. They are all standard makes, and will be readily recognized. In Fig. 1 is seen the motor commutator of the C. & C. Electric Co., while Fig. 2 shows commutators of the Thomson-Houston, Westinghouse, and Brush patterns.

Tempered copper wire has nearly three times the tensile strength of ordinary copper wire, and is claimed to last three times as long. In the catalogue of the Eureka company are given the results of tests made at the Franklin Institute, the University of Pennsylvania, and the Union Iron Works of Pittsburgh, as well as a number of the most flattering testimonials from railroad and electric companies in all parts of the country.

PORTLAND, ME.—The Atlantic Telegraph Company has elected the following directors for the ensuing year: John W. Deering, of Portland; John J. Donovan, John F. Kimball, of Lowell; Henry P. Dewey, George P. Wescott, of Portland; Thomas G. Gerrish, Jr., Nathan D. Pratt, of Lowell. After adjournment the board met and organized by electing John W. Deering, president; John J. Donovan, treasurer, and Nathan D. Pratt, clerk.

A PRACTICAL GUIDE TO THE TESTING OF INSULATED WIRES AND CABLES.—XIV.

(*Copyright The Electrical Engineer.*)

BY

Herbert Laws Webb

In averaging the capacities of a number of wires of the same length (such as the different conductors of a telephone cable) when the deflections vary, it is not necessary to work out each deflection separately and average the results, as was shown to be the case in averaging the insulation resistance of a number of wires. The average capacity can be worked out from the average discharge deflection. The reason for this is simple and obvious. With the insulation test the constant is divided by the deflections, and if these vary much, the average of the results of each deflection worked out separately will not agree with the result obtained by working out the average of the deflections; it is advisable therefore to take the average of the insulation resistances of the various wires in order to state the average insulation resistance of the cable. In the capacity test, however, we divide the deflections by the condenser discharge, and the divisor therefore remains unvariable. It is obvious that the average will be the same, whether it is determined by averaging the capacities of the separate wires, or averaging the deflections and working out the mean deflection.

A simple example will serve to make this clear. Having from a condenser of .1 microfarad capacity obtained a discharge of 200 divisions, we take discharges on six wires in a cable which give deflections of 240, 250, 250, 260, 240 and 260, respectively. Dividing by 2,000 we find their respective capacities to be .12, .125, .125, .13, .12 and .13 microfarad. The average capacity of the six will be .125 microfarad. Now summing the deflections we get 1,500, which, divided by 6, the number of wires, gives a mean deflection of 250. Dividing this by the condenser discharge 2,000 we obtain the same result, .125 microfarad, as the average capacity of the six wires.

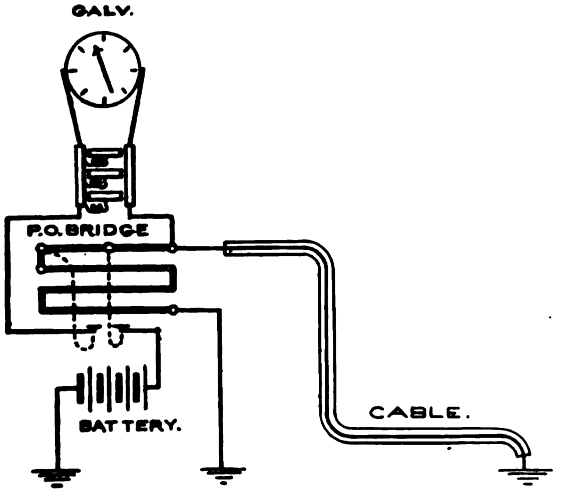


Fig. 34.—Connections for Resistance by Post Office Bridge.

In testing a telephone cable it is usual to test about twenty conductors for capacity; as the deflections will probably vary throughout by a few divisions, it is more convenient to obtain the average by working out the mean deflection, than by summing the capacities of the wires. When testing a telephone cable for capacity, all the wires, except the one being tested, must be grounded. A test made with the cable not grounded would show a lower capacity, owing to the much greater thickness of insulation surrounding most of the wires. This would not be the capacity of the cable under working conditions and the test would be worthless as an indication of the quality of the cable. In this type of cable it is sometimes desirable to test the capacity of a pair of wires, the ends being connected together at the further terminal of the cable, and the end of the second wire joined to one pole of the battery and the galvanometer, the earth connections being removed. The capacity of the loop will be one-half the capacity of one of the conductors, or one-quarter the capacity of the entire length of wire contained in the loop.

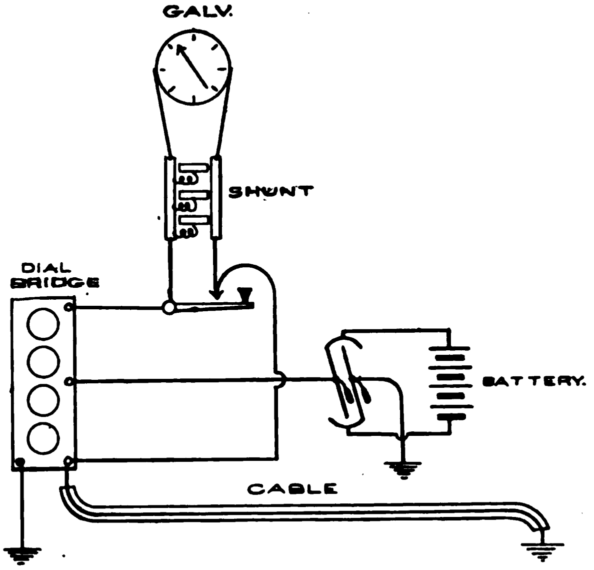

Fig. 35.—Connections for Resistance by Dial Bridge.

In making factory tests for capacity, when a long length of cable wound on a drum is to be tested, the sheathing of the cable should be grounded, the ground connection being made with great care, in order to avoid inductive action between the different turns. In testing single wire cables for capacity, when coiled up, it is best to connect both ends to the instruments in the manner described above, no earth connection being employed. In this way any possible error, by reason of induction from one turn to another, will be eliminated. As already explained, a wire connected in this way will only receive one-quarter the charge that it will take with one end free; therefore the apparent capacity must be multiplied by four to obtain the real capacity of the wire.

TEST FOR CONDUCTOR RESISTANCE.

The principle of the Wheatstone bridge for measuring the resistance of conductors has already been explained, but may be appropriately recapitulated here. It consists, briefly, in offering two paths for the battery current, one along the conductor to be measured, and the other by the variable resistance; by connecting two points in these separate paths through a galvanometer or other instrument (such as a telephone) capable of indicating the existence of a difference of potential between the two points, the variable resistance can be intelligently manipulated until equal potential at the two points is reached; the resistances of the two paths open to the current are then equal, and the resistance of the conductor can be read by the value of the variable resistance in circuit. In referring to the schematic diagram given in the introductory chapter, the analogy employed was that of an ordinary balance, the arms of the bridge being the beam, the adjustable resistance the weights, and the galvanometer the pointer. This was assuming the arms of the bridge to be of equal value, as the two halves of the beam always are. But the bridge has a far wider range of measurement than this, which would limit our measurements to the total value of the resistance coils. Pursuing the analogy of the balance, the arms of the bridge, being adjustable, constitute a sort of reversible steel-yard, and by altering their ratio we can make our weights a thousand times heavier than they are by themselves, or a thousand times lighter, enabling us to weigh accurately with the same set of weights, either very heavy or very light bodies, or in other words, to measure very high or very low resistances. This property alone is sufficient to stamp the Wheatstone bridge as the most beautiful measuring instrument known to science.

As already described, the arms of the bridge each contain three coils having resistances of 10, 100, and 1,000 ohms respectively; some bridges have two additional coils of 10,000 ohms each, and bridges are occasionally made with five coils in each arm, the lowest of one ohm, and the highest of 10,000 ohms resistance.

If we desire to measure a resistance with an accuracy of one ohm only, the ratio of the arms must be equal, that is, two coils of equal value must be unplugged. In any case, two of the proportional coils must be unplugged when making measurements with the bridge, or the galvanometer will be short-circuited and no readings obtained.

If a small resistance is to be measured and the result is required to fractions of an ohm, the resistance in the arm nearest the coils must be made larger than the resistance in the arm to which the unknown resistance is connected. Thus, if we unplug 100 in the B arm (the left in the Post-office bridge and the right in the dial pattern) and 10 in the A, the current strength in the variable resistance will be one tenth of that in the unknown, and the value unplugged in the variable resistance will be ten times greater than the unknown resistance. When balance is obtained, the resistance unplugged, divided by ten, will give the resistance of the conductor being measured.

It is plain, therefore, that, as we can make the ratio either way, 10 to 100, 10 to 1,000 or (with the dial bridge) 10 to 10,000, we can give to each ohm in the variable resistance a value of $\frac{1}{10}$, $\frac{1}{100}$ or $\frac{1}{1000}$ of an ohm, or a value of 10, 100 or 1,000 ohms, according to whether we are measuring low or high resistances.

A simple rule to remember, calling the arm nearest the coils *b*, and the arm to which the conductor to be measured is attached *a*, is: When measuring low resistances make *b* higher than *a*, and when measuring high resistances make *a* higher than *b*. In the Post-office bridge *b* is on the left when the keys are nearest to the manipulator; in the dial bridge the ratio coils are placed in front of the dials and *b* is to the right. Fig. 34 shows the connections for measuring conductor resistance with the Post-office bridge, and Fig. 35 with the dial bridge. In these diagrams it is assumed that only one end of the conductor is available for connection to the instruments, the other being put to earth. In this case the end of the variable resistance, *i. e.*, the bridge coils, and one pole of the battery are also put to earth. The general similarity between these diagrams and that shown in Fig. 7, is easily apparent.

If both ends of the conductor to be measured are available, the second end is connected to the terminal of the coils, the second pole of the battery also being joined to the same point. As these three connections were all to earth in the previous case, it is obvious that joining them together in no way alters the flow of current in the system. When measuring the resistance of a loop in this manner with both ends connected to the bridge, it is best to disconnect the earth wire entirely, as otherwise some difficulty will probably be found in obtaining a balance. For this reason, if the terminal plate for earth connections is used, it is best to have it made so that the earth terminal may be cut off from the rest by means of a plug, as previously suggested.

It will be noticed that the adjustable coils are joined to the ratio coils by two brass blocks between which a plug is inserted. This plug, which is termed the "infinity" plug, should always be in place when the bridge is being used for measuring resistances, otherwise the coils are *disconnected* and the resistance is of course infinite. If it is desirable to use the coils merely as a resistance, such as for making a shunt, the removal of the infinity plug serves to disconnect them from the ratio coils.

In the dial bridge there is a pair of blocks with a connecting plug at the end of each set of ratio coils. The plug to the right is the infinity plug and should be in place; that to the left should be removed when measurements are being made, or the conductor being tested will be short-circuited and balance made impossible. As a matter of fact, the coils being between the two terminals at the extreme ends of the brass blocks, either plug could be used as the infinity plug, provided that the unknown resistance were connected at the opposite end of the instrument, but it will be found more convenient in practice to keep to one method of connecting up.

TWO NEW HILL SWITCHES.

A good switch is one of the most important features in an electric light installation, and we therefore illustrate two novel switches just designed by Mr. W. S. Hill, of 133 Oliver street, Boston, which form an important addition to his already very complete line. Fig. 1 shows a double pole transfer switch, having two sets of terminal contacts, either set of which may be put in connection with the dynamo at will, thereby transferring the current from one dynamo to either one of two separate circuits, or to connect either one of two dynamos with one circuit. Fig. 2 shows a new dynamo switch designed to be used at the dynamo, or on the switchboard between the dynamo and the main line. It consists of one of Mr. Hill's ordinary switches and a main line fuse block combined, mounted on one base of slate, and is a very compact and substantial piece of apparatus.

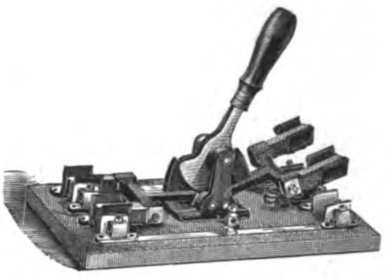

FIG. 1.—NEW HILL SWITCHES.

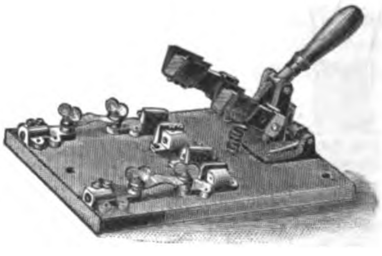

FIG. 2.—NEW HILL SWITCHES.

WORCESTER, MASS.—The Electric Light Company, at the annual meeting, elected the following directors: Thomas M. Rogers, Stephen Salisbury, A. B. R. Sprague, Theo. C. Bates, S. E. Hildreth, Josiah Pickett, Samuel Winslow, Loring Coes, N. S. Liscomb, W. A. Denholm, Alzirus Brown; treasurer, Herbert H. Fairbanks; superintendent, W. H. Coughlin. The directors re-elected T. M. Rogers president.

THE ELIESON ELECTRIC METER.

Among the numerous principles which may be applied to measure the volume of current passing through an electric circuit is that depending upon the electrolysis of a liquid, such as water. The gas generated can be readily collected and its volume measured, which thus affords a simple means of metering the current.

In applying this principle Mr. C. P. Elieson, of London, at present in this city, has devised the several forms of apparatus. It is evident that to acertain the quantity of current which has passed through a circuit we may meter either the volume of gas generated or register the pulsations caused by the accumulation of the gas as it is generated.

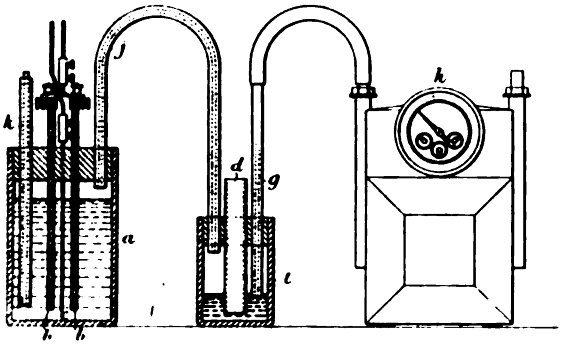

Fig. 1.—The Elieson Electric Meter.

Mr. Elieson has carried out the first method in the apparatus illustrated in the engraving, Fig. 1. Here a closed vessel *a* containing acidulated water is provided with electrodes of carbon for the negative, and platinum for the positive, which are connected with the main conductors. The tubes *d* and *g* are inserted in the vessel *i*, containing mercury, and which is connected with the vessel *a* by means of a tube *j*. *k* is a tube through which the vessel *a* is supplied with liquid, the tube being closed at the upper end.

By this arrangement it will be readily understood that the gas generated by the electrolysis or decomposition of the liquid in the vessel *a* will pass through the tube *j* into the vessel *i*, causing the mercury to rise in the tubes *d* and *g*, and as soon as the lower end of the tube *g* is exposed the gas will escape through the tube *g* into the meter. By this means the gases are kept under a constant and equable pressure without the necessity of maintaining constant the level of the liquid in the vessel *a*.

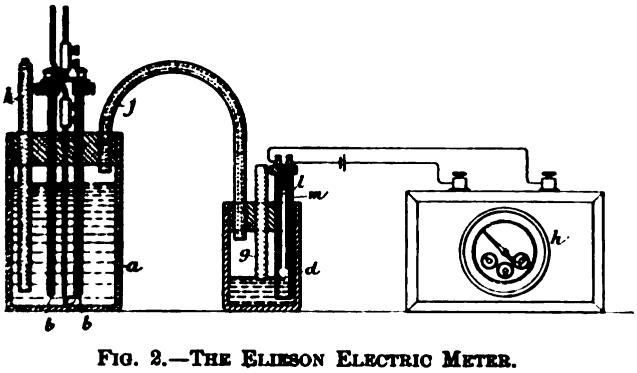

Fig. 2.—The Elieson Electric Meter.

In the second type of meter above referred to, depending upon the registration of the pulsations caused by the accumulation of gas, Mr. Elieson employs the construction shown in Fig. 2. This meter is practically identical with that illustrated in Fig. 1, except that instead of the gases generated escaping through the tube *g* into a meter they are now allowed to escape freely through that tube; but as the mercury rises in the tube *d* it completes an electric circuit by means of two wires *l m* in the tube *d*, so as to short-circuit an electro magnet which actuates a counter *h*. Directly the gases escape, the mercury falls, as before, thereby breaking the circuit, and so on, continuously, so that each pulsation caused by the accumulation of the the gases generated is registered.

For measuring alternating currents it will be obvious that one or both of the electrodes must be made relatively small and of suitable material, such as platinum. Where a current of electricity of a certain quantity is to be measured—that is to say, a current not below a minimum required for, say, supplying a few lamps—then the gas generated need not be compressed, but can pass direct to the meter.

A CHART OF WOODEN CLEATS.

The advent of electricity as one of the prominent modern industries created a demand for cleats for the supporting of wires, and this demand has steadily increased from the very inception of the art. When conductors carrying heavy currents became a necessity, certain regulations had to be made for the safe running of wires, and the underwriters' rules in this regard are well defined and pretty well understood.

Heretofore the manufacture of cleats has, to a great extent, been confined to furniture manufacturing and other similar establishments, where the small stock which would otherwise become waste was used for this purpose, this branch of the business being treated as a side-issue. But as the demand for cleats, as well as all other kinds of material needed in electrical construction work steadily increases, manufacturing establishments are springing up in every direction to supply this demand. The quantity of cleats needed at the present time is enormous. They are made of different materials, such as porcelain and various compounds; but these modifications and refinements have not as yet come into such general use as to interfere seriously with the old-fashioned wooden cleat, as wood costs less and answers all the essential requirements, cleats never being used in proper construction except where everything is dry and the wires are not liable to be disturbed.

The various sizes and designs of cleats in general use are illustrated in the accompanying chart. Those used for electric lighting purposes, it will be noticed, have a distance of 2½ inches between the wires, except numbers 400 and 401, where the distance is increased. This latter style of cleat is used where the wires are run along brick and fire-proof walls before the plaster is put on. Its office is simply to hold the wires in position until the plaster is hard, and it is called the "plaster cleat." The others shown are those which are used for open and surface work and when well and symmetrically made present a neat appearance.

The Independent Bung Co., of this city, to whose courtesy we are indebted for the use of the chart, arranged by Mr. M. C. Sullivan, manufacture all kinds of cleats, the special machinery for the purpose of producing the cleats having been designed by Mr. H. B. Wheatcroft, of that company.

Owing to the fact that the different makes of insulated wires have such varied diameters, caused by the difference in the thickness of insulation, it is a difficult matter to determine absolutely the size of the grooves that will apply in all cases; but a difference of one-eighth inch in size will be found to cover a very wide range.

The value of a chart such as here presented can be appreciated when it is considered that past experience has developed the most vexatious delays and annoyances in ordering cleats, owing to the absence of any catalogue from which to select the exact size. This is particularly true in cases where practical men have been compelled to work at distances from the home office, and having occasion to order supplies, had nothing to express their wants except a description, which has in a great many cases failed entirely, occasioning delays and expense. By the use of this sheet, the ordering of cleats in the future will be a very easy and satisfactory matter.

The hum of the electric motor is a song of emancipation.
—*Frank J. Sprague.*

RETROSPECT AND PROSPECT.

ONE of the most interesting features of the meeting of the National Electric Light Association at Providence this week is the celebration of the first decade of commercial, practical electric lighting in this country. If the retrospect be taken in the right spirit, there is always advantage in surveying, at the end, its toils and dangers over, the road we have traveled ; and in casting the backward glance upon the vicissitudes and advances of electric lighting, much good will be derived if only in the way of stimulus. An English statesman who had been engaged in a great reform movement, once suggested to his hearers that as they had reached the hilltop, they might as well "rest and be thankful." The sentiment is not without merit, but is evidently suited to people of a more lymphatic temperament than Americans. If there is one thing we do, it is to press towards the mark of perfection that has not yet been attained in any art and which during the past ten years in electric lighting has barely become visible.

Ten years ago there was electric lighting, but no electric light art. To-day, by stages of evolution and across the debris of "systems" that have had their day and ceased to be, we have arrived at definite and fairly satisfactory ideas in construction and practice. Principles have been determined and methods have been standardized. Moreover, there is a clearer understanding of the things to be aimed at. The central station is no longer regarded as a kind of feudal stronghold for either arc light or incandescent lighting or for some single, special variety of them. Time was, and not very remote, when the tribal warfare frightened and bewildered the public, until at last peace was often vouchsafed only through the exhaustion of the combatants and their extinction in each other's embrace. Even now the progress of the industry is retarded by such bellicose displays, but on the whole it may be said that the art has cleared itself pretty thoroughly of the contests and litigations that have preyed on its profits and prejudiced its prosperity. A central station has become a place from which a customer expects any kind of light or power service that he has a mind to call for ; and if told that he cannot get this or that, the customer is as much surprised as though his newsdealer would only sell him papers of one political stripe, or his tobacconist refused to carry a popular brand of cigars. One of the main things learned in these ten years is that a station exists to manufacture current on as large a scale and as economical a plan as possible, and that the station is most successful that leaves its patrons the freest to decide on the size of the units of light and power that they want. Another great point learned is that this current should be metered. A third lesson is that cheap work is the dearest in the long run. This last point may not seem very striking but there were not a few men who thought that electricity was to be the exception proving the validity of the rule.

This idea that a central station is a current factory is beginning to permeate. Arc lighting has been supplemented and even surpassed by incandescent lighting. There has arisen the demand for motors, and now heaters and welders ask for a place on the circuits. The successful inventions of the immediate future are those which shall harmonize and satisfy these needs from the one plant.

As for the Association, it is true that it has not yet completed a decade of existence, but it may wisely avail itself of this period of review and retrospect to invite attention to its excellent work since 1885, and to ask for new and enlarged support. The Association is a representative body solely on account of its creditable record and its widespread influence, and not at all on account of the largeness of its membership. But it ought not to stay at its present low total of members. Already there are 1,500 central station plants at least, and new ones are organized every week. The proportion of active membership from these local companies ought to be ten times as large as it is now, and the best way to celebrate the first decade will be to take steps for an active canvass and propaganda that will place the Association in the very front rank among bodies formed to promote and protect the interests of great industries.

MODERN ELECTRICAL ENGINEERING.

THE promising character of electrical enterprises early in the art induced many to enter this field, who by training were very ill-prepared to carry out work in the manner which the experience of late years has demonstrated to be necessary. As a result, not only bad electrical, but bad mechanical, designs in electrical apparatus were not infrequent, and hence probably has come the dictum, sent forth it is true by high authority, that the electrical engineer ought to be nine-tenths mechanical and one-tenth electrical. As Prof. Crocker points out in another column, however, the times have changed rapidly, and to-day the relative proportion of electrical and mechanical make-up required in the competent electrical engineer may be fairly said to be nearly the reverse of that designated above. In other words, as he forcibly remarks, the electrical engineer ought to be an engineer in the broadest and best sense of the word. Who but one thoroughly versed in electrical principles and their application can be depended upon to bring about the great improvements which are looked forward to, involving simplicity in the armature, commutator and brushes, means for avoiding sparking, etc.? It is on these lines largely that Prof. Crocker has laid out his course of instruction at Columbia College, as described in this issue, and while not ignoring the proper importance of mechanical engineering as an aid to the work, we believe that he has taken a right view of the case and subordinated the mechanical to the electrical part of the course at Columbia.

MR. SPRAGUE ON THE RAPID TRANSIT PROBLEMS OF NEW YORK.

As we have already noted, the *Commercial Advertiser* has been devoting a generous portion of its space to the opinions and ideas of electricians and electrical engineers on the solution of the rapid transit problems of New York. That space has been well bestowed, for electricity will have more and more to do with passenger and freight transportation as the years roll by, and these are the times when the work is taking shape. We are now glad to note that the *Commercial* has left to Mr. Frank J. Sprague the summing up of the main points of the situation and of the argument, and in its issue of Monday last has devoted a whole page to his treatment of the question, in the form of a very able and cleverly-done interview by Mr. George Heli Guy. For some years past, Mr. Sprague has been studying the New York rapid transit problem, and has saturated himself with its facts and statistics. He now stakes his reputation, which is no mean one, on the ability of the electrical engineer and inventor to deal satisfactorily with the difficulties of the case and to give New York an adequate system of underground electric transit. We shall have occasion to return to this matter, and in the meantime would advise our readers to secure a copy of the *Commercial* and study Mr. Sprague's masterly and exhaustive presentment of the case.

ELECTRIC "RAPID TRANSIT" FOR CHICAGO.

While New York has just fairly begun the earnest agitation of a better means of transit than is now available and has practically settled upon a plan involving some method of underground operation, Chicago has just begun a like agitation, in which, however, it has thus far confined itself to an elevated railway. In this respect it has the great advantage of the experience gained on the roads running in this city. If the plan to be adopted in Chicago offered no other improvement than the mere substitution of electricity for steam locomotives on the elevated road, that alone would be a powerful argument in favor of the adoption of the system. But the added advantages which the electric system will afford, such as the operation of single cars at high speeds, are such as will, we think, place it beyond the competition of any other method of propulsion. The plan proposed by Mr. Adams possesses several novel features and the electrical methods proposed, though not worked out to the last detail, present no difficulties with which the electrical engineer of to-day ought not to be able to cope successfully.

THE "CHEAP JOHN" IN ELECTRICAL WORK.

Probably no one has a better opportunity of knowing the character of the work as it exists to-day in electrical installations of every description than the insurance inspector, whose duty it is to examine carefully into the arrangements adopted, and to establish the premium rate accordingly. Hence the contribution to our columns from Mr. A. E. Braddell, the electrical inspector for the Middle Insurance Department, is of more than passing interest. It is, indeed, to be regretted that, as Mr. Braddell points out, cheap, *i. e.*, bad work still predominates. The reason for this it is not difficult to divine, when we consider the prevailing desire of most of us to obtain the greatest return from the least possible outlay. Not being able to distinguish between good and bad work, a private consumer is apt to put his work in the hands of men unfitted for it but whose prices may be somewhat lower than those of others competent to do it properly and honestly. Mr. Braddell, in analyzing the cause for this state of affairs, points out what has probably more than anything else contributed to bring about this deplorable state of affairs. This consists in the fact that in many cities, especially in small towns, the electric light companies do not themselves undertake or supervise the wiring of the premises of consumers, but simply furnish the current. The competition which is thus at once brought about between private concerns, added to frequent incompetency, is largely responsible, no doubt, for the present state of affairs. The central station, for its own credit, ought, if not directly engaged in the work of wiring, at least to supervise the wiring upon which its current is used, and the consumer ought not to be allowed to assume any risk. This would still leave the work open to competition, but under the restriction of competent superintendence by, what ought to be, a disinterested party. On the other hand, as has already been suggested, a system of examinations and licenses granted to those engaged in electrical installation work, such as that carried on by the New England Electric Exchange, would go far towards improving matters, for even if it did not improve the quality of the material employed, it would undoubtedly add to security by having the poorer material at least properly installed. We think the subject one which the National Electric Light Convention might very profitably take up and discuss at the Providence meeting.

100 Pages and Supplement.

The issue of The Electrical Engineer this week, barely ten months after its change from monthly to weekly publication, is one of 100 pages. There is also a Colored Supplement of wooden cleats for electrical purposes.

ELECTRICITY IN TRANSITU: FROM PLENUM TO VACUUM.

BY WM. CROOKES, F. R. S.

(*Concluded.*)

The next stage, dealing with more rarefied matter, is that of phosphorescence. Here is an egg-shaped bulb, shown in Fig. 19, containing some pure yttria, and a few rough rubies. The positive electrode, B, is on the bottom of the tube under the phosphorescent material; the negative, A, is on the upper part of the tube. See how well the rubies and yttria phosphoresce under molecular bombardment, at an internal pressure of 0.00068 mm., or 0.9 M.

A shadow of an object inside a bulb can also be projected on to the opposite wall of the bulb by means of an outside pole. A mica cross is supported in the middle of the bulb (Fig. 20), and on connecting a small silvered patch, A, on one side of the bulb with the negative pole of the induction coil, and putting the positive pole to another patch of silver, B, at the top, the opposite side of the bulb glows with a phosphorescent light, on which the black shadow of the cross seems sharply cut out. Here the internal pressure is 0.00068 mm., or 0.9 M.

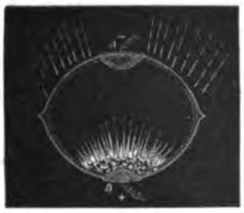

FIG. 19.—P = 0.00068 mm. = 0.9 M.

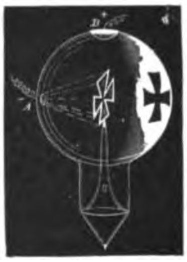

FIG. 20.—P = 0.00068 mm. = 0.9 M.

Passing to the next phenomenon, I proceed to show the production of mechanical energy in a tube without internal poles. It is shown in Fig. 21 (P = 0.001 mm., or 1.3 M.). It contains a light wheel of aluminum, carrying vanes of transparent mica, the poles, A, B, being in such a position outside that the molecular focus falls upon the vanes of one side only. The bulb is placed in the lantern, and the image is projected on the screen; if I now pass the current you see the wheel rotates rapidly, reversing in direction as I reverse the current.

Here is an apparatus, Fig. 22, which shows that the residual gaseous molecules when brought to a focus produce heat. It consists of a glass tube with a bulb blown at one end and a small bundle of carbon wool, C, fixed in the centre, and exhausted to a pressure of 0.000076 mm., or 0.1 M. The negative electrode, A, is formed by coating part of the outside of the bulb with silver, and it is in such a position that the focus of rays falls upon the carbon wool. The positive electrode, B, is an outer coating at the other end of the tube. I pass the current, and those who are close may see the bright sparks of carbon raised to incandescence by the impact of the molecular stream.

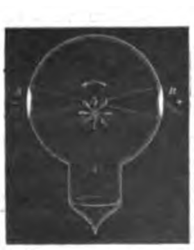

FIG 21.—P = 0.001 mm. = 1.3 M.

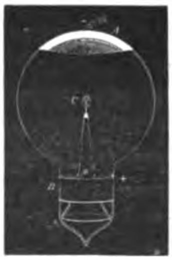

FIG. 22.—P = 0.000076 mm. = 0.1 M.

You thus have seen that all the old "radiant matter" effects can be produced in tubes containing no metallic electrodes to volatilise. It may be suggested that the sides of the tube in contact with the outside poles become electrodes in this case, and that particles of the glass itself may be torn off and projected across, and so produce the effects. This is a strong argument which fortunately can be tested by experiment. In the case of this tube, Fig. 23, P = 0.00068 mm., or 0.9 M., the bulb is made of lead glass phosphorescing blue under molecular bombardment. Inside the bulb, completely covering the part that would form the negative pole, A, I have painted a substantial coat of yttria, so as to interpose a layer of this earth between the glass and the inside of the tube. The negative and positive poles are silver discs on the outside of the bulb, A being the negative, and B the positive pole. If, therefore, particles are torn off and projected across the tube to cause phosphorescence, these particles will not be particles of glass, but of yttria, and the spot of phosphorescent light, C, on the opposite side of the bulb will not be the dull blue of lead glass, but the golden yellow of yttria. You see there is no such indication; the glass phosphoresces with its usual blue glow, and there is no evidence that a single particle of yttria is striking it.

PHOSPHORESCENCE IN HIGH VACUA.

Very many bodies, such as ruby, diamond, emerald, alumina, yttria, samaria, and a large class of earthy oxides and sulphides, phosphoresce in vacuum tubes when placed in the path of the stream of electrified molecules proceeding from the negative pole. The composition of the gaseous residue present does not affect phosphorescence; thus, the earth yttria phosphoresces well in the residual vacua of atmospheric air, of oxygen, nitrogen, carbonic anhydride, hydrogen, iodine, sulphur, and mercury.

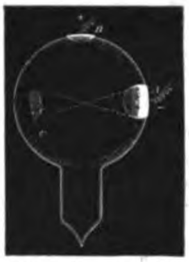

FIG. 23.—P = 0.00068 mm. = 0.9 M.

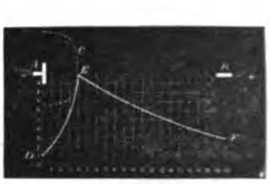

FIG. 24.—P = 0.25 mm. = 330.0 M.

With yttria in a vacuum tube, the point of maximum phosphorescence, as I have already pointed out, lies on the margin of the dark space. The diagram, Fig. 24, shows approximately the degree of phosphorescence in different parts of a tube at an internal pressure of 0.25 mm., or 330 M. On the top you see the positive and negative poles, A and B, the latter having the outline of the dark space shown by a dotted line, C. The curve, D. E. F., shows the relative intensities of the phosphorescence at different distances from the negative pole, and the position inside the dark space at which phosphorescence does not occur. The height of the curve represents the degree of phosphorescence. The most decisive effects of phosphorescence are reached by making the tube so large that the walls are outside the dark space, whilst the material submitted to experiment is placed just at the edge of the dark space.

Hitherto I have spoken only of phosphorescence of substances placed under the negative pole. But from numerous experiments I find that bodies will phosphoresce in actual contact with the negative pole.

This is only a temporary phenomenon, and ceases entirely when the exhaustion is pushed to a very high point. The experiment is one scarcely possible to exhibit to an audience, so I must content myself with describing it. A U-tube, shown in Fig. 25, has a flat aluminum pole, in the form of a disc, at each end, both coated with a paint of phosphorescent yttria. As the rarefaction approaches about 0.5 mm. the surface of the negative pole, A, becomes faintly phosphorescent. On continuing the exhaustion this luminosity rapidly diminishes, not only in intensity, but in extent, contracting more and more from the edge of the disc, until ultimately it is visible only as a bright spot in the centre.

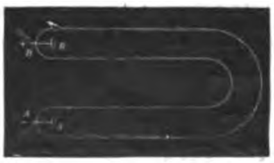

FIG. 25.

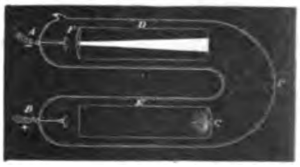

FIG. 26.—P = 0.000076 mm. = 0.1 M.

If the exhaustion is further pushed, then at the point where the surface of the negative pole ceases to be luminous, the material on the positive pole, B, commences to phosphoresce, increasing in intensity until the tube refuses to conduct, its greatest brilliancy being just short of this degree of exhaustion. The probable explanation is that the vagrant molecules I introduce in the next experiment, happening to come within the sphere of influence of the positive pole, rush violently to it and excite phosphorescence in the yttria, whilst losing their negative charge.

LOOSE AND ERRATIC MOLECULES.

I will now show you a piece of apparatus that clearly illustrates the cause of phosphorescence at the positive pole. A drawing of this tube is shown at Fig. 26. A C B is a U-shaped tube with terminals, A and B, at each end; D and E are two mica screens covered with a phosphorescent powder, having at F and G other screens with a small slit in front, so as to allow only a narrow beam of charged molecules to pass through. At first the tube is exhausted to a pressure of 0.076 mm. or 100 M., and you see how sharp and slightly divergent is the luminous image on screen D, whilst not a trace of phosphorescence is to be seen on the screen E in the other limb of the tube. Now I push the exhaustion to the highest point short of non-conduction (0.000076 mm., or 0.1 M.), and the phenomena change. The initial line of light on D becomes wider and unsteady, whilst at the gate, G, a decided phosphorescence is observable entering the second screen E. This luminosity diverges to a considerable extent, much more than did the stream of charged molecules observed in the first limb of the tube at the lower exhaustion.

THE RESISTANCE OF HIGH VACUA.

The passage of an induction current at a high vacuum through a tube depends much upon the material of the tube or the substance enclosed within it. Given the same degree of exhaustion, and the same distance between the terminals inside the tube, the E. M. F. necessary to force the current through may vary from 8,000 volts to 20,000 volts, according to the particular material used.

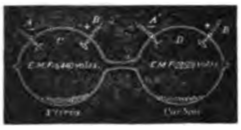

FIG. 27.—P = 0.02 mm. = 26 M.

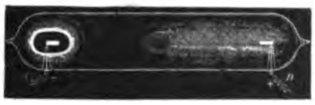

FIG. 28.

Here is a very striking example that will serve to illustrate this phenomenon. Fig. 27 is a double tube joined by a narrow open channel and therefore in the same state of exhaustion throughout (P = 0.02 mm. or 26 M). Each tube is furnished with a pair of poles, A, B, and A', B'. One tube contains the phosphorescent earth yttria, the other contains finely divided carbon. I first connect the yttria tube, C, to the coil, and place in parallel circuit with it a spark gauge. To begin with, this gauge is set to a gap of 1 mm. (An E. M. F. of 920 volts is necessary to strike across 1 mm. of air; therefore the difference of potential at the terminals inside the yttria tube is 920 volts, and this you perceive is not sufficient to force the current through the tube.) I now gradually open the gauge until the potential of the inner terminals has risen to a point high enough to allow the spark to pass through the tube, making the yttria phosphorescent.

The gap is at 7 mm., equal to an E. M. F. of 6,440 volts. I next attach the coil wires to the tube, D, containing the carbon, and the exhaustion in the tubes being the same as before, I repeat the experiment; you now see that the gap has to be opened to 30 mm., equivalent to an E. M. F. of 27,600 volts, before the current will pass through the tube. The fact of whether the vacuum tube contains yttria or carbon makes a difference of 21,160 volts in the E. M. F. required to cause a discharge between the terminals.

One other experiment I would like to show in further illustration of this resistance. The idea suggested itself that possibly differences in the material or conductivity of the particular bulbs might influence the results you have just seen. Here Fig. 28 is a long cylindrical tube of phosphorescent Bohemian glass containing a pair of terminals, A, B; it also contains a shorter cylinder of glass, C, C, brightly silvered inside. The internal pressure is 0.00068 mm., or 0.9 M. The silver cylinder is now at one end of the tube out of the way of the terminals, which therefore have phosphorescent glass around them. I turn on the coil and find that the E. M. F. necessary to force the current through, now that the terminals are in a phosphorescent chamber, is 1,380 volts. I slide the cylinder down to the end of the tube so as to inclose the terminals in a metallic silver chamber, and you see the E. M. F. necessary to pass the current rises to 6,440 volts. Metallic silver does not phosphoresce, whilst Bohemian glass phosphoresces very well. It appears that the greater the phosphorescing power of the substance surrounding the poles so much the easier does the induction spark pass. Surround the poles with Bohemian glass or yttria—two phosphorescent non-conductors of electricity—and the induction spark passes easily; immediately I surround the terminals with a non-phosphorescent conductor, the current refuses to pass.

WHAT OCCASIONS PHOSPHORESCENCE?

I should like to interest you in a question that has exercised my mind for some time past. What is it that occasions the phosphorescence of yttria and other bodies in vacuo under molecular bombardment?

So far I have found this phosphorescence to be an attribute of non-conductors only. We know that in the act of phosphorescence the molecules of yttria are in a state of intense vibration. Each molecule may be viewed as the radiating centre of the entire bundle of rays, which, when decomposed by the prism, displays a discontinuous spectrum. We may also suppose that the residual atoms of gas charged with negative electricity give off their electricity on coming in collision with a phosphorescent body and on their return take up a fresh charge.

THE ELECTROLYSIS HYPOTHESIS.

There is a certain amount of evidence in favor of an electrolytic hypothesis of the passage of electricity through rarefied gases. This has been ably advocated by Prof. Schuster in the Bakerian lecture before the Royal Society, March 20, 1890.

THE DARK SPACE IN MERCURY VAPOR.

In applying the electrolytic hypothesis, I have used for illustration's sake the gaseous residue of hydrogen, which is known as a diatomic gas. I have found, however, the phenomena of the dark space, etc., to occur in the vapor of mercury, which is a monatomic gas. This important result induced me to patiently investigate this subject, and the result of one experiment is before you, Fig. 29. The tube is furnished with aluminum terminals, and is so arranged that the induction spark can be kept passing during exhaustion to drive off occluded gases. When at the highest attainable vacuum, the tube is filled with pure mercury by simply raising a reservoir. On applying heat the entire contents of the tube are boiled away and pass down the fall tubes of the pump, exhaustion going on at the same time. When the whole of the mercury has thus been boiled away *in vacuo*, except a little, condensed at the upper part of the tube, the results on passing the spark are as follows: When the tube is cold the induction current refuses to pass; on gently heating with a gas burner the current passes and the dark space is distinctly visible. Continuing the heat so as to volatilise the drops of mercury condensed on the sides, the whole tube becomes filled with a green phosphorescent light, the dark space gets smaller and smaller, and ultimately the negative pole becomes covered with a luminous glow. On allowing the tube to cool, the same phenomena ensue in inverse order.

At first sight this result appears fatal to the electrolytic hypothesis, for if the molecule of mercury contains only one atom, how can we talk of its separation into positive and negative atoms by the electric stress? It must be remembered, however, that we are as yet ignorant of the absolute mass of the atom of any element. All that can be said is that a molecule of free hydrogen becomes halved in combining chemically with certain other elements, whilst a molecule of free mercury does not suffer division on yielding any known compound of mercury; the physical atoms in the one behave as two separate groups, and those in the other as one undivided group.

To show how intimately chemistry and electricity interlock, I may here remark that one of the latest theories in chemistry renders such a division of the molecule into groups of electro-positive and electro-negative atoms necessary for a consistent explanation of the genesis of the elements. This is so important that I may be excused for digressing a little into this development of theoretical chemistry.

FIG. 29.

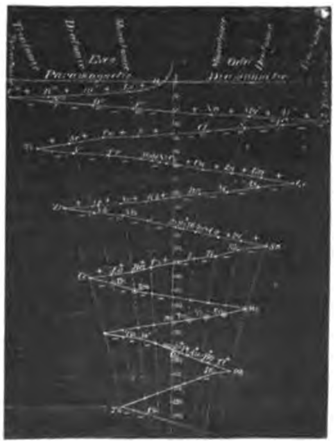

FIG. 30.

GENESIS OF THE ELEMENTS.

It is now generally acknowledged that besides the well-defined groups of chemical elements, there are underlying sub-groups. To these sub-groups has been given the name of meta-elements. The original genesis of atoms assumes the action of two forms of energy working in time and space—one operating uniformly in accordance with a continuous fall of temperature, and the other having periodic cycles of ebb and swell, and intimately connected with the energy of electricity (Fig. 30). The centre of this creative force in its journey through space scattered seed or sub-atoms that ultimately coalesced into the groupings known as chemical elements.

At this genetic stage the new born particles vibrating in all directions and with all velocities, the faster moving ones would still overtake the laggards, the slower would obstruct the quicker, and we should have groups formed in different parts of space. The constituents of each group whose form of energy governing atomic weight was not in accord with the mean rate of the bulk of the components of that group, would work to the outside and be thrown off to find other groups with which they were more in harmony. In time a condition of stability would be established, and we should have our present series of chemical elements, each with a definite atomic weight—definite on account of its being the average weight of an enormous number of sub-atoms or meta-elements, each very near to the mean. The atomic weight of mercury, for instance, is called 200, but the atom of mercury, as we know it, is assumed to be made up of an enormous number of sub-atoms, each of which may vary slightly round the mean number 200 as a centre.

This atomic scheme postulates a to and fro motion of a form of energy governing the electrical state of the atom. It is found that those elements generated as they approach the central position are electro-positive, and those on the retreat from this position are electro-negative. Moreover the degree of positiveness or negativeness depends on the distance of the element from the central line; hence calling the atom in the mean position electrically neutral, those sub-atoms which are on one side of the mean will be charged with positive-electricity, and those on the other side of the mean position will be charged with negative electricity, the whole atom being neutral.

This is not a mere hypothesis, but may take the rank of a theory. It has been experimentally verified as far as possible with so baffling an enigma. Long continued research in the laboratory has shown that in matter which has responded to every test of an element, there are minute shades of difference which have admitted of selection and resolution into meta-elements, having exactly the properties required by theory. The earth yttria, which has been of such value in these electrical researches as a test of negatively excited atoms, is of no less interest in chemistry, having been the first body in which the existence of this sub-group of meta-elements was demonstrated.

ELECTROSTATIC MEASURING INSTRUMENTS.[1]

THERE would seem to be some kind of prejudice against the use of electrostatic measuring instruments. Generally in an alternating current station, we find the high-pressure leads connected to transformers reducing to 100 volts or so, and a hot wire voltmeter employed to read by. The transformer takes, say, 30 watts, probably more, and the voltmeter another 30. This means 500 kilowatt hours per annum wasted. At 2½d. this comes to £5 a year, which is the interest on from £50 to £100. A laboratory electrometer was used in electric engineering by Joubert in 1881, and others have been used occasionally since by Professors Ayrton and Perry, Ryan and Monnier. Sir William Thomson has, however, introduced a number of electrostatic instruments, reading from 100 volts upwards, and engineers who use them do not revert to electro-magnetic or hot wire voltmeters. Electrostatic instruments not only take no power, but have no temperature errors, and do not need corrections for frequency, and no doubt they will eventually be cheaper than other forms. They cannot well be used as ammeters, but it is rumored—with what foundation we do not know—that Dr. Fleming will soon bring out an electrometer wattmeter. Of course, as shown by Professors Fitzgerald, Ayrton and Perry, a quadrant electrometer can be used to measure power, but unless the fall of potential over the shunt resistance in the current circuit is small, difficulties arise. Probably the electrostatic wattmeter of the future will have a split needle.

W. R. FLEMING & CO.

Messrs. W. R. Fleming & Co., selling agents for Harrisburg Ide and Ideal engines, boilers, etc., seem to be getting their full share of electric steam plant installation. Their claim to establish a leading business in these lines on reliable and conservative engineering work seems to be well founded.

During the past two weeks contracts have been made for the following plants: Messrs. Koch & Co., New York, one 90 h. p. and one 50 h. p. Ideal engine; Mt. St. Vincent, Central Park, one 20 h. p. Ideal; Heisler Electric Light Co., for town of Union, 200 h. p. Ide cross compound with boilers and complete steam plant; Pennsylvania Club House, Long Branch, 40 h. p. Ideal complete steam plant.

Several smaller orders taken make an aggregate of a trifle over 600 h. p. during two weeks.

Letters to the Editor.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER *150 Broadway, New York city.*

THE BERGMANN AMMETER.

On page 17 of your issue of Jan. 7, there appears a description of the new Bergmann ammeter. I take the liberty of drawing attention to the fact that I invented this type of ammeter as long ago as 1882 and patented it in Germany, the patent bearing the number 24,166, and the instrument being described in Figs. 6 and 7 therein.

F. UPPENBORN.

BERLIN, GERMANY.

THE MOST ECONOMICAL ARRANGEMENT FOR ELECTRO-DEPOSITION.

A few remarks from me upon Mr. Wilkes' "remarks" on my articles on Electro-deposition may possibly be of service in the cause of truth and justice.

I am sorry that Mr. Wilkes should have misunderstood my meaning when I said, "The polarization might also be expressed as a live or spurious resistance ρ, whose value is taken such that $C\rho = \varepsilon$." Perhaps he understood it to be a "dead", or ohmic resistance. Possibly he has never heard of the use of a fictitious (variable) resistance term, as an often convenient means to express loss of potential in circuits containing a counter electromotive force.

He does not think that the value of ρ could be separated from $(R+\rho)$. The relation $C\rho = \varepsilon$ points out a simple way by which it can be derived from his own method for obtaining ε. There it another simple way: from the potential difference at the terminals of the vat and the current passing through the vat, we obtain $\frac{E}{C} = R + \rho$. We then measure the ohmic resistance R, and subtract its value from $(R + \rho)$; or, $\frac{E}{C} - R = \rho$.

The product $C\rho$ gives ε as before. So far as practical accuracy is concerned this method will compare favorably with his method.

The equation in which ρ appears was only introduced as an alternative form. It is not numbered and is not again referred to at all in my articles. I can scarcely believe that Mr. Wilkes did not notice this; nor do I wish to suspect that he did not care to. However, he fails to do me the justice to admit that all the equations derived from (2) are unaffected in accuracy, and that the reasoning and conclusions hold good. As if to strengthen the impression conveyed, that my reasoning is all false, he proceeds to prove it again, by a method which differs slightly in detail from mine, principally because I wrote for the general reader and preferred to follow the longest, though most easy, "gradient" to the goal; I relied as much upon the logic of ideas expressed in words as upon that of ideas expressed in symbols, without any attempt at mathematical elegance or conciseness. I regret very much that Mr. Wilkes did not publish his demonstration *before* mine was published.

As to the value of n $(= 100)$ it was purposely taken large to make an extreme case and thus show more forcibly the relatively small increase in power as compared with one single vat. The term "actual data" refers, as might be inferred, to the values met in actual practice for polarization, resistance, current density, potential difference, etc., *per vat*. These data were, as a matter of fact, taken from plants working 85 to 70 vats. As for the comments on high voltage and current densities, I need only say that the articles treat of electro-deposition in general, and for all applications, of which refining is only one. My practical experience has embraced several of these applications, in some of which *speed*, in others, *economy* of deposition were prime considerations. The third article points out specifically that for refining, a low density is usually desirable and expedient.

The last "very prominent" point of dynamos referred to by Mr. Wilkes is almost humorous, considering that nine-tenths of the electro-deposition plants, even for refining purposes, use low potentials. The writer has himself used a dynamo giving 4,000 amperes at 10 volts. So far from "giving rise to no end of trouble," it never, so far as I now recall, gave any trouble whatever, during my experience with it of something like a year. It did not cost more than if wound for a higher E. M. F. Mr. Wilkes is evidently not aware, further, that the presumably oldest and largest electrolytic copper refining firm in this country has for years used, and so far as known, is still using, machines of over 4,000 amperes with an E. M. F. of 15 to 20 volts.

---

[1] *Industries.*

I do not wish to advocate extremes, particularly, but merely to show what has been, and can be, done. The medium course between the two extremes is the plan I would doubtless follow in practice. The 36 kilowatt machine of Mr. Wilkes, if put in under my specifications, would probably be of 20 or 25 volts—not more than 30—even though it could not be found in stock. I would suit my own requirements, not the convenience of the manufacturer. The difference in cost is not worth discussing.

C. O. MAILLOUX.

NEW YORK, Feb. 13, 1891.

AN INVITATION FROM CANADA TO THE N. E. L. A.

The winter convention of the National Electric Light Association about to be held in Providence, R. I., presents a most opportune occasion to renew the suggestion I had the honor to make while attending a convention of the association during the past summer at Cape May, N. J., viz., that the next summer meeting of this electrical fraternity be held in Montreal, Canada. To more fully impress this idea, then so flatteringly received, on the members of the association, I seek permission to use the columns of your journal, as I feel no better medium exists, to reach the members, widely separated as they are throughout every State in the Union, than by means of the papers particularly devoted to electrical pursuits.

To do this thoroughly, in view of the vast benefits to be derived by such a gathering in Montreal, to the electrical interests of the Dominion, I may perhaps have to trespass too much on your valuable space. I remember, however, that your principal object is the dissemination of the knowledge of the powers of electricity, and think the points I wish to cover in carrying out my idea, are to the benefit of Canada, and the profit and pleasure of the members of the N. E. L. A. and will prove of interest to the general reader.

First, then, to be considered are the benefits to be derived by Canada in general, and Montreal in particular, by the holding of the Convention here. It is well known that every member of the association is one who, if not himself an electrician, has the advancement of the science, and all things thereto pertaining, at heart.

Canada, and this I can say from a personal knowledge, is as yet to a certain extent a *terra incognita* to the several branches of electricity and the various uses to which this subtile power is put in the United States. True, many, perhaps nearly all, of the cities of any importance in the Dominion, are lighted by the brilliant rays of the electric light, but it is equally true, as I found during my many visits to the most important towns and villages outside of the cities, that there are hundreds of the former, so to speak, in the dark, but ripe for the reception of this great conqueror of the nineteenth century.

A few of the cities have adopted a system of electrical street railways, now in course of construction, for trial, but I believe that its use for the transmission of power from central stations, for manufacturing and other purposes, has not even been attempted. Certainly the science on this side of "line forty-five," is as yet in its infancy. Here, then, is a wide field for the "National Association." In this "virgin soil," a world of good can be done by holding one of its meetings among us, by showing the strength of its organization, by showing its influence, and by the power it can wield by letting Canadians hear the learned discussions on the many highly interesting and widely practical papers on many things pertaining to electricity, read at these semi-annual re-unions.

Canadians are naturally a slow people in grasping at a project which they do not thoroughly understand, unless assured by personal experience of its absolute success; but once this is instilled into their minds, it will be found that they are blessed with as much push and energy as the most energetic people the world over.

How better then can they be taught to enter into and utilize the full usefulness of this grand power that science has placed at their disposal, than by seeing and listening to the men of brains, of wealth, and of influence that are banded together in this great brotherhood, "The National Electric Light Association of the United States."

Through my several years' experience in connection with the electrical business in almost every part of Canada, I can probably gauge the feelings of the general public on these matters as well, if not better, than most, and therefore I know the vast majority are in favor of electrical advancement. I know further that all that is requisite for the formation of a *Canadian Association* on similar lines, which would give rise to electrical experiments throughout the Dominion, and a "boom," is the coming of our anticipated visitors. In using the word anticipated, I do so advisedly, for since my return from Cape May, I have been indefatigable in telling our people of the distinguished guests, individually and collectively jolly good fellows, in addition to their scientific worth, whom we might expect next summer. All classes, including the most influential men of our population, have received the information with every expression of delight. An official civic reception even would be probable, which, if given, would equal, if not excel, that tendered the visiting Iron and Steel Institute last year. One thing is certain, however, that should these electrical magnates, or the "*magnets*," with their lady guests, come, as all hope, nothing in Montreal will be too good for them and they may rest assured of receiving a true Canadian welcome.

So far I have spoken of the benefits to accrue to Canada by the holding of the Convention in Montreal. I will now say, in a few words, why it would be advisable to do so.

First: Montreal is within easy reach of every point in the Eastern, Western and Northern states. If approached by rail, there are a dozen different routes centering here with their connections, the principal of which are the Grand Trunk with its Chicago and Western connection, the Canadian Pacific with its St. Paul and Minneapolis branch; also in the East with the Boston Air Line, the Central Vermont, connecting with the Boston and Maine Central and New York Central, and the Delaware connecting with the New York Central. Special reduced rates over these several routes no doubt could, and would, be arranged for the members of the association. All the lines named run through parts of Canada where the scenery is of great and varied beauty. If by water, via the St. Lawrence route, on which ply the palatial boats of the Richelieu and Ontario Navigation Company, and by which the greater part of the trip could be accomplished, the visitors would enjoy the novelty of a semi-ocean voyage by the turbid waters of the rapids, and could return by the more rapid railways. In all probability the larger number of the members would select the journey by water, as in doing so they would have the pleasure, spiced by an infinitesimal degree of danger, of "shooting the rapids" of the St. Lawrence, including the greatest of them all, the world famed one of Lachine. Before these would be reached, however, they would enjoy that grandest of all pieces of Canadian water scenery, a trip through nature's marine paradise, the Thousand Islands.

This route would also take the visitors over the Gallop, Coteau and Cascade Rapids, and through a variety of picturesque scenery.

But besides the pleasures of the St. Lawrence route and its famous Rapids, the trip will have even so far proved one of profit to the members of the association. It will by actual experience have given them some idea of the magnificent and almost totally unused water power of Canada. It will offer them food for reflection, and no doubt a worthy subject for subsequent discussion as to how this power could be best utilized as a motive force for electric lighting and other purposes to which electricity can be put. At present there is a somewhat, as yet, chimerical scheme afoot here to obtain the rights of the Lachine Rapids so as to utilize the current as motive power for many different purposes. The members of the association can visit the scene easily from Montreal, and decide how far the scheme is feasible.

One scheme of this great proposed undertaking proposes utilizing the power at "Isle-Aux-Herons," a small island directly at the foot of the Lachine rapids, which no doubt would be noticed by the excursionist to the north of the steamer as she wends her swift way to the city. This island has been divided by nature into two parts, and through the channel thus made runs a current of tremendous velocity. This island has been purchased by a strong syndicate, who propose to obtain one hundred thousand horse power or more, at this point, not alone by the facilities offered by the island, but by damming the north channel and thus obtaining the enormous energy of the rapids. This it is proposed to transmit by electricity to Montreal, four miles distant, for use there and in the surrounding districts. The only difficulty in the way of this is our annual Spring and Fall inundations, which, by the backing up of the water at the foot of the rapids, would materially affect this power. Able engineers are now at work trying to solve this difficulty, and strong hopes are entertained that it will soon be overcome; in fact, many experts favor a plan of flood prevention, which I have proposed myself and had under government consideration, and which the said experts claim would, by carrying off the surplus water of the ice-jammed river, answer every purpose.

No matter the way; let this difficulty once be surmounted, and Montreal and the surrounding country will have a motive power which will be one of the scientific wonders of the century, and which could never be obtained except through the power of electricity.

Then Montreal! As I have shown, the members will be received with open arms. There is no more beautiful city in America. Its manufactories, its public buildings, its historic relics, its scientific observatories, its magnificent churches, and last, but not least, the works for the manufacture of electrical apparatus, and the stations for lighting the city, are places of interest too numerous to mention in the space of a communication; but they are all worthy of visits, and will prove sources of pleasure and delight.

As to accommodation, the members of the association need have no cause to fear. Our hotels are among the finest in America, and the palatial Windsor, and the favorite St. Lawrence Hall have obtained a world-wide reputation.

There are many large halls, particularly that attached to the Windsor hotel, any one of which would be suitable for the business meetings of the convention, while there are equally commodious buildings suitable for the electrical exhibitions that are always held at these meetings of the association. On the occasion, which I hope will come, Canadian inventors and manufacturers in this line can exhibit side by side with those of the United States.

I think that above, I have given sufficient reasons why it will be in the interests of the association to hold its next Summer convention in this city, which is within easy reach of many other places of interest to the visitor, including Quebec, the Montmorency Falls, and such favorite resorts as Reviere du Loup, Murray Bay, Cacouna, etc.

Surely I have written enough to show that the association, so soon to be in conclave, should fix on Montreal as their next place of meeting; and why? Because I only voice the sentiment of Montreal's people when I say that it should be so.

In writing as I have, I did not wish to dwell too much on my country's merits, but simply to impress on these gentlemen, these Knights of Electrical Science, with ladies fair, the pleasures as well as scientific profit to be gained by holding the annual summer convention of 1891 of the National Electric Light Association of the United States in this city.

A word in closing, Mr. Editor, to the gentlemen of the association: Come one and all, and I can assure you once more a hearty welcome from the citizens of Canada and of Canada's metropolis! ALBERT J. CORRIVEAU.

MONTREAL, QUE., Feb. 3, 1891.

LONDON.

Paris Meter Competition.—Perreur Lloyd System in the Law-Courts.—Professor Ayrton on Disturbances.—Union of Munich and Berlin.—Acceleration.—Paris and London Telephone.—Electric Lock and Block System on the South London Railway.

IT is said that the Paris Electric Meter Commission has entered upon its duties of testing the seventy-one different kinds of meter sent in. The following is a list of the officiating judges: MM. Carpentier, Chretien, Hospitalier, Huet, Laffargue, Lemoine, Mascart, Meyer and Potier.

A fugitive system of generating electricity called the Perreur-Lloyd, which dazzled the vision of the City Commissioners here some time ago, has "o'er leaped itself" and fallen into the law courts. The Perreur-Lloyd system consisted in the erection of works for the manufacture of chemical products—sulphates, simple or double chlorides of copper, iron, zinc, manganese, nickel, etc.—in which electricity was considered only as a self-product. The claims were proved to be baseless. Notwithstanding, however, the condemnatory opinion of experts, an attempt was made to float a company for the purpose of foisting the rubbish on the English market. With this end in view, a Mr. Vesey induced two Yorkshiremen, on the plea that electricity could be produced for nothing, to place at his disposal £5,000. As no return was apparent, suspicions were aroused and an action was brought for the recovery of the amount. The jury entered a full verdict against the defendant.

Professor Ayrton in a letter to the *Times* discusses the probable effect of the proposed electric railway (subway) between Paddington and South Kensington on the laboratories of the Central Institution which are situated on the intended line of route. The Professor states that during the past few weeks Professor Rucker and himself have been taking measures to ascertain the magnitude of the disturbance that will be caused by the railway. They did not employ very delicate instruments, but the ordinary rough apparatus that is in daily use by students in a modern physical laboratory. This, however, was seriously affected by mechanical vibration, and they were led to the conclusion that the earth waves produced by the passage of large weights at high speeds impaired the measuring instruments. According also to the observations made, electrically propelled tramcars constantly passing within a few yards of the Physical Laboratory would make even rough electrical measurements absolutely impossible, and if the scheme is carried out it will entirely spoil one branch of the technical instruction which is now given.

The project of uniting Munich and Berlin by means of an underground cable was recently introduced in the Bavarian Legislature. All that is necessary is the laying of a cable to the Bavarian frontier town of Hof, where it would connect with the cable of Dresden, which is a continuation of the underground telegraph line from Berlin to Dresden.

In 1876 a test line was laid from Berlin to Halle, a distance of 169 kilometres. At the close of 1883, 30,000,000 marks had been expended in the development of an extensive underground telegraph network.

On the occasion of the forthcoming celebration of the German Emperor's birthday, there will be a display in Berlin of 25,000 electric glow lamps specially installed for outside illumination.

The cold weather has delayed the progress of the laying of the Paris–London telephone wire, in consequence of which, it will not be used until the first of March. The fifteenth of February is the date fixed for the submersion of the cable. The official's test will last until the end of the same month. The tariff has been fixed at 10 fr. for three minutes' use of the telephone. It is said that Queen Victoria and President Carnot will speak the first message.

Last Wednesday evening Mr. Spagnoletti, M. I. C. E., read a paper before the Inventors' Institute on the electric locking and block system as applied on the City & South London (Electric) Railway. Mr. Spagnoletti after a concise description of the construction of the line fully explained and described the working of the electric locking system as applied to both double and single lines. The lever of the starting signal is always kept locked to "danger," and before a signalman can possibly pull it over to lower the signal arm for a train to leave his station he must send a bell code to the next station in advance to unlock his lever.

This can only be done by the man at the station in advance sending a current of electricity by an instrument in his signal box, and the act of sending this current locks up his instrument, so that he cannot possibly send another until the train arrives at his station, and passes the clearing point, when it passes over a contact maker and resets his instrument, so that it can be worked again for a second train, but not until the first train has arrived and the section is clear. When the signal arm has been unlocked and lowered for a train to proceed, after its departure it must be replaced to danger, and it cannot be lowered a second time until the lever has again been unlocked from the station in advance and the station in advance cannot again unlock until the train occupying the section has cleared it, and reset his instrument to enable him to do so. This piece of automatic working which gives no signal itself, forms a thorough check upon the signalman and prevents him making any mistake from any misapprehensions he may have in his mind. It simply resets the instrument to enable him to work it again, and checks him if he should attempt to work it at a time when he ought not to do so before the section is clear. When the starting signal lever has been lowered for a train to leave, it must be put back again, or the signalman cannot take the lock off for a following train coming from the station in his rear.

In working single lines, when taking the lock off at either end from the opposite end of the single line section for a train to proceed, the act of releasing the lock at the other end, locks up the instrument and severs the wire which conveys the current to the lock in either direction, so that it is impossible to take the lock off again at either end until the train occupying the section has arrived at the proper place in whichever direction it is going, and resets the instrument and re-establishes the circuit.

When the lock has been taken off by the station in advance for a train to proceed over the section, and the train from any cause should not proceed, the signalman is compelled to move his lever and lock it before he can take the lock off at the other end for a train coming in the opposite direction.

Mr. Spagnoletti also pointed out that in working junctions one instrument only is required, as by means of a switch any number of line wires connecting the next stations on the various branches can be joined to this one instrument without affecting the safety of the working.

In crossing trains from one road to the other, he explained that when the levers affecting the cross-over roads were unlocked, trains could not be allowed to approach the station on either the up and down line and vice versa. He pointed out that a section might be divided into two sections and yet be worked by the same signalman, by having an intermediate signal locked from the same signal box, so that the one signalman could work both sections, first taking off the lock at the station in the rear for a train to proceed to the intermediate signal fixed at a certain point, which signal lever can only be unlocked by himself when the second section is clear, thus saving the expense of an extra signal station and staff to work it.

On local lines where trains stop at every station, there is no need for fogmen in foggy weather, because no train enters a section until it is quite clear, and the train itself controls the working of the section. Should any derangement occur to the instruments in the working, the safety of the system is not affected, neither is any delay to the traffic caused, because the derangement locks everything up on the side of safety, and the instrument can be moved by hand as well as by the treadle, under the guidance of the inspector or other authorized person, when any derangement may occur. This system does not relieve the signalman from any of his present responsibilities, it simply checks him from doing wrong if he should attempt to do so, and prevents him from working the signals when he should not do so. This system is at work on many lines and is giving every satisfaction.

It is a system which will no doubt grow as it becomes better known and understood, and it is one which evidently will very greatly add to the safety of railway working. Diagrams and working instruments were exhibited and explained.

A New Mast Arm.—Electric Railway Notes.—Report of the Allegheny County Electric Light Co.

THE Allegheny Committee on Public Lighting has under consideration the advisability of adopting a newly patented mast arm for electric lighting of the streets. One of these mast arms is now being erected on trial. This arm is different from some of the others in that it does away with the necessity for climbing the pole, and when the lamp is lowered for cleaning and changing carbons there is no danger to passing teams. At the base of the pole is a locker, in which is the crank with which the lamp is lowered. This also provides a place for storing carbons and tools. The lamp when lowered is first drawn to the pole, then it comes down in a straight line. A man named Carlisle, who resides in Lawrenceville, this city, is the patentee of this mast and arm.

The Citizens' Traction Company, of this city, has just made a contract with a local electric light company, for the lighting of their power-house and the vaults of their cable road.

One of the Allegheny electric street railway lines suffered a few days ago from a landslide, which did considerable damage to the tracks of the line. The Bellevue Electric Railway runs for a distance along the brow of a hill. The recent excessive rains, however, caused the ground above the tracks to loosen and at last it gave way altogether. The land came down with great force, carrying quite a portion of the track in its path and leaving the rails suspended in the air. Fortunately, no car was passing there at the time. The damage to the track will be immediately repaired.

The annual meeting of the Allegheny County Electric Light Co. was held in the company's office in the Westinghouse building a few days ago, and the following board of directors was chosen: George Westinghouse, Jr., A. M. Byers, Robert Pitcairn, C. L. Magee, T. Sproull, Wm. Eberhardt, J. E. Ridall, G. H. Blaxter. Owing to the absence of Mr. Westinghouse, the organization of the board was deferred until his return from the East, where he now is in connection with the plan of placing 40,000 shares of preferred stock of the Westinghouse Electric and Manufacturing Company. The financial statement for the year 1890 was read to the meeting, containing the following interesting items: The earnings for the year were $310,256.24; operating expenses, $199,041.77; earnings over operating expenses, $111,214.47; less interest on bond and mortgages interest on discounts, $44,025.41; net earnings, $67,189.06. The comparative statement of electric lights operated by the company for the last four years is very interesting. It shows that in 1887 the number in use were 10,511; in 1888, 20,145; in 1889, 27,829; in 1890, 33,500. The number of arc lights operated by the company in 1890 amounted to 857. Since the first of December last, applications have been made to the company for the placing of 2,000 additional incandescent lamps.

PITTSBURGH, Feb. 13, 1891.

BOSTON.

Municipal Ownership of Lighting Plants.—An Underground Road.

THIS week the committee on manufactures continued the hearing on the question of municipal ownership of gas and electric light plants. Mr. Sylvester Baxter argued in favor of such control, claiming that private management tended towards concealing the profits, and imperfect lighting on moonlight nights, and after midnight, and that the business could be much more honestly managed under municipal control.

Mr. Baxter was cross examined by Mr. E. Burdett and Hon. P. A. Collins, who aimed to show that gas and electric light companies were conducting their business in the interests of the public.

In the common council the following orders were passed:

> That the mayor be requested to petition the General Court for such legislation as will authorize the city of Boston to construct and mantain such elevated railroads as the city council, with the approval of the mayor, may from time to time adjudge to be required for the convenience and necessities of the inhabitants of this city.
>
> That the mayor be requested to remonstrate against the granting, by the Central Court, of the petitions of any private persons or corporations for leave to locate elevated railroads in Boston, until the petition of the mayor, as above provided, is finally disposed of by the Legislature, or until authority has been granted to the city of Boston to exact compensation for the use of its streets by persons or corporations.

Boston is agitating an underground railway, and a hearing was given this week at the State House by the committee on street railways on the petition of Mr. H. C. Spaulding for permission to build subterranean railways in the counties of Suffolk and Middlesex. Mr. H. M. Whitney, in replying to Mr. Spaulding, maintained that if underground roads were built they should be constructed with reference to the surface roads, and that electricity should be the motive power.

BOSTON, Feb. 14, 1891.

CHICAGO.

Arc Lamp Litigation.—A Charter Revoked at Omaha.

THE contest over the electric arc lamp patent between the Brush Electric Company and the Western Electric Company is going on before Judges Gresham and Blodgett. Not long back the Brush Company secured an injunction restraining the Western Electric Company from infringing the patent. The Western Electric Company seeks a dissolution of the injunction on the ground that the Brush Company is interfering with a speedy trial in the United States Supreme Court. A counter motion is made by the Brush people to have the Western Electric Company attached for contempt of Court in violating the restraining order.

At Council Bluffs, Ia., a bitter fight has broken out between the city and the Omaha and Council Bluffs Bridge and Motor Company, of Nebraska. The above-named company some while ago absorbed all the street railway and motor lines of the city and operates now some 20 miles of lines of which about one-half is on paved streets. The company now in control absolutely refuses to pay grading and paving assessments and also refuses to pay property owners on streets where lines were laid after paving was completed. Last week the City Council passed an ordinance through under a suspension of the rules rescinding the charter, and later the city attorney commenced some half dozen suits against the company for various amounts for intersection, grading and paving.

CHICAGO, Feb. 12, 1891.

THOMSON SCIENTIFIC CLUB, LYNN, MASS.

The members of the Thomson Scientific Club were entertained at their last meeting, Feb. 5, by a very interesting talk on "The Copper Mines of Lake Superior" by Mr. C. H. Veeder, who spent about two years in that region.

The club is now settled in its new home in the two upper floors of the new building on the corner of South street and Western avenue, West Lynn, and within a few moments' walk from the Thomson-Houston Co. and Welding Co.'s factories.

The new quarters consist of a library, billiard and card room on the first floor, and a large well lighted hall on the second floor for lectures, besides committee room and janitor's quarters.

At a recent election, the following officers were elected for the ensuing year: President, J. E. Randall; 1st vice, J. B. Cahoon; 2nd vice, H. G. Reist; secretary, Franklin Sheble; treasurer, John B. Barr.

With an executive committee and sub-committees to regulate the various departments, the club has a very able list of officers, and although young, the Thomson Scientific Club is very prosperous and has a bright outlook.

Financial Market.

Reports of Companies.

ELECTIONS.

Lowell, Mass.—At the annual election of the Middlesex Electric Light Company, the following officers were elected: Clerk and treasurer, John H. McAlvin; directors, George W. Fifield, W. A. Ingham, John H. McAlvin, Louis I. Fletcher, Cyrus Conant, James H. Tolles and Charles S. Collins. At a subsequent meeting of the directors Mayor George W. Fifield was chosen president and W. A. Ingham, vice-president.

Lowville, N. Y.—At the annual meeting of the Lowville Electric Light and Power Company, the following officers were elected for the ensuing year: George D. Jackson, president; M. A. Stoddard, vice-president; John D. Moore, secretary and treasurer; R. P. Grant, G. M. Skinner, J. L. Bush, W. H. Morrison, John D. Moore, Morgan A. Stoddard, George D. Jackson, F. C. Schraub, directors.

Somerville, Mass.—At the annual meeting of the Somerville Electric Light Company, the following officers were elected for the ensuing year: H. C. Buck, clerk; F. S. Pearson, treasurer; directors, David Cummings, F. S. Pearson, J. Henry Fletcher, H. M. Moore, R. E. Nickerson, W. L. Hooper, L. E. Merry, and George B. Neal, treasurer of the Charlestown Gas Company. President Capen, who has been the president of the company since its organization, declined re-election as a director, as did also Dr. A. H. Carvill.

Detroit, Mich.—The Detroit Electric Light and Power Co. has re-elected its old officers and board of directors, with the addition of W. S. Crane and Ralph Phelps, Jr., as new directors.

Portland, Me.—At the adjourned annual meeting of the Consolidated Electric Light Company the old board of officers was re-elected with the exception of the clerk, Mr. Clarence Hale, who declined a re-election, and Mr. George E. Raymond was chosen in his place.

Newburyport, Mass.—The Newburyport Gas and Electric Company has elected the following officers for the ensuing year: President, E. F. Stone; directors, E. F. Stone, W. H. Swasey, Eben Sumner, L. B. Cushing, T. C. Simpson, William R. Johnston, Albert C. Titcomb; treasurer, D. D. Tilton; auditor, W. E. Chase. The usual semi-annual dividend of 3 per cent. was declared.

Northampton, Mass.—The Northampton Electric Company has elected the following officers for the ensuing year: President, A. McCallum; treasurer, C. H. Pierce; directors, S. B. Fuller, H. A. Kimball, A. McCallum, E. C. Davis, C. H. Pierce. A dividend of five per cent. was declared.

Seattle, Wash.—The stockholders of the Home Electric Company have elected the following trustees: Isaac Dobson, C. P. Stone, E. C. Kilbourne, Angus Mackintosh and D. B. Denton.

STOCKS AND BONDS.

Boston, Mass.—The United Electric Securities Co., A. A. Glasier, treasurer, has invited sealed proposals from the holders of its collateral trust sinking fund five per cent. bonds, first series, for the sale to the company of $100,000 of said bonds. The bonds were to be taken up last week and paid with accrued interest to February 16.

Bellevue, O.—It is proposed by Bellevue, O., to issue $20,000 worth of bonds for electric lighting.

DIVIDENDS.

Laramie, Wyo.—The Laramie Electric Light Company has issued its 4 per cent. dividend warrants for the half year.

The Holtzer-Cabot Electric Co., Boston, Mass., G. E. Cabot, treasurer, has declared a dividend of $4 per share, payable February 15.

Hartford, Conn.—The Hartford Electric Light Company has declared the usual semi-annual dividend of 3 per cent. payable on demand.

Peoria, Ill.—Henry Scearer, city electrician of Peoria, has been arrested for the robbery of a safe. The arrest has created surpise, as the prisoner has always borne an excellent name and has been high in official circles for years. He has confessed the crime and turned over $500 of stolen money. In cutting out a pane of glass in the rear of the building he broke his knife and cut his hand, then climbing in the window he dropped the knife and these clues led to his arrest. Scearer assigns his downfall to drinking and gambling.

Society and Club Notes.

INSPECTING THE BROOKLYN EDISON PLANT.

Nearly one hundred of the members of the department of electricity of the Brooklyn Institute responded to an invitation given by Superintendent William S. Barstow, of the Brooklyn Edison Illuminating Company, to visit the company's station at 360 Pearl street, on Feb. 7th. Among the number were several of the prominent electricians and mechanical engineers of Brooklyn. The party was divided into five sections, under the special care of Superintendent William S. Barstow, R. Lindsay, R. S. White, T. L. Clarke and J. L. Becker. A very enjoyable evening was spent.

RAPID TRANSIT AT THE NEW YORK ELECTRIC CLUB.

The next regular meeting of the Club will be held at the Club House on Thursday evening, February 26th. A dinner costing $3.00 per plate (exclusive of wine) will be served promptly at 6:30. The topic for discussion will be Rapid Transit for Cities. The Mayor of New York, members of the Rapid Transit Commission and a number of prominent men from various parts of the country actively interested in cable, steam, electric and horse street railway work, will be invited to be present as guests of the Club and participate.

Members desiring to be present at the dinner must notify the secretary, on or before February 23, in order that provision may be made for their comfort. As only about 100 can be seated at table, the custom of giving each member the privilege of inviting a guest will have to be suspended. Applications for the privilege may, however, be made to the secretary and will be granted in the order of their receipt by him, and as far as the Club's accommodation will permit.

At this meeting, in pursuance of a notice given at the last regular meeting of the Club, action will be taken on the following proposed amendment to the By-Laws:

"To add the following to Article IX to be called Section 2.

"Any By-Law may be suspended for a period not exceeding three months by a majority vote of the Active Members present at any regular meeting or adjournment thereof, or by a two-thirds vote of the Active Members present at any special meeting."

And in case the same should be acted upon favorably, a resolution will be submitted to suspend for three months that portion of the By-Laws which fixes the initiation fees for Active and Associate Members, and to admit new members during the same period on the payment of one-half of the regular initiation fee.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

A meeting of the Institute will be held on Feb. 24, at 8 p.m. at the house of the society, 12 West 31st street. Mr. Frank L. Pope will exhibit a most interesting electrical relic in the shape of one of the model electric railways made by Thomas Davenport, over fifty years ago. Mr. Pope will make a brief address on the subject. He will be followed by Mr. Oscar T. Crosby, who will read a paper entitled "Data and Results of Experiments with Electric Traction at 120 Miles an Hour," embodying his own experience and calculations in this novel department of applied electricity.

Legal Notes.

Saginaw, Mich.—Last May, the Michigan Central Railroad Company cut the overhead wires of the Electric Street Railroad Company on South Washington avenue, Saginaw. The street car people sued for $20,000 damages in the Circuit court, and were recently awarded $933.03 and costs.

THE ELECTRIC RAILWAY PLANT AT LOS ANGELES, CAL.

The Edison General Electric Company has sued the Electric Rapid Transit Company to recover possession of an electric plant used in the operation of a street railroad in Los Angeles, or for $50,000, its value, with $40,000 damages for its alleged unlawful detention.

Appointments, Etc.

Mr. Harvey D. Reynolds, for several years manager of the Buffalo business of the Postal Telegraph Company, has been appointed superintendent of the fifth division, including all the lines between Ogdensburg, Syracuse, and Cleveland.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED FEB. 10, 1891.

Accumulators :—

Electrode for Secondary Batteries, M. M. M. Slattery, 446,104. Filed April 6, 1889.

Claim 4 follows :

In a secondary battery, a porous copper electrode consisting of fine copper powder strongly compressed into a coherent body, an alkaline solution, and another electrode of zinc, iron, or other metal.

Alarms and Signals :—

Electro-Mechanical Indicator for Fire-Alarm Telegraphs, T. F. Gaynor, 445,991. Filed May 15, 1890.

Relates to indicators of the class in which a series of figured drums are actuated through electro-magnets and intermediate mechanism to display the requisite signals or indications.

Multiple Call-Box, F. B. Wood, 446,199. Filed Jan. 6, 1890.

A multiple call-box adapted to give, when operated, and without disturbing the central station instruments, an audible test signal to inform the person operating the box that the circuit over the line is complete, and adapted also to receive return-signals from the central station.

Fire Indicator and Extinguishing System, S. Broichgans, 446,200. Filed Oct. 29, 1890.

An apparatus, in connection with thermostats and automatic sprinklers, adapted to give an alarm locating a fire and indicating the turning on of water at the automatic sprinkler through an indicator at a central station or at the office of a building.

Conductors, Conduits and Insulators :—

Electric Insulator, J. R. Branch. 445,969. Filed May 20, 1890.

Designed particularly to prevent the impairment of insulation through the running of water down the insulator in wet weather. A section of insulating material to embrace the conductor, and adapted to be secured to the top of the insulator proper, is provided. The insulator has a flat base to be secured upon a support, is circular in cross section and is provided with a peripheral overhanging edge or drip.

Method of Laying Electric Cables, C. H. Wilson, 446,214. Filed Sept 19, 1889.

A device for adjusting a number of cables in position after they have been drawn into a conduit, and adapted to arrange them symmetrically and compactly. Consists substantially of blocks or wedges adapted to be drawn through a conduit to arrange the cables already drawn in and to clear a passage for the drawing in of additional cables.

Distribution :—

System of Electrical Distribution for Mines, E. A. Sperry, 446,080. Filed Apr. 1, 1889.

Claim 1 follows :

In a system of electrical distribution for mines, the main conductor leading down the main entries, branch conductors leading down the butt-entries derived from said main conductors, and ammeters located at the junctions thus formed, in combination with machines for both mining and transporting, deriving their energy from the same wires.

Automatic Potential Regulator for Electric Currents, A. L. Ellis, 446,284. Filed July 3, 1890.

Consists in the combination with a potential-regulating device, of a pair of electric motors connected with the potential-controlling devices and with the main circuit, and a circuit-controlling magnet and armature arranged to send the current to one or the other of the motors, and so operating the potential-controlling devices according to the requirements of the circuits.

Dynamos and Motors :—

Dynamo-Electric Machine and Electric Motor, E. K. Brown, 446,092. Filed Nov. 1, 1889.

Relates to the design and construction of field magnets and pole-pieces and particulary to those that are laminated.

Regulator for Electric Motors, L. S. Harris, 446,229. Filed Aug. 30, 1890.

For the regulation of constant potential motors. Has field magnets wound with a shunt-circuit and armature wound with another shunt-circuit ; has also independent circuits in parallel-arc, of different sizes and lengths of wire, passing over the field-magnets and directing their current thence over the armature circuit, with switch mechanism for bringing the latter shunt-circuits successively into, and out of, action.

Lamps and Appurtenances :—

Extensible Bracket for Electric Lamps, J. E. Titus, 446,087. Filed Mar. 14, 1890.

Design and construction for a drop-light chandelier.

Electric-Arc Lamp, R. H. Mather, 446,108. Filed Jan 24, 1887.

A focussing arc lamp. In connection with two carbon-carrying slides employs a reversible electric motor, intermediate converting mechanism whereby the motor engages the slides, a three point pole changer controlling the motor and having two helices located in shunt-circuit about the carbons, and a lifting-magnet provided with a circuit-breaking mechanism applied to one of the shunt circuit.

Arc Light, R. H. Mather, 446,109. Filed Oct. 11, 1886.

Similar in scope to No. 446,108 above.

Electric Signal and Search-Light Lantern, G. W. Martin, 446,142. Filed Feb. 28, 1890.

Details of lantern for reflecting and directing the light of an incandescent lamp.

Insulating Coupling-Block and Cut-Out, S. Bergmann and C. J. Klein, 446,180. Filed Mar. 11, 1890.

A combined coupling-block and cut-out adapted to connect an electric light fixture to a gas pipe.

Electric-Arc Lamp, C. J. Schwarze, 446,297. Filed Oct. 2, 1890.

A focussing arc lamp.

Arc-Light System, C. J. Schwarze, 446,298. Filed Oct. 9, 1890.

A system of circuits for arc-lights in series.

Miscellaneous :—

Electric Switch, E. A. Sperry, 416.081. Filed July 2, 1890.

A double circuit-closer and breaker actuated by a rotating cam.

Lightning-rod, G. W. Downey, 446,130. Filed Oct. 15, 1890.

Comprises a strip of sheet copper angularly bent and twisted into spiral form.

Electric Cooking Apparatus, J. O'Meara, 446,174. Filed May 1, 1890.

Surrounds an enameled cooking vessel with coils of German silver or other wire and surrounds the wire with an insulating covering.

Automatic Weighing-Scale and Indicator, A. B. Rover, 446,208. Filed Sept 27, 1890.

Electro-magnetic apparatus employed for arresting the traveling poise and indicating the figures of the scale.

Heat-Regulating Apparatus, G. L. Shorey, 446,212. Filed Apr. 28, 1890.

A combination of fluid-pressure and electro-magnetic apparatus with a thermostat for heat regulation.

Railways and Appliances :—

Switch and Signal Apparatus, G. Westinghouse, Jr., & J. G. Schreuder, 446,159. Filed March 19, 1888.

Relates to interlocking mechanism for controlling by fluid pressure and electro-pneumatic pressure, appliances for moving switches, signals or other similar devices at a distance, where a return indication of completion of the movement is desired, and where the completion of such movement effects a locking of the controlling magnet.

Electric Locomotive, G. R. Baldwin, 446,245. Filed July 17, 1890.

Relates to mounting of motors on electric car trucks and gearing them to the driving axles. Armature shaft is longitudinal with the car truck, its pinion driving a gear wheel upon a central shaft extending to both axles and connected to them by beveled gears.

Electric Signal System for Railroads, E. C. Wiley, 446,318. Filed Nov. 13, 1890.

A track circuit-closer to be actuated by passing trains.

Electric Railway and Contact Device Therefor, E. M. Bentley, 446,376. Filed Sept. 20, 1888.

Details of contact-device for conduit electric railway system. The contact is substantially a two wheeled trolley.

Track Instrument for Railway-Signals, M. S. Conly, 446,403. Filed June 5, 1890.

A track-instrument to be actuated by passing trains and adapted to either open-circuit or closed-circuit signals.

Telephones and Apparatus :—

Telephone Transmission, J. W. McDonough, 446,188. Filed Aug. 28, 1885.

Substitutes for the induction coil usually employed, a dynamo the field-coils of which are connected with a michrophone transmitter and a suitable source of electricity ; the armature, revolved by any suitable power, is connected in line with the receiver.

Claim 1 follows :

The herein-described method of transmitting sounds electrically consisting in producing changes in the intensity of a magnetic-field corresponding to the character of the sound vibrations, revolving a magneto-electric armature in said field by any suitable power, and delivering the variable currents as produced to a suitable receiving instrument.

Personal.

GEORGE W. STOCKLY.

The recent sale and transfer of the business interests of the Brush Electric Co. has afforded a much desired opportunity for some of the officers who have been connected with it from the beginning to enjoy a well-deserved vacation. No small share of the brilliant success which has been achieved by this company is due to the enterprise and sagacity of its managers, and especially of its retiring president and business manager, Mr. G. W. Stockly.

Mr. Stockly is a native of Cleveland, Ohio, and studied for the legal profession, but was forced by circumstances into the vocations of commerce and banking. In 1873 he became financially interested in the Cleveland Telegraph Supply and Manufacturing Co., and subsequently, by the death of his associates, the entire management of the concern unexpectedly devolved upon Mr. Stockly. Although possessing at that time scarcely any technical knowledge of the electrical business, he proved himself equal to the emergency. In a very short time he made himself master of the situation, and the business of the company prospered accordingly. In 1876, a chance conversation between Mr. Stockly and Mr. Brush in reference to the Gramme and other dynamos, led to an expression of opinion by Brush that much more efficient machines might be made. This idea was eagerly taken up by Stockly, who offered the facilities of his factory and selling organization for securing the introduction and sale of such a machine, if it could be made. This led to the development of the celebrated Brush dynamo and Brush arc lamp, and under Mr. Stockly's energetic management the business ultimately grew to enormous proportions. In 1878 the total sales of the company were less than $50,000. By 1883, they had increased to $2,000,000. In 1880, the company was reorganized under the name of the Brush Electric Co., and since that time, its record has been that of continuous and unbroken success. It is understood that the purchase by the Thomson-Houston Co. was made on a basis of over $3,000,000 for the capital stock of the Brush Company.

Mr. Stockly is to be congratulated upon the wisdom of his decision to withdraw, at least for a time, from active business pursuits, and to enjoy the leisure which he has so well earned. He is now living in a retired but beautiful place at Lakewood, N. J., but no doubt still finds something to interest him in the successive movements upon the electrical chess board. There are few men to whom the electrical industries of the present day are more indebted than to Mr. Stockly, and the good wishes of all will follow him in his retirement from the arduous post of duty which he has held so long and so successfully.

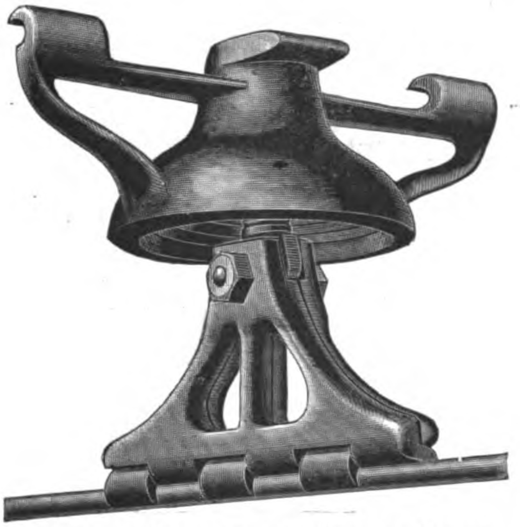
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

"Conventions come and conventions go, but an 'ad.' talks on forever."

A NEW TROLLEY WIRE HANGER.

We show in the accompanying engraving a purely mechanical device for hanging trolley lines, designed to facilitate overhead construction, and to make it possible to adjust the hanger easily to any stretching or contraction of the trolley wire. By the use of this hanger one man can shift several miles of hangers in ten hours. As will be seen in the cut, the device, though it can be so readily applied and removed, offers a firm support to the wire, as by tightening the bolt at the top, the grip of the tongs can be made very great. The clamp screws into plates imbedded in vulcanized rubber, which forms the insulating medium, and which is protected by a metallic shell. The hanger is attached to the span wire in the manner now in common use, which has proven so satisfactory. It is one of the new articles brought out by the Electrical Supply Co., of Chicago.



"Hercules" Hanger for Trolley Wires.

THE "A. B. C." INCANDESCENT LAMP.

It is rare that a new invention, or an improvement on an old invention, becomes so favorably known and so generally adopted as has the "A. B. C." incandescent lamp. Prior to the autumn of 1890 there was no "A. B. C." lamp, though its sponsors were well and favorably known. Within a period of four months the "A. B. C." lamp has been adopted by many of the largest central stations throughout the country; it is shining in the streets of the principal cities, in the mills and factories of New England, the Middle States, the South and the West, and in the large office buildings whose tenants enjoy the advantages of electrical illumination.

The "A. B. C." Incandescent Lamp.

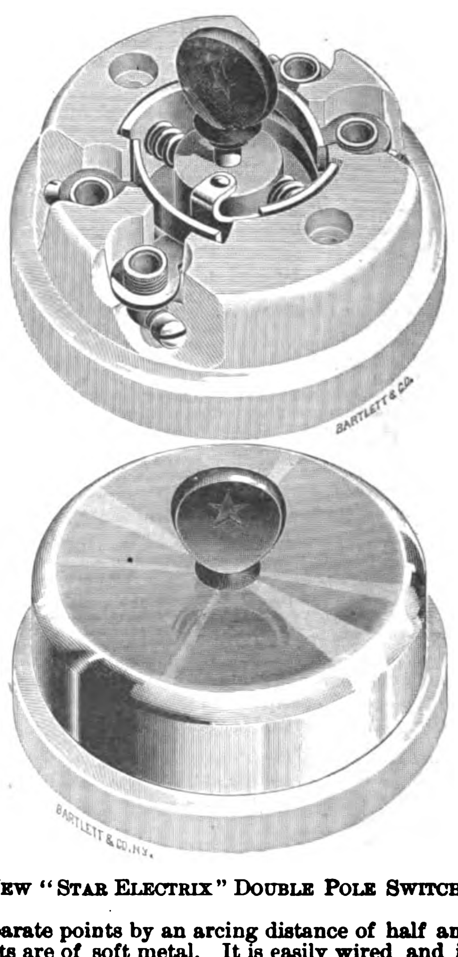
This lamp, a cut of which is shown, differs from others principally in the formation of the carbon filament, the sealing of the filament to the platinum wires, and the exhaustion of the glass bulb. The care that is taken in these three processes, and the attention given to minute details which might have a bearing on the efficiency and life of the lamp, is such as can hardly fail to produce a superior article. In addition the manufacturers pride themselves on the mechanical excellence of their lamp; ill-fitting bases and bulbs, spotted and fire cracked glassware, poor connections, bad sealing and other defects reflecting on the methods of manufacture are entirely absent. Certainly no more symmetrical and well finished lamp has been seen, and the South Boston factory deserves to be congratulated on the result of its labors.

The lamp is at present made in all voltages and to fit all sockets, and in candle-powers ranging from 8 to 50. The manufacture of other sizes may be taken up as soon as shorter nights, and the correspondingly less need of illumination, brings about a possible decrease of orders.

Alexander, Barney & Chapin carry a large stock of the lamps at their New York warerooms, 20 Cortlandt street, and are consequently able to ship from there and from South Boston with equal facility.

NEW STAR ELECTRIX DOUBLE POLE SWITCH.

We illustrate, in the accompanying engravings, a new double-pole switch which is just being brought out by the Star Electrix Co., of Philadelphia. The circuit in this switch is made and broken at four separate points by an arcing distance of half an inch. All the contacts are of soft metal. It is easily wired and is claimed to be the smallest switch of its capacity made.



BARTLETT & CO.
BARTLETT & CO. N.Y.

New "Star Electrix" Double Pole Switch.

NEW YORK INSULATED WIRE CO.

One of the most prosperous and progressive of the wire concerns is that above named, of 649 and 651 Broadway. Its products are well known, widely used, and have secured a most enviable popularity and reputation. So incessant and intense has been the work in connection with the growth of the business that Mr. R. E. Gallaher, the secretary and treasurer, has recently been compelled to seek rest and recreation in the South. He has returned to his labors much the better for the change, ready to give Mr. J. W. Godfrey, the general manager, some relief. Mr. Godfrey will represent the company at the Providence Convention.

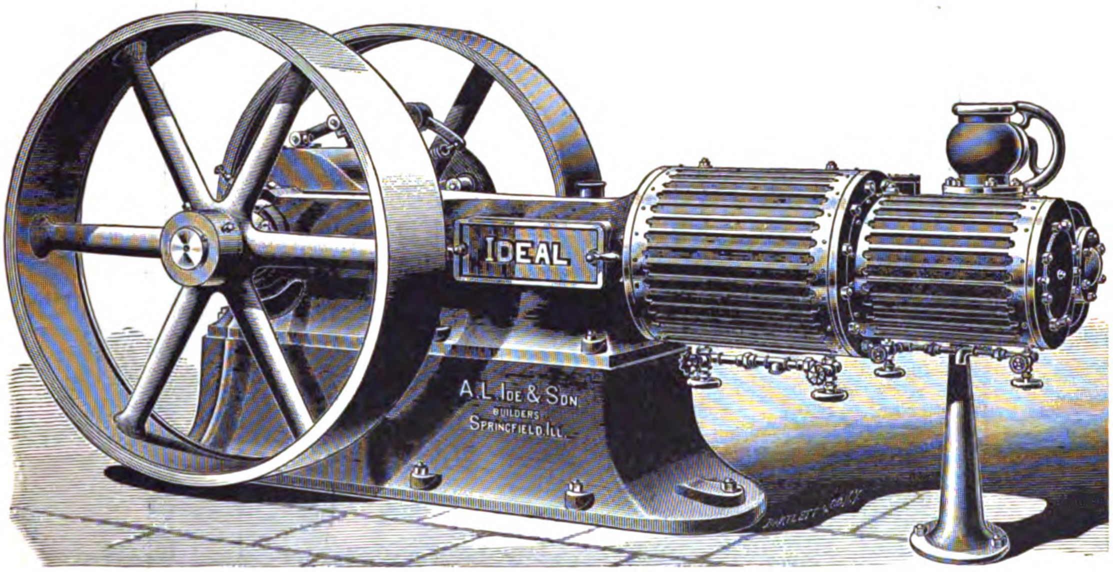
THE "IDEAL" COMPOUND ENGINE.

In designing their tandem compound engine, Messrs. A. L. Ide & Son have endeavored to produce an engine giving the highest economy in the use of steam and meeting all requirements in generating electricity; in short, a reliable, simple engine of great strength and durability. The result of their efforts is, therefore, called the "Ideal" engine, which is shown in the accompanying illustration.

The frame is heavy and self contained, with overhanging wheels, the bearings are all self-oiling, with the working parts enclosed, which reduces the wear, prevents hot bearings and effects a great saving of oil and attendance.

The cylinders are arranged on the well-known tandem plan, and are so proportioned as to give the highest efficiency. The high pressure cylinder is cast on the head of the low pressure, which, in its turn, is bolted directly to the engine bed. By this arrangement the steam has a short, direct passage from one cylinder to the other, without suffering loss of heat, by passing through connecting pipes or receiver. In addition to this advantage, four stuffing boxes are dispensed with, thus reducing the friction and the area of radiating surface. The head between cylinders is cored out, leaving a large space which is filled with non-conducting material, as is also the air space between the cylinders and jackets.

Both valves of this engine are controlled by the governor, they are on the same stem, moving together, and varying in stroke as the load and steam pressure varies, thus giving the advantage of automatic cut-off in both cylinders.



THE "IDEAL" TANDEM COMPOUND ENGINE.

The high pressure cylinder has a piston valve, double ported in order to give larger areas for free admission of steam. The low pressure cylinder has a flat balanced valve, traveling under a cover and supported on hardened steel rollers, and is so arranged that steam is admitted through three ports, giving a quick and wide opening at the beginning of the stroke, in order to reduce the pressure on exhaust end of high pressure piston.

These engines are shipped on heavy iron foundation bases, with driving wheels on, and are ready for immediate use, without the services of an expert, in setting or starting.

QUEEN & CO.

Queen & Co., of Philadelphia, inform us that their exhibit at the Providence meeting of the National Electric Light Association promises to be most interesting. They will show a full line of their special instruments and also a series of their new "Magnetic Vane" ammeters, which are specially intended for central station use. Regarding these ammeters, the Brush Electric Co., of New York, say in a recent letter: "We very cheerfully state that your ammeters as used by us have worked accurately and given most excellent satisfaction."

Queen & Co. have just completed negotiations with Profs. Bristol and Geyer, of Hoboken, N. J., for the control of their patent which covers a new form of recording ammeter. These instruments are not yet perfected, but they promise well, and there is certainly a great demand for a reliable recording meter.

E. G. Willyoung expects to look after the interests of the firm at Providence, and will be much pleased to receive a call from those in attendance and their friends. The exhibit will be in a most prominent position.

MR. W. C. BEHRENS.

With the intention of again devoting his whole time to patent practice, especially in the electrical field, Mr. W. C. Behrens has opened an office at 120 Broadway, where he is prepared to take up patent work and patent causes. He is peculiarly qualified for work of this character, from the fact that he has had quite an active and successful participation in mechanical and electrical manufacturing. It is also a fact not generally known, so fast is the pace in these rushing days, that, as secretary of one of the earliest commissions in the country to investigate the problem of underground wires, his report, presented some seven or eight years ago, is one of the first and most interesting documents on the subject. Mr. Behrens is, in fact, well informed on the electrical art in all its ramifications.

THE EASTERN TELEGRAPH CO., LIMITED.

We have received a copy of the very neat diary for 1891 issued by the above cable company. It is intended primarily for use in England and the Colonies, but abounds in information useful anywhere. At the end of the book are a number of very well executed maps showing the vast reach of the company and its allies in the submarine cable field. The company's headquarters in this city are at 40 Broadway.

J. H. SIEGRIST, JR., & CO.

Messrs. J. H. Siegrist, Jr., & Co, 313 Olive street, St. Louis, Mo., have just furnished the St. Louis Railroad Co. with two "Ideal" engines for the electric light plants in the north and south power houses of that road. They are also erecting "Ideal" engines for the Cox & Gordon Pork Packing Co., and the Illinois Glass Co., Alton, Ill. These engines are self-lubricating throughout, and in place of ten or twelve small oil cups found on most engines, each of which must be carefully watched to keep the oil feeding drop by drop, these engines have but one oil receptacle, from which the oil is automatically delivered in streams to all parts of the engines requiring lubrication. The oil then returns to the oil chamber to be used again. These engines are built in all sizes especially for electric lighting and railway plants.

RAWHIDE PINIONS ON ELECTRIC CRANES.

The following letter has been received by the New Process Rawhide Co., of Syracuse, N. Y.:—

MILWAUKEE, WIS., Jan. 9th, 1891.

Gentlemen: —We have had some of your Rawhide Pinions in use for the past eight months, doing very heavy duty, and find that they show very little wear; while we have used them they have been perfectly satisfactory, and judging from our present experience, we do not know of anything equal to them in situations in which quiet running at high speed is desirable.

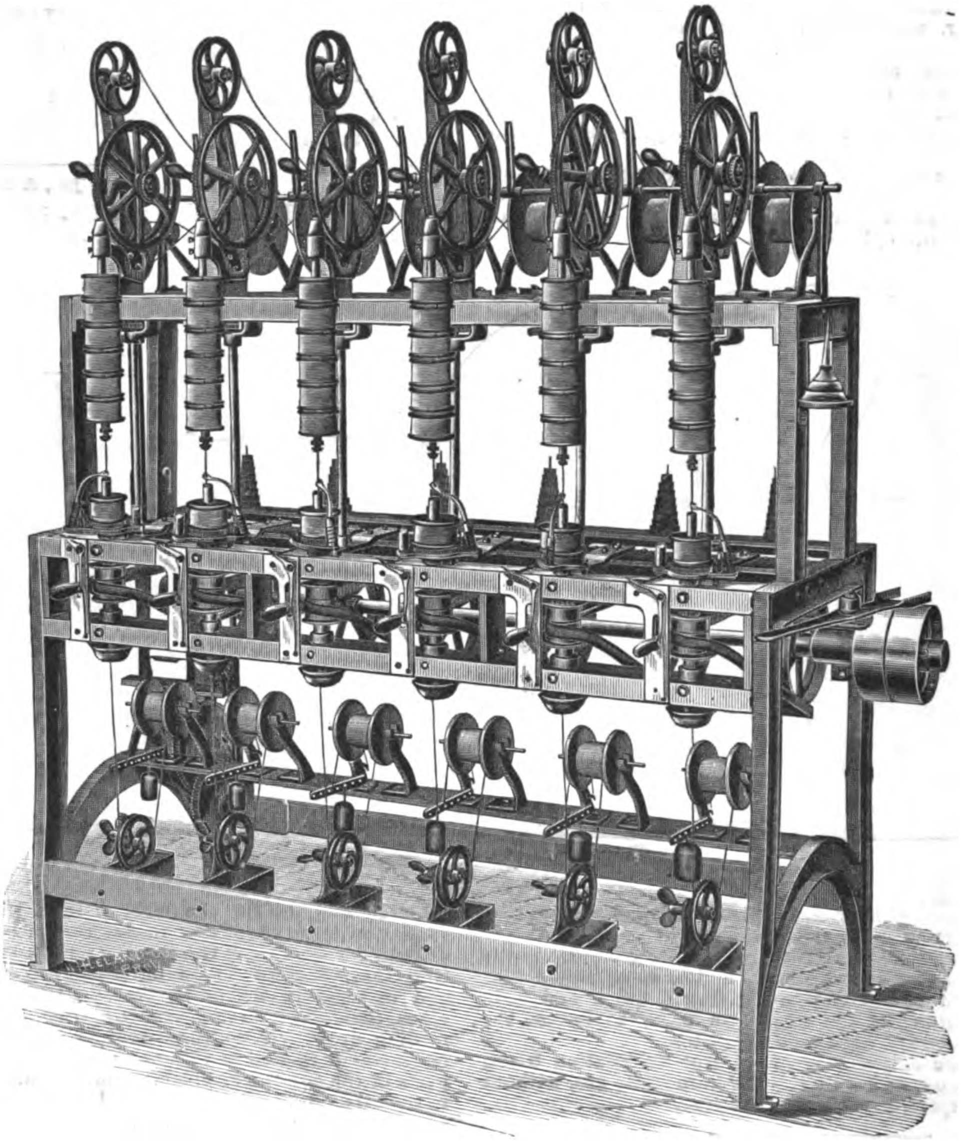
Very truly yours,
[Signed] THE SHAW ELECTRIC CRANE CO.
A. P. SHAW, Supt.

DETROIT, MICH.—The Detroit Electric Power Co. has filed amended articles of incorporation, increasing the number of directors from seven to nine.

A NEW WIRE INSULATING MACHINE.

THE accompanying illustration represents a machine manufactured by the New England Butt Company, of Providence, R. I., for covering the finer numbers of electric wires with silk or cotton, and which embraces some new and ingenious features.

The construction of the machine is such as to secure the maximum speed consistent with perfect work. The winding point has a fine adjustment for tension, and for the different sizes of wires, and the spool being on the spindle admits of high speed. A novel feature is the reserve supply of full spools of silk or cotton, which take the place of those from which the thread has run out, the change being made without cutting the wire. Each spindle is independent, so that different sizes of wires can be wound at the same time, and each has an attachment by which, if a thread breaks or a spool becomes empty, the machine is stopped. A simple and quick arrangement is also provided for changing the speed of the take-up wheel, and for turning back to splice a broken wire. When covered, the wire is wound on a reel at the back, where it is laid smoothly by means of a traverse motion.



THE NEW ENGLAND BUTT CO.'S NEW WIRE INSULATING MACHINE.

This machine has already attracted considerable attention in this country and orders are now being filled for England and Spain.

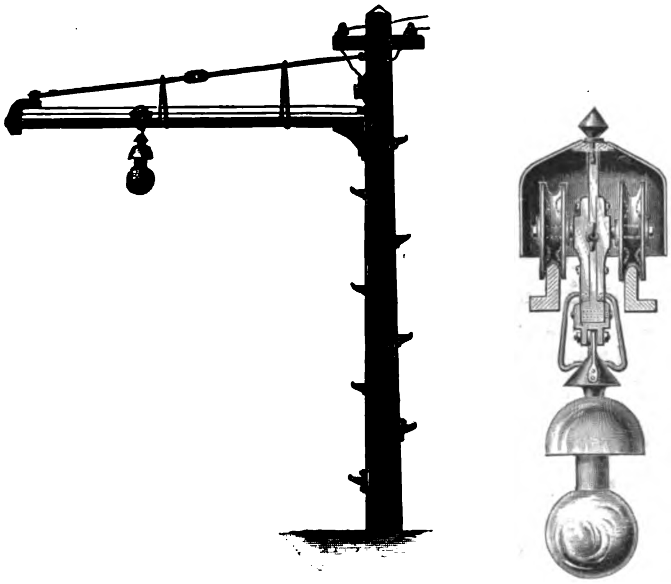
THE ST. LOUIS CAR CO. are building electric cars for Kansas City, Fort Scott, Kan., Waco, Tex., Dallas, Tex., San Antonio, Tex., Springfield, Mo., Memphis, Tenn., Ogden, Utah., Butte City, Montana, Pittsburg, Kan., Lasalle, Ill., The Davenport and Rock Island Consolidated Street Railway; also vestibule cars for Indianapolis, Ind. They are also buildiug 12 snow sweepers, each of which is fitted with three motors, the third motor being used to drive the sweeping device.

THE NATIONAL PIPE BENDING CO.

The National Pipe Bending Co., New Haven, Ct., manufacturers of the National feed-water heater, report a large increase in their business of the last three months over that of the previous year. During this time they have sold one hundred and ninety-four heaters, including:—One 300 h. p. to Washington, Pa.; 200 h.p. to Rosendale, N. Y.; 100 h. p. to Providence, R. I.; 100 h. p. to Middlebury Electric Light Co.; 1,000 h. p. to Lowell Electric Light Co., Lowell, Mass.; 100 h. p. to Denver, Colo.; 500 h. p. to New York City; 200 h.p. to Danbury, Ct.; 150 h. p. to Greenwich, Ct.; 200 h. p. to Elmira, N. Y.; 400 h. p. to St. Johns City Railway Co., St. John, N. B.; 100 h. p. to Aviles, Spain; 500 h. p. to West End Street Railway, Boston, Mass.; 300 h. p. to Wallingford, Ct.; 100 h. p. to Butte, Mont.; 100 h. p. to Jamaica, L. I.; 900 h. p. to Thomson-Houston Electric Light Co., Omaha, Neb.; 200 h. p. Newburyport Electric Light and Power Co., Newburyport, Mass.; 100 h. p. Brooklyn, N. Y.; 150 h. p. to Baltimore, Md.; 500 h. p. to Tyrone, Pa.; 300 h. p. to Brush Electric Light and Power Co., Savannah, Ga.; 50 h. p. to Ghent, Belgium; 200 h. p. to Montreal, Canada; 800 h. p. to East River Electric Light Co., N. Y. City; 100 h. p. to Killingly, Ct.; 150 h. p. to Eastchester Electric Light Co., Mt. Vernon, N. Y.; 200 h. p. to Providence, R. I.; 125 h. p. to Burlington, N. C.; 500 h. p. to South Philadelphia, Pa.; 100 h. p. to Edison Illuminating Co., Hackensack, N. J.; 800 h. p. to Johnson City, Tenn.; 300 h. p. to Morgantown, W. Va.; 300 h. p. to Summerfield Pa.; 300 h. p. to State Line, Pa.; 300 h. p. to Knepper, Pa.; 100 h. p. to New York City; 300 h. p. to Newark, N. J.; 150 h. p. to Marquette, Mich.; 100 h. p. to Indianapolis, Ind.: 150 h. p. to Greenwich, Ct.; 500 h. p. to Edison Illuminating Co., Newport, R. I.; 100 h. p. to Pittsburgh, Pa.; 400 h. p. to Weymouth Electric Light Co., East Weymouth, Mass.; 150 h. p. to Brantford, Ct.; 300 h. p. to Wallingford Ct.; 200 h. p. to Van Ness, N. Y.; 500 h. p. to Memphis Electric Light and Power Co., Memphis, Tenn.; 100 h. p. to Birmingham, Ct.; 125 h. p. to Cambridgeport, Mass.; 150 h. p. to Wilmington, N. C.; 300 h. p. to Terryville, Ct.; 1,200 h. p. to New Bedford, Mass. This company has also placed a large number of small heaters in isolated plants, particularly in manufactories and large buildings.

ELECTRIC LIGHTING SPECIALTIES OF E. M. CARHART & CO.

A number of inventions and improvements for electric lighting purposes have recently been devised by Mr. Van A. Thomas, superintendent of the Narragansett Electric Lighting Co., of Providence, R. I., some of which we illustrate in the accompanying drawings, as manufactured by E. M. Carhart & Co., of Providence, R. I.



FIGS. 1 AND 2.—MAST ARM.

The mast arm, shown in Fig. 1, is simple, strong and durable, made of two pieces of L iron, which are used as conductors as well as for the track to carry the lamp out over the street. These tracks with the supporting brace, are insulated from the pole, dispensing with the cable, which has always been a source of annoyance, as well as incurring continual expense. A switch is placed on the pole to switch out the lamp circuit while the lamp is being trimmed. Fig. 2 shows a section of the arm.

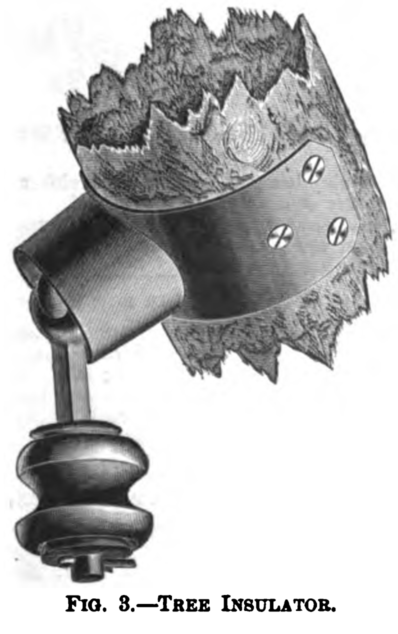


FIG. 3.—TREE INSULATOR.

By the use of the tree insulator, shown in Fig. 3, the line is kept in a normal position, while the tree is allowed to sway in the wind, thus relieving the wire of all strain.

The carbon holder, shown in Fig. 4, is claimed to be an improvement over any other in use. When the thumb screw is turned to take out the carbon, it holds the adjustable part of the holder open ready to receive the new carbon. The operation will be readily understood by reference to the illustration.

The arc lamp insulation, Fig. 5, is intended for use upon lamps that are necessarily hung so low as to admit of being accidentally touched. It is made to fit any style of lamp.

The detachable pole step for trimmers, shown in Fig. 6, does away with the necessity of the trimmer carrying a ladder, in addition to his load of carbons. A socket is fastened to each side of the pole, and the trimmer, taking two small steps, places one in each of the sockets, goes up the pole, trims the lamp, comes down, takes out his steps, replaces them in his pocket, and goes to the next lamp post, and so on, thus accomplishing a greater amount of work.

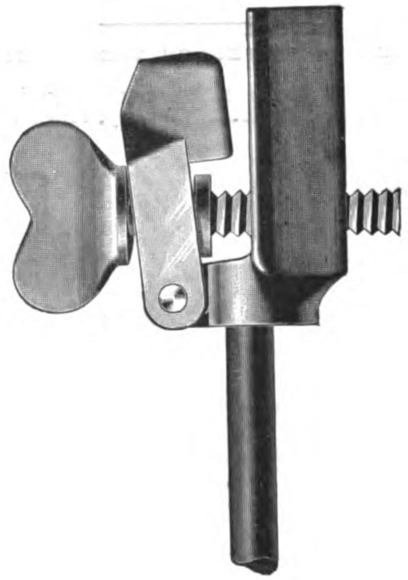

FIG. 4.—CARBON HOLDER.

The cable clip, Fig. 7, is simple in construction, easily adjusted in passing a fixture, and very durable, being made of the best galvanized iron. (For Figs. 6 and 7, see page 212.)

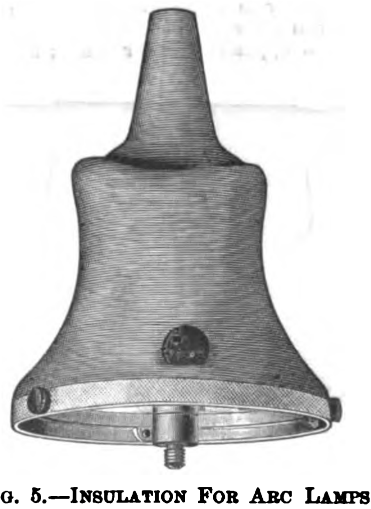

FIG. 5.—INSULATION FOR ARC LAMPS.

PAGE BELTING CO.

The above standard belting house has lately opened a fine New York store at 16 Dey street, right in the heart of the electrical district, and there is carrying a remarkably complete and well selected stock of belting, lace leather, cut lacings, etc. As is well known, the company make a specialty of belting for electrical purposes, and are celebrated for the dynamo double belts, "Eureka" dynamo belt, "Crown" extra short lap oak belt and "Acme" leather link belt. Mr. George A. Pierce is manager of the New York branch and invites electrical people to call and inspect the company's goods.

AMERICAN ELECTRICAL WORKS.

In connection with the meeting of the N. E. L. A. in Providence this week President Eugene Phillips, of the American Electrical Works, announces the intention of that concern to celebrate the opening of its new factory by an entertainment or reception there on Thursday evening, February 19. Mr. Phillips is not in the habit of inviting people freely into his factories, but on this occasion the rule will be broken and the place will be the scene of unlimited hospitality. Those who are familiar with the summer festivities of the Works are a little curious to see how a clambake, under the same auspices, will go in winter, but we know that they will be able to say of Mr. Phillips what Florizel said of Perdita: "What you do, still betters what is done."

CLEVERLY'S PERFECTION THERMOMETER.

Not satisfied with the sensation created by his blotting pads and artistic calendars, Mr. H. A. Cleverly, 1018 Chestnut street, Philadelphia, has brought out a new combined electric light molding and shingle, on which he has placed a "perfection" thermometer. In order to indicate the warmth of his feelings towards a customer in whose pocket lurks a big order, Mr. Cleverly has placed one arrow opposite "Fever heat"; and in order to illustrate his sentiments towards advertising canvassers, he has placed another arrow 30 degrees below zero. At the back of the shingle are instructions as to what should be done in case the "column of red liquid" gets broken up, the remedy being "one or two swift downward swings, stopping with a sudden jerk, almost in the same manner that you would wield an axe in chopping wood." It happens, however, that the column in the Cleverly thermometer contains a *purple* liquid, and, as everybody knows, the calisthenic exercises with a purple column are quite different. This is only another of Cleverly's deeply-planned Philadelphian jokes.

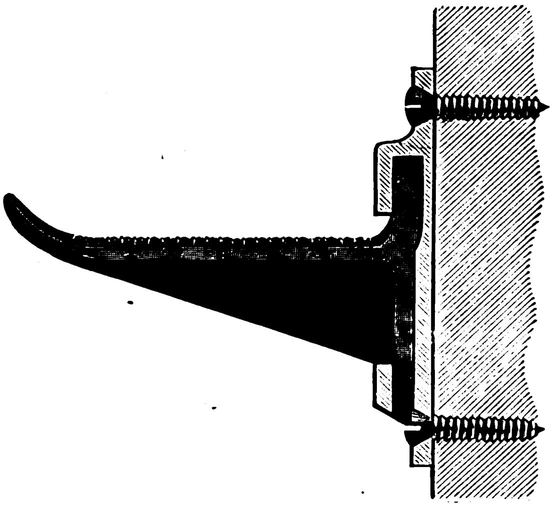

FIG. 6.—ADJUSTABLE POLE STEP. (*See page* 211.)

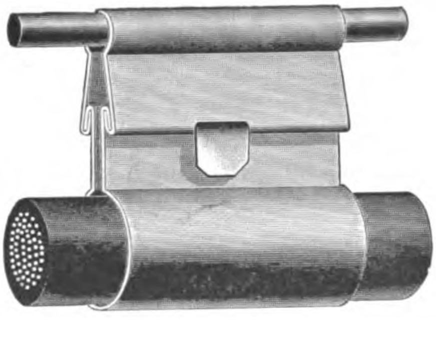

FIG. 7.—CABLE CLIP. (*See page* 211.)

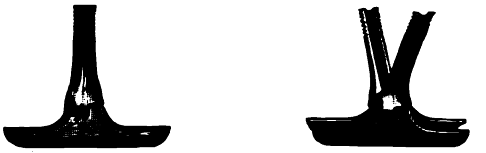
THE SOUTHERN ELECTRICAL SUPPLY CO., 823 Locust street, St. Louis, who make a specialty of Okonite wires and cables, had a most prosperous year's business. They have lately taken the agency for the Connecticut motor, and have made a number of sales.

ERNST ELECTRIC STORAGE COMPANY.

This company has been organized to manufacture the Ernst storage battery described in our issue of February 11th. The patents of Mr. V. H. Ernst cover a variety of improvements in storage batteries, and it is expected that cells will soon be ready for the market. The officers of the company are Thomas Grimwood, president; Joseph Thomson, vice-president, and Smith S. Frambes, secretary and treasurer. The offices of the company are at 115 Broadway, this city.

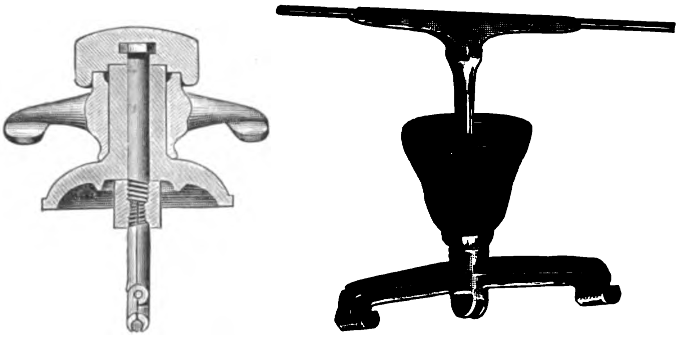
A NOVEL TROLLEY WIRE CLAMP.

ONE of the most important features in the installation of an electric road is the proper construction of the appliances for connecting the span and trolley wires. Objections have been made to the present means of holding the trolley wire, for the reason that it has been necessary in most cases either to solder the connections, which necessarily weakens the wire, or else to hammer together the sides of the clamp, which causes trouble and delay in adjusting the position of the insulator.



FIGS. 1 AND 2.—THE BREWSTER TROLLEY WIRE CLAMP.

The accompanying illustrations show the "Brewster clamp," made by the Electric Merchandise Co., of 11 Adams street, Chicago. Figs. 1 and 2 show the clamp, which is made of two sections of hard and tough brass rivetted together with a steel pin. After the clamp has been placed upon the trolley wire and closed, the insulator is screwed down upon it, firmly holding the wire without soldering or hammering, and presenting a perfectly smooth surface to the trolley. Figs. 3 and 4 show the clamp attached to the standard trolley wire insulators, but the clamp can be used on any trolley hanger, and is sold either separate or in connection with any other style of insulator.



FIGS. 3 AND 4.—THE BREWSTER TROLLEY WIRE CLAMP.

Mr. Mason, the general manager of the company, will be at the Providence convention, with this and many other specialties.

ROOT WATER TUBE BOILERS.

A large number of Root new water tube steam boilers are in use in electric light and power stations. The manufacturers, the Abendroth & Root Manufacturing Co., 28 Cliff street, New York, are very busy and find the demand for their specialty steadily growing greater and more general. They have shipped a large number of their boilers to Cuba recently.

NEW YORK BELTING & PACKING CO.

All kinds of vulcanized rubber goods of the best quality for mechanical purposes can be found at the warerooms of the New York Belting & Packing Co., 15 Park Row, New York. The goods made by this concern can be found in every civilized portion of the world, and are famous for their durability and fine workmanship.

OKONITE.

Messrs. Candee, Manson, Cheever and McCoubray will be at the convention in the interests of the International Okonite Company, Limited, New York and London. Okonite insulated wires and cables have attained an enviable degree of popularity, and keep on going higher in public favor day by day.

THE INTERNATIONAL OKONITE COMPANY, LIMITED.

In a recent issue, The Electrical Engineer had occasion to describe the offices of the International Okonite Company, at 13 Park Row, New York.

The leading lights of the New York end of this company are the gentlemen whose portraits are here given. Captain Willard L. Candee was born in the year 1851, at Yonkers, Westchester County, N. Y., whence he subsequently removed to Brooklyn, N. Y. He is well known socially in that city, where he holds the captaincy of Company B, in the crack 23rd regiment. He has been connected with the International Okonite Company since its start, and to his efforts is due largely the proud position occupied by this concern among American manufacturers to-day

Willard L. Candee.

Mr. H. Durant Cheever, who, with Mr. Candee, conducts the business management of the company in America, was born in New York city 25 years ago. Mr. Cheever is a graduate of Harvard and became associated with the company in July, 1888, directly after completing his course at College. He is a thorough business man, bright and progressive, and has no doubt a prominent business career before him.

H. Durant Cheever.

Mr. George T. Manson is probably one of the best known men in the electrical field. He is a native of Massachusetts and 40 years of age, and has been connected five years with the International Okonite Company, where he co-operates with Messrs. Candee and Cheever in the business management of the concern. Mr. Manson was previously interested for many years in the New England Telephone and Telegraph Company, of Boston, Mass. His whole-souled, genial nature has won for him a host of friends.

Mr. F. Cazenove Jones, general manager of the company's factories, at Passaic, N. J., was born in Maryland 35 years ago, and is a descendant of Captain John Paul Jones, whose bold manœuvres embarrassed English commerce so much during the Revolution. Mr. Jones has been connected with the International Okonite Company for many years, and his thorough knowledge of mechanics, and long experience with the New York Belting and Packing Company—he having for a long time had charge of the manufacturing departments of this concern at Passaic, N. J., and Newtown, Conn.—fit him specially for the important position he occupies.

George T. Manson.

F. Cazenove Jones.

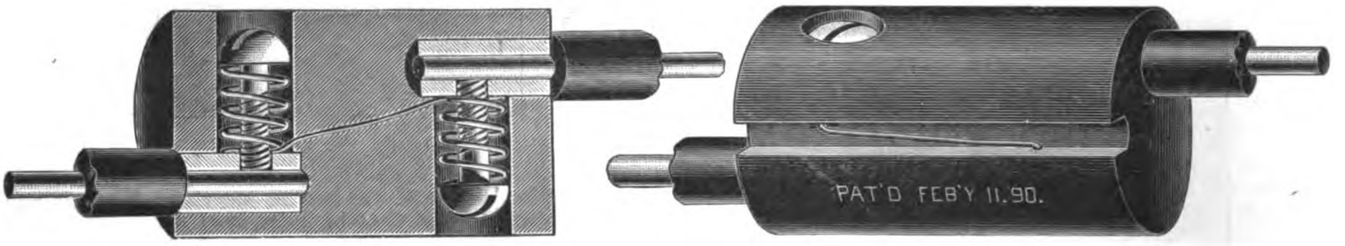
MR. BENJAMIN R. WESTERN.

Few manufacturers have the time and inclination to attend to the exacting details of profitable advertising. It is a business in itself and requires one's undivided time and attention. Those who want to be well served in this regard, should employ the services of an expert skilled in such matters. Mr. Benjamin R. Western, proprietor of the Manufacturers' Advertising Bureau and Press Agency, 111 Liberty street, New York, is amply able to fill the bill, and will be at the convention with an inexhaustible fund of shrewd and invaluable information regarding advertising. Mr. Western ought to write a book on "Successful Advertising."

A NOVEL THERMAL CUT-OUT.

THE accompanying illustrations show the novel thermal cut-out manufactured by the Electrical Specialty Company, Nos. 18 and 20 Cortlandt street, this city. The illustrations, Figs. 1 and 2, are three times the actual size of the device, one showing the cut-out in use, the other the interior arrangement of it. It will be noticed that this safety catch for electric circuits consists of a cylindrical block of hard rubber having only two binding screws for the line conductor, one at each end, and on opposite sides. The block is provided with an external groove on one side for the fuse wire leading from one binding screw to the other. A short spiral spring is inserted under the head of each screw and binds directly upon the fuse wire, thus ensuring a perfect contact, no matter how far the binding screw penetrates in the opening.

The cylindrical block in each end of the cut-out into which the conductors are inserted and through which the binding screw passes, makes a perfect contact all around the wire, instead of a contact met by the end of the binding screw and merely resting on the fuse wire. The cut-out is designed for use in almost any place where a safety catch is needed, but is of especial value where but a small space is available, such as in electroliers and brackets where it has been necessary heretofore to make large and unsightly canopies or cut-shaped shields to cover the safety catches required. No tape is required to insulate this fuse block as all metallic parts are countersunk in the hard rubber. The simplicity of construction renders it an easy matter to replace a burnt-out fuse wire without danger of burning the fingers. This cut-out will be of value in interior conduit work. The fuses can be easily renewed but the user will save time by putting on a new cut-out and renewing the fuse in the old one at his leisure. The company propose to manufacture this novelty for all sizes but at present it is made only for from one to three lights.



FIGS. 1 AND 2—A NOVEL THERMAL CUT-OUT.

SOME RECENT FORT WAYNE PLANTS.

The following business has been done by Mr. Thomas Cooper, special agent for the Fort Wayne Electric Co., and Mr. W. J. Morrison, from the Buffalo office, during the past six weeks: City of Jamestown, N. Y., 150 arc lights; Batavia, N Y., 120 arc lights; Warsaw, N. Y., 60 arc lights, 750 alternating; Niagara Falls, Ont., 60 arc lights; U. S. Elec. Light & Power Co., Buffalo, 80 arc lights. Not too "frosty" a trade for six weeks.

THE NEW PARTRICK & CARTER HEADQUARTERS.

Partrick & Carter Co., of Philadelphia, who have been established since 1867, report trade as being very good for this season, and they look forward to a busy year for those engaged in electrical pursuits.

Their new establishment at No. 125 South Second street, and No. 131 Gothic street is now in perfect running order, and they have one of the best appointed and most attractive electrical supply houses to be found anywhere. Their store and show room is 120 feet in length by 20 feet in width, and is fitted up in the most approved manner for the display and storage of their stock of which they carry a large line.

A distinguishing feature of the store is the lettering of all drawers, cupboards and bins so that he who runs (or walks) about 120 feet away may read the names of the million and two articles which go to make up the stock of a fully equipped electrical supply house.

The counting-rooms and private offices are located on the first floor of No. 125 South Second street, and the packing and shipping department is in a wing 50 feet by 20 feet running through to Gothic street. The buildings are five stories in height, and are occupied exclusively by Partrick & Carter Co., the upper floors being devoted to the factory of the firm, who own and operate the steam power and heating plant together with an electric lighting system. Their factory has always been a well equipped one, and since becoming located in their new buildings they have added largely to their facilities by additional machinery and force. They are now making up their specialties of patent needle annunciators, bells, batteries, etc., together with their regular lines in larger quantities than ever before. Their 1891 catalogue is now in the hands of the printer, and will come from the press shortly. Its issue has been delayed on account of their removal and other changes. The catalogue will be the most complete ever published by this old established firm, and a copy should be in the hands of all who buy electrical supplies.

THE "ELGIN" TELEPHONES.

The Elgin Telephone & Electrical Supply Co., of Elgin, Ill., report that their acoustic or mechanical telephones are becoming popular in foreign countries, not less than in the United States. They have lately received orders from Stockholm, Sweden; Preston, England; and Moscow, Russia, as well as other foreign places. They have lately added an attachment in the shape of a mechanical bell which they claim rings as well as an electrical vibrating bell, and which they put in when a bell call is desired.

CORNELL ELECTRICAL ENGINEERING CO.

THIS concern which has just opened an office at 45 Broadway, this city, is composed of thorough business men who have also had practical experience with the details of electric railway lighting and power work. They will do a general business as consulting and constructing engineers, but will devote themselves particularly to the equipping of electric railways.

The company depends for success on the very fact which causes uneasiness in so many quarters, viz:—that purchasers of electric plants have learned to insist upon the best possible work at moderate prices. Every detail of their work will be done under the charge of skilled men, a number of whom have been actively employed by them for the past year, and the placing of a contract in the hands of the company will insure excellent work in every particular.

The company has just finished the electrical equipment of the Hamilton & Lindenwald Electric Railway, at Hamilton, Ohio, which is of the most substantial character throughout. The station equipment is the finest.

MR. GEORGE WORTHINGTON.

It is with much regret that we record the serious indisposition of Mr. George Worthington, the popular publisher of *The Electrical Review*. He will be unable to attend the National Electrical Light Convention at Providence this week, and is now with friends in Buffalo. His illness is the more unfortunate from the fact that he had been invited to take a prominent part in the decennial exercises, in recognition of the good work done by himself and colleagues at the time of the foundation of the Association. We venture to extend our sympathies both to himself and to his editorial associate, Mr. C. W. Price, at this juncture, knowing that in so doing we but voice also the sentiments of innumerable friends.

A. & W. S. CARR CO.

A. & W. S. Carr Company, of 138-140 Centre street, New York, offer some good bargains in iron pipe, valves and gates, and will quote attractive prices on iron and brass castings. Their shops and foundry at Paterson, N. J., are doing an excellent business.

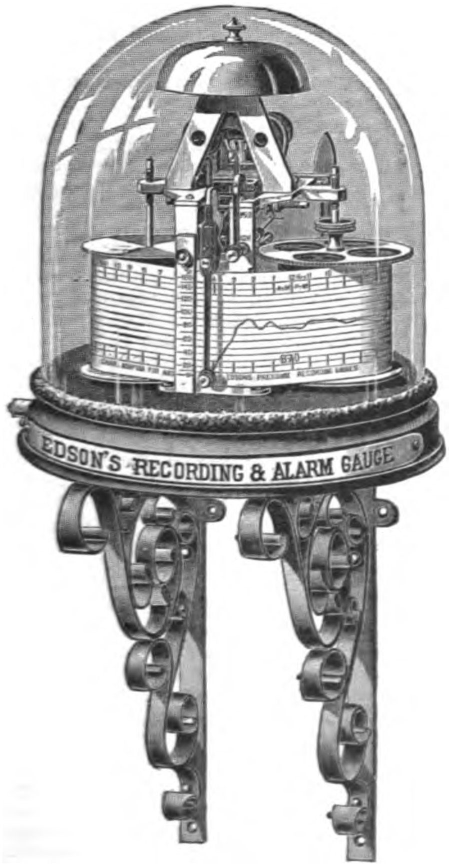
FISHKILL-CORLISS ENGINES.

The improved Fishkill-Corliss horizontal engines are especially well adapted for electric lighting plants. The best materials only are used in their construction, resulting in great durability; while the "cut-off" device used, insures what is believed to be the most economical use of fuel yet accomplished. Write the Fishkill Landing Machine Company, Fishkill-on-the-Hudson, N. Y., for a new catalogue. It is of great interest.

THE CENTRAL THOMSON-HOUSTON CO., through their agent, Mr. Alex Lewis, have just closed a contract for 6 motors with the Marion Street Railway Co., of Marion, O.

EDSON'S NEW STEAM PRESSURE-RECORDING GAUGE.

UNIFORM steam pressure is so important in operating electrical plants that some device which will enforce increased care on the part of the fireman is indispensable. Mr. Jarvis B. Edson, of 87 Liberty street, New York, who, in connection with his engineering business, has long been known for his persistency in urging the advantages of uniform steam, and the inevitable economy resulting from careful firing, has recently introduced some improvements in the construction of his well-known pressure-recorders, which we illustrate by the accompanying illustration of his style No. 1. As will be noticed, he has dispensed with the indicating hand and dial, relying upon the vertical scale solely, and in place of the hand and dial, has introduced an electric bell, current for which is conveyed through the two binding posts shown at the side of the base. This electric bell is operated by an adjustable circuit closer, shown near the vertical scale, and enables an alarm to be sounded either on the instrument, or at a distant point, when any limit of pressure at which the circuit closes has been set is reached. The modification of the arrangement provides a low circuit closer, in addition to the above, operated from the same battery, so that while the recording chart below in recording continuously the pressure carried, acts as a constant check, or reminder upon the man in the fire-room, the electric bell device undertakes to call attention to the dereliction, and enables an immediate remedy; whereas, without the alarm, the pressure might be either above or below normal for a considerable period without being noticed. The mechanical construction of this new style of instrument is a vast improvement over the older one, inasmuch as lost motion and wear is provided against, and its simplicity has admitted of a reduction in price. This style is provided with metallic paper ruled to the particular travel of the diaphragm, and spaced off in hours and half hours. The marking lead has been dispensed with and silver wire substituted, the whole being surmounted upon an ornamental black iron bracket. Any steam plant must be intelligently conducted in order to be economically maintained. The manifold duties of the superintending engineer, or manager, make it important that he should be provided with some means of knowing how the steam is carried during his absence. Neglected or overfed fires are ruinous to perfect combustion, without which fuel economy is lacking, and as absence of full information invites carelessness, encourages indifference, and, and in fact, paves the way for perpetual waste and final accident with "nobody to blame," a good pressure recording guage can not be too highly recommended.



EDSON'S NEW STEAM PRESSURE RECORDING GAUGE.

THE TAYLOR PRIMARY BATTERY.

THE demand for a powerful primary battery cell is so large that it is well worth the while of inventors to effect improvements in this class of electric generators. Among those who have attacked the problem in a successful manner is Mr. T. F. Taylor, who has invented a form of battery which embodies several new features. In this cell zinc is entirely immersed below the surface of the liquid so that there is no metal wasted as in the forms usually employed, it being suspended by a light frame which is unattacked by the liquid. The porous cups are made of special material and the contact of the multiple carbon is effected in such a manner that no corrosion takes place on the junctions. The liquid employed in the outer jar is a 6 per cent. sulphuric acid; that employed in the porous cup for depolarizing is intended to replace nitric acid with all its attendant inconveniences. The material for its composition is in the form of a powder, which can be readily shipped and solution prepared at the place where the battery is used. One remarkable feature of the cell is its very low internal resistance, which in the No. 1 cell, which measures 12x7 inches, is only .08 ohm. The electromotive force of the cell is 2 volts, so that such a cell on short circuit will give 25 amperes, which can be maintained almost indefinitely during the life of the solution. Three of these cells will keep a 3 c. p. lamp brilliantly lighted for 160 hours, and will run an eighth h. p. motor. The No. 2 cell, 8x5½ inches, will give a current of 8 amperes on short circuit, and the amateur battery, 3x8½ inches, will maintain a small Edison lamp for several hours. This cell, which has attracted considerable attention, is manufactured by Messrs. Taylor & Son, of 39 Dey street, New York.

Comparing this cell, with its very low internal resistance and high E. M. F., with the ordinary sized gravity cell, it will be evident that for local work one cell of the former replaces from 10 to 15 of the latter.

AN IMPORTANT WENSTROM ELECTRIC RAILWAY CONTRACT.

Messrs. Chadbourne, Hazelton & Co., of Philadelphia, general agents of the Wenstrom Consolidated Dynamo and Motor Co., of Baltimore, have just closed a contract with the Denver, Lakewood and Golden Railway Co., of Denver, Colorado, for an extensive electric railway. This road runs from the heart of Denver directly across the country to the city of Golden, a distance of 14 miles, passing through several smaller towns on the way. The grading on this road is completed, and the work of laying the rails is about to commence. Sixty pound T rail will be used. This road is the only direct communication between these two cities, and Mr. Starkweather, vice-president and general manager of the road, claims that the freight business alone on this line will pay a 10 per cent. dividend on the investment.

The equipment at first will consist of two 100 h. p. motor cars, designed by Mr. Leonard Atwood, the mechanical expert employed by Messrs. Chadbourne, Hazelton & Co. These motor cars will be fitted with special Wenstrom slow speed direct geared motors, designed by Mr. H. F. Parshall, on the same general lines as the regular Wenstrom-Parshall slow speed street car motor. These are guaranteed to run 25 or 30 miles an hour, and haul loaded freight cars.

For the passenger traffic, long 6-wheel cars with pivotal trucks will be used. These cars will be handsomely fitted up, and have a seating capacity for about 40 people. Two standard Wenstrom slow speed, direct geared motors, 30 h. p. each, will be put on these cars. They are calculated to run 15 or 20 miles an hour, hauling two other trail cars.

The power plant will be divided into two sections; one station being in Golden, the other near Denver. Each one will be fitted up with four 80,000 watt Wenstrom street car generators of the newest and most approved design, together with the necessary steam plant to operate them. No money will be spared to make this road complete in every detail.

Chadbourne, Hazelton & Co. have had their expert, Mr. Atwood, in Denver for some weeks going carefully over this work, and laying out necessary plans for the successful equipment of the entire line. It is intended to have the road open for traffic as near the first of May as possible. They expect to increase this equipment very materially during the summer, as the traffic over this line will undoubtedly be very great.

FRANKLIN LEONARD POPE.

Mr. Franklin Leonard Pope, who was for a time in the special service of the Westinghouse Electric and Manufacturing Co., has resumed his practice as consulting electrician, expert, and general assistant to counsel in technical and patent litigation. His offices are in the new Wilks building, 15 Wall street, New York.

WESTON ELECTRICAL INSTRUMENT CO.

Advices from the Weston Electrical Instrument Company, Newark, N. J., indicate a growing demand for the company's standard portable direct-reading voltmeters and ammeters. The company has been exceedingly busy of late, and the outlook for the ensuing year is very promising.

A NOVEL THERMAL CUT-OUT.

THE accompanying illustrations show the novel thermal cut-out manufactured by the Electrical Specialty Company, [illegible] and 20 Cortlandt street, this city. The illustrations [illegible] are three times the actual size of the device, one showing the cut-out in use, the other the interior arrangement of [illegible] noticed that this safety catch for electric circuits [illegible] of a cylindrical block of hard rubber having [illegible] screws for the line conductor, [illegible] sides. The block is provided with [illegible] for the fuse wire leading from [illegible] short spiral spring is inserted [illegible] binds directly upon the fuse [illegible] no matter how far the [illegible]

The cylindrical block [illegible] conductors are inserted [illegible] passes, makes a perfect [illegible] contact [illegible] on the fuse [illegible] place, where [illegible] supplies [illegible] of 150 [illegible] an ex- [illegible] a num- [illegible] and their [illegible] they have [illegible]

[illegible]

The Crocker-Wheeler [illegible] Company has secured as [illegible] whose long and successful [illegible] Railway and Motor Company [illegible] sufficient guarantee that the [illegible] will be found at the head of the procession.

[illegible] ELECTRIC RAILWAY SYSTEM.

The Detroit [illegible] Works are reported by Mr. C. A. [illegible] manager, to be busier than ever, filling [illegible] railway equipments. They have sold during [illegible] outfits, namely, two for the Richmond [illegible] Railway, of Richmond, Va., and two for the [illegible] Railway Co. Both these are equipped already with [illegible] make. Mr. W. A. Stadelman, the company's Philadelphia agent, secured these contracts.

NEW YORK GOSSIP.

WM. E. DAVIS, late of the engineering department of the Edison Company, is now superintendent of the Toronto Incandescent Electric Light Company and has located there permanently.

THE INDIA RUBBER & GUTTA-PERCHA INSULATING WIRE COMPANY have removed their offices to 315 Madison avenue, corner of 42d street, and are comfortably installed in their new quarters and ready to meet their old friends at the above address.

WESTERN TRADE NOTES.

MR. EDWARD R. GRIER, brother of Thos. G. Grier, engineer of the National Engineering Bureau, and well-known in electrical circles in the West, has been appointed superintendent of the Southern Electric Company, of Philadelphia, Pa. He was formerly associated with the North American Construction Co., which well-known concern was evolved from the old Marr Construction Co. Mr. E. R. Grier was one of the experts on the Hoosic Tunnel installation of the Westinghouse system, which was one of the notable plants of the country when put in, and he invented the joint used on the lead covered cables employed in carrying out that work. He was also electrical expert on the private residence plant of George Westinghouse.

MR. GEORGE CUTTER, the "Electrical Specialist" of the West, will once more handle the famous "Simplex" wires and cables. He will carry a large and extensive stock of all sizes in the Rookery, where he has secured ample space in the basement for the purpose; and all orders will receive that prompt attention and despatch for which Mr. Cutter is noted.

MR. J. S. SPRUANCE, of the Star Electrix Co., of Philadelphia, Pa., was a recent welcome visitor to Chicago. He visited on his trip Minneapolis, St. Paul, and other Western cities and found Star Electrix specialties in demand everywhere.

MR. G. A. EDWARD KOHLER, the representative of the Eddy Motor Co., of Manchester, Conn., reports the following sales of motors during the past month: Five 2 h. p.; one 3 h. p.; three 5 h. p.; one 7½ h. p., and two 10 h. p. machines, making an aggregate of 55½ h. p. This record shows how rapidly these motors, which embody such excellent mechanical, electrical and scientific principles in construction, are finding wide employment and favor in the West.

THE [illegible] ELECTRIC MATERIAL COMPANY, Rooker [illegible] have brought out a new catalogue which is actual [illegible] unique in its line. The printing in color and typo [illegible] unique, the arrangement of the many standard articl [illegible] specialties which they handle is also unique, and lastly, t [illegible] of the book which presents the two pages to the read [illegible] it being read from top to bottom, down both sheets, [illegible]. It reflects the greatest credit on Mr. Ernest Hoefer, t general manager of the company, who got it up, as being som thing of a decidedly handy size and novel form and is especial adapted to being found in the pockets of the purchasers of ele tric light power or railway supplies, from which it will also dra the weighty silver dollars in exchange for the enticing goods di played in its pages. Truly it is a pleasant thing to see a real novel catalogue.

MR. D. B. DEAN, so long and favorably known as the energet and versatile Western representative of the *Electrical Review* New York, has resigned his position with our esteemed conte porary, and has accepted a position as traveling representative the Electric Merchandise Co., of this city. His wide acquaintan and pushing qualities peculiarly fit him for his new sphere work. He will find himself in congenial companionship with M W. R. Mason, the manager of the Electric Merchandise Co., a Mr. Dean will make a highly active and efficient representative that well known concern.

MR. H. JENKINS, who until recently has been associated wi the National Engineering Bureau, has now connected hims with the Pond Engineering Co. and will shortly proceed Omaha, where he will take charge of their office. Mr. Jenkins a hard worker, full of energy, and push and will make his ma in the engineering business in Nebraska and neighboring ter tory.

THE CHICAGO RAWHIDE MANUFACTURING CO., 75 and 77 O street, Chicago, are meeting with great success with the Mal hydraulic rawhide packing, which they manufacture. This pa ing has many marked advantages particularly in wearing qu ties, and is easily compressed, being a soft packing, thereby co pensating for its slight wear. It will not cut a rod, plunger cylinder, on account of the method of curing the rawhide, wh causes it to act as a lubricant and effect a notable saving in pow It is adapted for all purposes where a cool water packing employed for freezing, hydraulic machines and the like.

MR. CROLIUS, of the Globe Light and Heat Co., Michigan str Chicago, is very busy extending the electrical specialty dep ment of the company. They will bring out a number of n designs in fixtures and so forth for electrical work, and are do a brisk and increasing business.

NEW ENGLAND TRADE NOTES.

CLAFLIN AND KIMBALL have opened an office at 116 Bedf street, Boston, and will hereafter act as general agents for Perkins Electric Lamp Company, of Manchester, Conn., and conduct the entire selling department of that company. All c respondence should be directed to them regarding sale or p chase of Perkins incandescent lamps, when it will receive same prompt attention as heretofore.

MR. W. C. FISH, who has recently returned from a th years' trip to the other side of the water, where he has been i mately connected with electrical enterprise, has recently beco associated with Mr. H. B. Cram in the management of the Be stein Electric Company, of Boston. Mr. Fish's wide experie and accurate knowledge of the wants of the electrical fratern should make him a valuable acquisition to the Bernst Company.

THE BUCKEYE ELECTRIC COMPANY, of Cleveland, O., h opened a New England office, at 85 Water street, Boston, w Mr. Louis R. Wallis as resident New England agent. Mr. Wa is well acquainted with the incandescent lamp business, hav been for several years connected with the Bernstein Electric and he already reports a large demand for the Buckeye lamp.

THE GOULD AND WATSON COMPANY, the well-known dealer mica, and manufacturers of moulded mica insulators, h opened a branch office at 170 Washington street, Chicago, un the management of Mr. R. B. Pierpont, who has been connec with them for some years in Boston. The demand for moul mica still grows, and it has now got to be regarded, from the of experience, as one of the very best insulators known.

THE SHIPMAN ENGINE COMPANY, of 200 Summer street, Bost have recently shipped one of their four horse power automatic gines to Don Carlos Pacheco, Vera Cruz, Mexico, for driving a sn electric dynamo, and a two anda four horse power engine to Ho lulu also for electrical purposes. The Shipman automatic eng uses kerosene for fuel, and is made with boiler and engine c plete. They are made in sizes of from one to eight horse power, and are simple, durable and efficient. They are admirably adapted for running small electric plants, requiring no skilled care, and making no dirt or dust.

$$\frac{\quad}{r+g}\int$$

Now $i = \dfrac{E}{2R+r+g}$, and therefore,

The determination can be carried out equally well with a *differential inductor* and an ordinary single coiled galva-

---

1. If we take account of the mutual and self-induction in the rest of the circuit, we arrive eventually at the formula given here.

F. P. LITTLE & CO.

This concern, of 141 East Seneca street, Buffalo, are in the field as contracting and consulting electrical engineers. They handle the National Electric alternating system, the Eddy motors and the Mather plating dynamos, and they are prepared to take contracts for electric street railroads, isolated electric light plants, long-distance transmission of light and power, etc. They also keep all kinds of electrical supplies in stock, and are the Western New York agents for the Electrical Supply Co., of Ansonia, Conn. The concern is in good shape to attend promptly and efficiently to all the business coming to it, and starts under its new auspices with the good wishes of a very large circle of friends and of an equally large clientage in the various branches of the electrical industry.

EMMET BROS. & GRISWOLD.

A handsome new Spring catalogue of electric railway supplies has just been issued by this young and active concern, of 150 Broadway. It contains descriptions aud illustrations of an excellent variety of line fixtures, trolleys, etc., and includes a number of novelties, such as their double fusible safety box and their renewable wooden teeth gear, with which latter they have supplemented their metal gears of all kinds.

MR. GEORGE W. LA RUE.

The Crocker-Wheeler Electric Motor Company has secured as sales agent Mr. George W. La Rue, whose long and successful connection with the Sprague Electric Railway and Motor Company as agent in the East, is sufficient guarantee that the Crocker-Wheeler perfected motors will be found at the head of the procession.

THE RAE ELECTRIC RAILWAY SYSTEM.

The Detroit Electrical Works are reported by Mr. C. A. Benton, the general manager, to be busier than ever, filling orders for electric railway equipments. They have sold during the past week four more outfits, namely, two for the Richmond & Manchester Railway, of Richmond, Va., and two for the Augusta, Ga., Railway Co. Both these are equipped already with plant of another make. Mr. W. A. Stadelman, the company's Philadelphia agent, secured these contracts.

NEW YORK GOSSIP.

Wm. E. Davis, late of the engineering department of the Edison Company, is now superintendent of the Toronto Incandescent Electric Light Company and has located there permanently.

The India Rubber & Gutta-Percha Insulating Wire Company have removed their offices to 315 Madison avenue, corner of 42d street, and are comfortably installed in their new quarters and ready to meet their old friends at the above address.

WESTERN TRADE NOTES.

Mr. Edward R. Grier, brother of Thos. G. Grier, engineer of the National Engineering Bureau, and well-known in electrical circles in the West, has been appointed superintendent of the Southern Electric Company, of Philadelphia, Pa. He was formerly associated with the North American Construction Co., which well-known concern was evolved from the old Marr Construction Co. Mr. E. R Grier was one of the experts on the Hoosic Tunnel installation of the Westinghouse system, which was one of the notable plants of the country when put in, and he invented the joint used on the lead covered cables employed in carrying out that work. He was also electrical expert on the private residence plant of George Westinghouse.

Mr. George Cutter, the "Electrical Specialist" of the West, will once more handle the famous "Simplex" wires and cables. He will carry a large and extensive stock of all sizes in the Rookery, where he has secured ample space in the basement for the purpose; and all orders will receive that prompt attention and despatch for which Mr. Cutter is noted.

Mr. J. S. Spruance, of the Star Electrix Co., of Philadelphia, Pa., was a recent welcome visitor to Chicago. He visited on his trip Minneapolis, St. Paul, and other Western cities and found Star Electrix specialties in demand everywhere.

Mr. G. A. Edward Kohler, the representative of the Eddy Motor Co., of Manchester, Conn., reports the following sales of motors during the past month: Five 2 h. p.; one 3 h. p.; three 5 h. p.; one 7½ h. p, and two 10 h. p. machines, making an aggregate of 55½ h. p. This record shows how rapidly these motors, which embody such excellent mechanical, electrical and scientific principles in construction, are finding wide employment and favor in the West.

The Illinois Electric Material Company, Roo
Chicago, have brought out a new catalogue which is ac
something unique in its line. The printing in color and t
raphy is unique, the arrangement of the many standard a
and specialties which they handle is also unique, and lastl
opening of the book which presents the two pages to the r
at once, it being read from top to bottom, down both she
unique. It reflects the greatest credit on Mr. Ernest Hoefe
general manager of the company, who got it up, as being
thing of a decidedly handy size and novel form and is espe
adapted to being found in the pockets of the purchasers of
tric light power or railway supplies, from which it will also
the weighty silver dollars in exchange for the enticing good
played in its pages. Truly it is a pleasant thing to see a
novel catalogue.

Mr. D. B. Dean, so long and favorably known as the en
and versatile Western representative of the *Electrical Rev*
New York, has resigned his position with our esteemed co
porary, and has accepted a position as traveling representa
the Electric Merchandise Co., of this city. His wide acquai
and pushing qualities peculiarly fit him for his new sph
work. He will find himself in congenial companionship wi
W. R. Mason, the manager of the Electric Merchandise Co
Mr. Dean will make a highly active and efficient representa
that well known concern.

Mr. H. Jenkins, who until recently has been associate
the National Engineering Bureau, has now connected h
with the Pond Engineering Co. and will shortly proc
Omaha, where he will take charge of their office. Mr. Jen
a hard worker, full of energy, and push and will make his
in the engineering business in Nebraska and neighboring
tory.

The Chicago Rawhide Manufacturing Co., 75 and 7
street, Chicago, are meeting with great success with the
hydraulic rawhide packing, which they manufacture. Thi
ing has many marked advantages particularly in wearing
ties, and is easily compressed, being a soft packing, thereb
pensating for its slight wear. It will not cut a rod, plun
cylinder, on account of the method of curing the rawhide,
causes it to act as a lubricant and effect a notable saving in
It is adapted for all purposes where a cool water pac
employed for freezing, hydraulic machines and the like.

Mr. Crolius, of the Globe Light and Heat Co., Michigan
Chicago, is very busy extending the electrical specialty
ment of the company. They will bring out a number
designs in fixtures and so forth for electrical work, and ar
a brisk and increasing business.

NEW ENGLAND TRADE NOTES.

Claflin and Kimball have opened an office at 116 B
street, Boston, and will hereafter act as general agents
Perkins Electric Lamp Company, of Manchester, Conn., a
conduct the entire selling department of that company.
respondence should be directed to them regarding sale
chase of Perkins incandescent lamps, when it will rece
same prompt attention as heretofore.

Mr. W. C. Fish, who has recently returned from
years' trip to the other side of the water, where he has be
mately connected with electrical enterprise, has recently
associated with Mr. H. B. Cram in the management of th
stein Electric Company, of Boston. Mr. Fish's wide exp
and accurate knowledge of the wants of the electrical fra
should make him a valuable acquisition to the B
Company.

The Buckeye Electric Company, of Cleveland, O
opened a New England office, at 85 Water street, Bosto
Mr. Louis R. Wallis as resident New England agent. Mr.
is well acquainted with the incandescent lamp business,
been for several years connected with the Bernstein Elec
and he already reports a large demand for the Buckeye la

The Gould and Watson Company, the well-known de
mica, and manufacturers of moulded mica insulator
opened a branch office at 170 Washington street, Chicago
the management of Mr. R. B. Pierpont, who has been co
with them for some years in Boston. The demand for
mica still grows, and it has now got to be regarded, from
of experience, as one of the very best insulators known.

The Shipman Engine Company, of 200 Summer street,
have recently shipped one of their four horse power autom
gines to Don Carlos Pacheco, Vera Cruz, Mexico, for driving
electric dynamo, and a two anda four horse power engine t
lulu also for electrical purposes. The Shipman automatic
uses kerosene for fuel, and is made with boiler and engin
plete. They are made in sizes of from one to eight horse
and are simple, durable and efficient. They are admirably a
for running small electric plants, requiring no skilled c
making no dirt or dust.

FOR L CIRCUITS.

5 h. p.; one 7½ h. p., and two 10 h. p. machines, making an aggregate of 55½ h. p. This record shows how rapidly these motors, which embody such excellent mechanical, electrical and scientific principles in construction, are finding wide employment and favor in the West.

uses kerosene for fuel, and is made with boiler and engine complete. They are made in sizes of from one to eight horse power, and are simple, durable and efficient. They are admirably a dapted for running small electric plants, requiring no skilled care, and making no dirt or dust.

THE
Electrical Engineer.

VOL. XI. FEBRUARY 25, 1891. No. 147.

L. RMINATION OF SELF-INDUCTION COEFFI-C. T BY MEANS OF A WEBER INDUCTOR.

BY

Samuel Sheldon

I HAVE never seen in English the following simple method for determining L by means of an inductor and a differential ballistic galvanometer. It was presented in 1887 to the class in mathematical physics at the Munich Academy of Sciences by F. Kohlrausch.

For the determination, use is made of the curious fact that, when a momentary induced current is equally divided through the two coils of a differential ballistic galvanometer, and when one of the branches contains an inductive resistance, the needle of the galvanometer will give an instantaneous deflection without any velocity at its close. This deflection is started by the inverse extra current in the one coil of the galvanometer, and is stopped by the opposite direct extra current. The magnitude of this deflection can be easily measured by means of a telescope and scale.

The arrangement of apparatus is shown in the diagram. E R is a Weber inductor, consisting of a hollow coil and two magnets with like poles opposed to each other. The magnets are fastened together "end on," and upon pushing them into the coil, a certain E. M. F. is produced. From one terminal of the coil the induced current divides through two paths, passing around the two galvanometer coils in opposite directions. One path contains the resistance r, whose self-inductive coefficient is to be determined, and the other contains an equal non-inductive resistance r'. The equality is obtained by previously employing a battery of constant voltage. At any instant of time t, let E and R equal the E. M. F. and resistance, respectively, of the inductor; $g =$ the resistance of each galvanometer coil; $i =$ the current in the resistance with self-induction and i' the current in the non-inductive branch. A little consideration will show that the E. M. F. of self-induction is

$$L\frac{di}{dt} = (i' - i)\,(r + g) \text{ or}$$

$$i' - i = \frac{L}{r+g}\,\frac{di}{dt}. \qquad (1)$$

This current excess, in the one coil of the galvanometer, gives the needle an acceleration

$$\frac{d^2 x}{dt^2} = C(i' - i) = \frac{L}{r+g}\,C\,\frac{di}{dt},$$

where C is a galvanometer constant. If the needle was at rest at the beginning of the impulse, then we have further,

$$\frac{dx}{dt} = \frac{L}{r+g}\,C\,i.$$

Now, since at the close of the impulse $i = 0$, the velocity of the needle is also 0; during the whole impulse, however, the needle has made a deflection,

$$x' = \frac{L}{r+g}\,C\int i\,dt. \qquad (2)$$

Now $i = \dfrac{E}{2R + r + g}$, and therefore,

$$\int i\,dt = \frac{1}{2R + r + g}\int E\,dt.$$

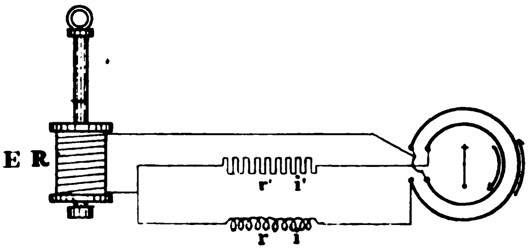
Substituting this value in (2) we obtain[1]

$$x' = \frac{L}{r+g}\,\frac{1}{2R + r + g}\,C\int E\,dt. \qquad (3)$$

In order to determine the value of $C\int E\,dt$, send a full impulse from the inductor through one of the galvanometer coils, having previously inserted a sufficiently large resistance R' in the circuit. The current then at any time t, is $I = \dfrac{E}{R + R' + g}$, which gives to the needle an acceleration $\dfrac{d^2 x}{dt^2} = C\,I = \dfrac{C\,E}{R + R' + g}$ and, at the close of the impulse, the velocity of the needle is

$$v = \frac{C}{R + R' + g}\int E\,dt, \qquad (4)$$

which causes a deflection x of the needle. Let $k =$ the damping constant of the needle; l (= nat. log. k) = natural logarithmic decrement in the experiment; and $T =$ time of oscillation of the undamped needle. Then set



$$k^{\frac{1}{\pi}\arctan\frac{\pi}{l}} = S. \qquad (5)$$

and the ordinary formula for ballistic galvanometer work gives us

$$v = x\,\frac{\pi}{T}\,S = \frac{C}{R + R' + g}\int E\,dt,$$

$$\text{and} \quad C\int E\,dt = x\,\frac{\pi}{T}\,(R + R' + g)\,S. \qquad (6)$$

Placing this in (3) and transforming, we have,

$$L = \frac{x'}{x}\,\frac{T}{\pi}\,(r + g)\,\frac{2R + r + g}{R + R' + g}\,\frac{1}{S}. \qquad (7)$$

In order to determine L we have then, besides observing the deflections x and x' to measure the resistance, and the time of oscillation and the decrement of the needle. These last can be determined sufficiently from a few swings of the needle.

An error from a slight lack of symmetry in the galvanometer coils can be eliminated by making two determinations with exchanged connections and then averaging them.

The determination can be carried out equally well with a *differential inductor* and an ordinary single coiled galvanometer, the derivation of the formulæ being very similar to that given.

---

[1] If we take account of the mutual and self-induction in the rest of the circuit, we arrive eventually at the formula given here.

If the resistances be expressed in ohms, the coefficient will be in secohms; if in centimetre-seconds, it will be in henry's.

ELECTRIC POWER TABLE AND CURVES.

The accompanying curves and tables, prepared by the Massachusetts Electrical Engineering Co., of Boston, will be found of very great value to all electrical engineers, station men, and electricians generally. The tables are designed especially for 500 volt power circuits, and give the horse-power when the pressure and current are known. For less accurate work, the curves given in Fig. 1 may be used. On these, the abscissæ represent amperes, and the ordinates, volts. The nearest curve to a point obtained with any given pressure and current, is the nearest horse-power. By interpolation, a result sufficiently close for general use may be obtained. Thus, taking a circuit carrying 60 amperes at 500 volts, the lines intersect on the curve marked 40 h. p.

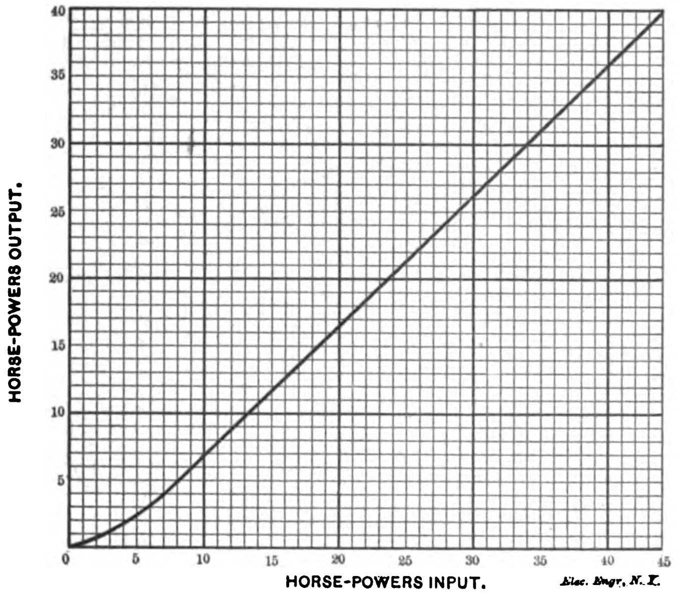


Fig. 2.—Curve for Determining Input and Output of Motors.

It is needless to add that the curves and tables may be used below and above the range given. By mentally displacing the decimal point in either direction, the values may be increased or decreased ten or one hundred fold, etc., thus greatly extending the range.

It is also evident that the volts and amperes are interchangeable, and can be taken from either the vertical or horizontal columns, respectively.

To illustrate how simple and convenient the use of electric power may be made to those comparatively ignorant of its principles, we show such a curve, Fig. 2, as is furnished by the Massachusetts Electrical Engineering Co. for power plants, to be used in connection with the horse-power tables and curves.

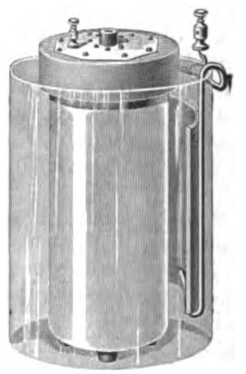
Near each motor is placed a table or curves of horse-powers similar to those here given. The attendant at any time, reading the pressure and current, determines the horse-power delivered to the motor by reference to the tables or curves. Finding this point on the "input" side of the curve, Fig. 2, he determines the "output," or power required by the machinery driven, by following the line to the vertical column on the left. Thus, 20 h. p. input intersects the curve at a point, which, if followed to the left, will give 16.5 h. p. output.

This curve is based on the efficiency of the motor at various loads and is determined by careful tests. The curve shown is that for a forty horse-power motor. A similar curve drawn for a generator would show the power delivered by the engine at any time.

THE TAYLOR PRIMARY BATTERY.

While the gravity battery leaves little to be desired so far as constancy of action is concerned, it is evident that for local work, such as the driving of small motors, the running of incandescent lamps, etc., the use of that type of cell is out of the question on account of its high resistance and its comparatively low E. M. F. With the object of producing a cell which should be constant in its action for a continuous period of time and at the same time be of low resistance and high E. M. F., Mr. T. F. Taylor has recently designed a cell which is illustrated in the accompanying engraving.

One of the distinguishing features of the Taylor battery is that the zinc is entirely immersed below the surface of the exciting liquid, being held in position by a light frame, which remains unattacked. Instead of a single carbon, as heretofore generally employed, Mr. Taylor uses a series of carbons which are connected together and to the external circuit by a joint which is not attacked by the solution employed.



The Taylor Primary Battery.

The depolarizing liquid is contained in a porous cup made of a special material, and while entirely replacing nitric acid has none of the qualities which attend the use of the latter. This depolarizing solution is made up by the addition to water of a powder and which can thus be readily shipped, and the solution prepared at the place where the battery is used.

The cell has a very low internal resistance, the No. 1 cell, measuring 12x7 inches, having only .08 ohm. The E. M. F. of the cell is 2 volts, so that on short circuit it gives a current of 25 amperes, which can be maintained throughout the life of the solution. Three of these cells are sufficient to maintain a 3 c. p. lamp brilliantly lighted for 160 hours, and are sufficient to run an 8 h. p. motor. The No. 2 cell, 8x5½ inches, gives a current of 8 amperes; and the "Amateur" battery, 3x3½ inches, is sufficient to light a small Edison lamp for several hours. These cells, which are manufactured by Messrs. Taylor & Son, of this city, have already attracted considerable attention and seem well adapted to the work for which they are intended.

F. H. Thompson, late with the Marr Construction Company, is now superintendent of the Spanish-American Light and Power Company, Consolidated, at Havana, Cuba, and a letter lately received from him says that they have a station now of 7 150 h. p. boilers and an engine capacity of 1,000 h. p., and that the station is now complete and working in the most satisfactory manner.

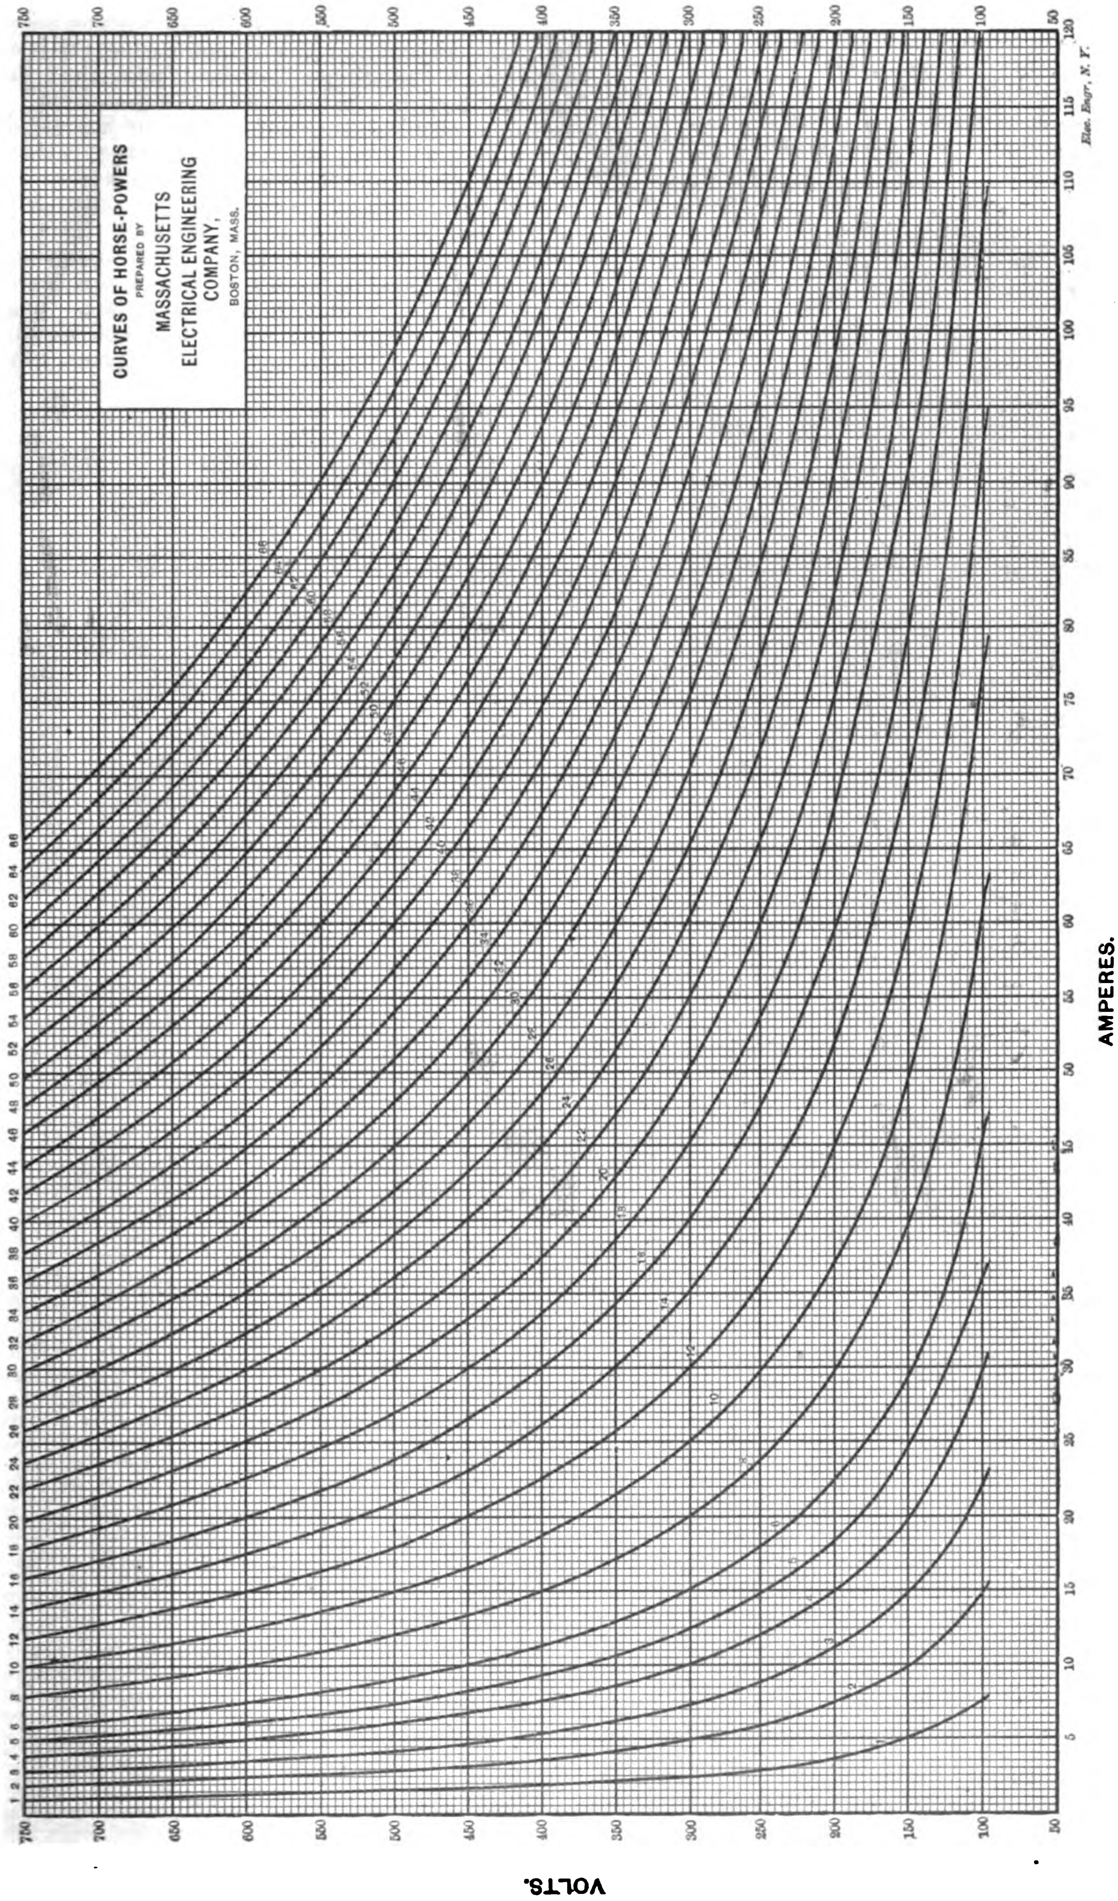


Fig. 1.—Curves for Determining Horse Powers at Various Currents and Potentials.

THE NEW CARD ARC MOTOR.

As OUR readers are aware, the Card Electric Motor and Dynamo Company, of Cincinnati, Ohio, have for some time devoted considerable attention to the construction of motors designed to be operated on arc circuits. Such machines, as a rule, are governed on a principle somewhat different from that employed in constant potential motors. The accompanying illustration, Fig. 1, shows the new arc motor just designed by the Card Company. The field, it will be seen, is of the consequent pole type, the field magnets consisting of two cylindrical coils which are wound on bobbins and slipped on the cores.

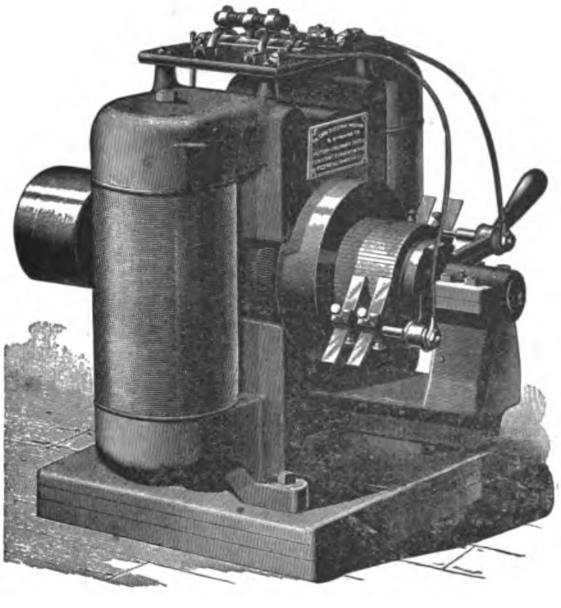

FIG. 1.—THE CARD ARC MOTOR.

The governor of the machine, which is placed at the top, is shown in detail in Fig. 2. It consists of a centrifugal governor, which is attached to the armature, and is actuated by any variation in its speed, an increase causing the field magnetizing coils to be opened and the circuit completed through the armature. The governor is so sensitive that in actual service there is no perceptible change of speed. It will readily be seen that with this governor the motor consumes current only in proportion to the load. A further advantage claimed is, that by simply turning a hard rubber button, the speed of the arc motor can be adjusted to 500 revolutions per minute slower or faster than the regular speed.

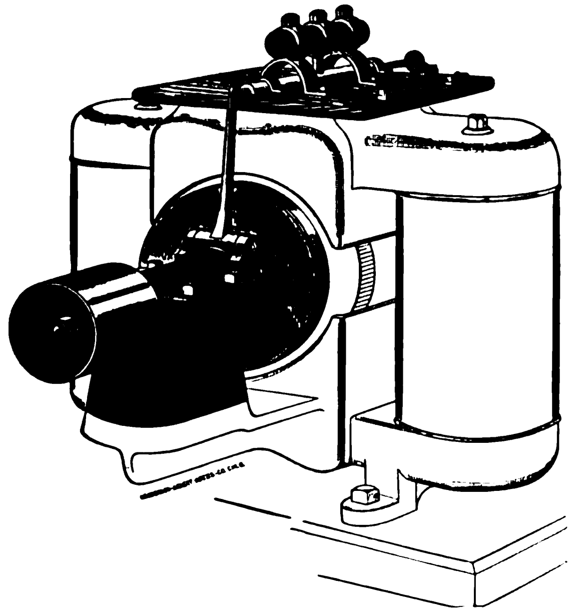

FIG. 2.—AUTOMATIC GOVERNOR OF CARD ARC MOTOR.

The mechanical design of the motor has also been very carefully worked out and a special feature is the self-oiling bearing employed. This is shown in detail in Fig. 3. As will be seen, the shaft is enclosed in a sleeve having a slit at the bottom, which permits a wheel to roll in contact with it. The lower half of this wheel dips in an oil reservoir, which forms the lower portion of the bearing and as a result of the revolution of the shaft a continual stream of oil is taken up by the small wheel and supplied to the shaft. After doing its work the oil passes to the end of the sleeve and returns to the reservoir below by the ducts at either end. These machines are built in various sizes and for the various currents employed on arc circuits.

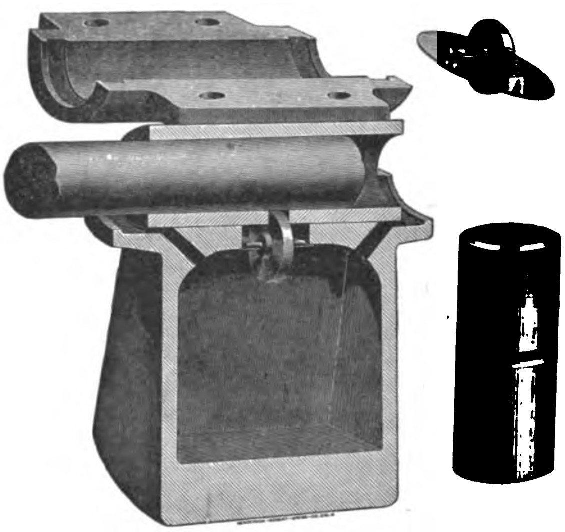

FIG. 3.—SELF-OILING BEARING OF CARD MACHINE.

Reports of Companies.

FEDERAL TELEPHONE COMPANY.—At the annual meeting of the Federal Telephone Company, held at Montreal, P. Q., on the 11th, the old Board of Directors was re-elected, with W. Cassills as president; J. Forget, vice-president, and J. Wright, manager.

WISCONSIN TELEPHONE COMPANY.—The following officers were elected by the Wisconsin Telephone Company at its annual meeting on the 9th inst.: President, H. C. Payne; vice-president, C. H. Haskins; secretary, J. D. McLeod; treasurer, F. G. Bigelow. Directors, F. G. Bigelow, G. Albree, of Chicago, B. K. Miller, H. C. Payne, C. H. Haskins, C. Ray and D. M. Benjamin, the two last being an addition to the number of those elected last year.

VERMONT INTERNATIONAL TELEGRAPH COMPANY.—At the annual meeting of the Vermont International Telegraph Company, held at St. Johnsbury, Vt., the following officers were re-elected: F. Fairbank, president; G. W. Hendee, secretary; E. A. Silsby, superintendent.

COMMERCIAL UNION TELEGRAPH COMPANY.—At the annual meeting of of the Commercial Union Telegraph Company of Maine, held at Portland on the 11th, the following directors were elected: H. S. Osgood, F. A. Dow, A. Little, S. R. Small, of Portland, H. Russell, E. J. Slattery, C. E. Arnold, of Albany, J. W. Wakefield, of Bath, G. C. Wing, of Auburn, and W. D. Pennell, of Lewiston.

ADIRONDACK TELEGRAPH AND TELEPHONE COMPANY.—At a meeting of the stockholders of the Adirondack Telegraph and Telephone Company, the following officers were elected for the ensuing year: J. W. Burdick, C. H. Erwin, W. C. Humstone, W. F. Weston, and H. L. Waterbury.

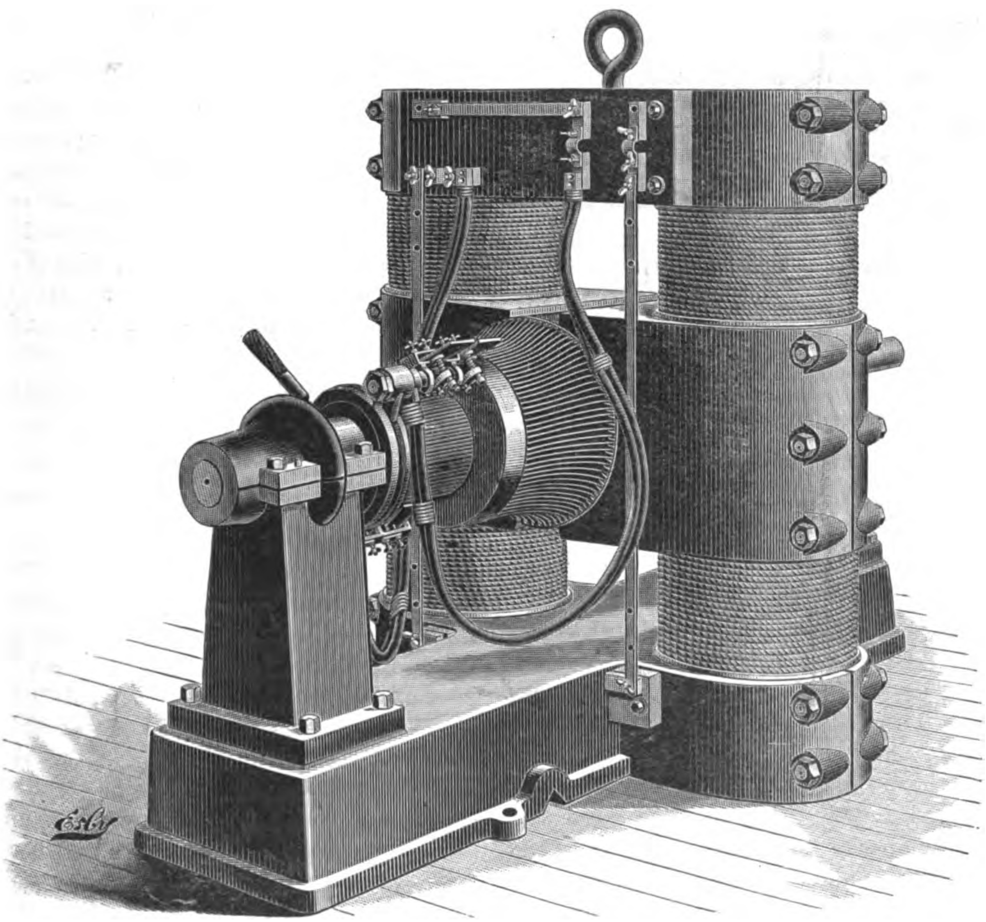
BAIN'S NEW RAILWAY AND POWER GENERATOR.

The long lines employed in electric railways and in electric power for stationary motors, have in the past frequently led to a considerable drop in potential when the demand for current was heavy, and as such a drop, means a slowing down of speed and power of the motors, just when the most power is required, some means of keeping the potential constant, and, indeed, raising it with increased loads, was desirable.

To effect this object, Mr. Foree Bain, of Chicago, has designed the machine illustrated in the accompany engraving. The generator which is specially designed for railway and stationary power circuit work is of 160,000 watts capacity at 500 volts, and weights ten tons.

The machine is compounded for a rise in potential of ten per cent. on full load. There is only 720 feet of wire on the armature, the internal resistance of which is .0184 ohm; the shunt field resistance is 365 ohms, thus giving about 1$\frac{1}{5}$ per cent. loss due to the internal resistance of the armature at full load, and less than one-half of one per cent. loss in the shunt field, and about an equal loss in the series field, thus demonstrating its excellent design and high economy.

One of the special features of all the large types of dynamos of Mr. Bain's design is that each coil on the armature is precisely of equal length, and has an insulated and positive driver firmly attached to the core, and on the large machines there is in addition an air space entirely around each wire on the armature. The dynamo is substantially built with heavy wrought iron cores, and the field coils are wound on spools and slipped over the core. The commutator is ample in size and made of pure copper, and the machine has self-oiling bearings. We may add that the Bain Electric Manufacturing Co. are prepared to build dynamos up to 400,000 watts, or 500 h. p. capacity.



BAIN'S 160,000 WATT RAILWAY AND POWER GENERATOR.

ON PHOTO-ELECTRICITY.[1]

At a recent meeting of the Physical Society, Prof. G. M. Minchin, M. A., read a paper on "Photo-Electricity," giving the result of his experiments since 1877, which, while they have not hitherto attained the object sought, have led to the discovery of many interesting phenomena.

He showed that when two silver plates coated with collodion, silver salts, or aniline dyes, are immersed in a suitable liquid, and one plate illuminated while the other is screened, electric currents are produced, having a photographic effect upon the plates.

With some cells, curious reversals take place, the exposed plate being first positive and then negative, while an increase of current, which afterward gradually disappears, results from shutting off the light. The E. M. F. of these cells rarely exceeds $\frac{1}{10}$ of a volt.

Pieces of tin foil having one side dull and the other bright, pasted on opposite sides of a piece of glass in such a manner that dissimilar sides are exposed, and immersed in alcohol, give an E. M. F. of $\frac{1}{18}$ volt, when the dull side is exposed to the light. Uncleaned tin foil plates in common tap water, also give a current, which is destroyed on cleaning the plates. Usually the exposed plate is first positive and then becomes negative, and by exposing various portions of a plate, the direction of the current may be varied. These phenomena may explain the known divergence of tin from Volta's law. A process of making very sensitive plates was described, which apparently results in the formation of a white oxide of tin on the surface of the foil. It is found that the square of the E. M. F. is proportional to the intensity of the light.

Sometimes a good cell will exhibit no E. M. F. after having been kept for a few days. When this is the case, a slight tap will restore its sensitiveness, while another tap will again destroy it, and so on. These are called impulsion cells. The sensitized plate of one of these cells had different properties at its two ends, for impulses had no effect on the nature of the lower end, but changed the upper end from positive to negative and *vice versa*. Electromagnetic impulses, such as produced by sparks, are capable of altering cells from the unsensitive to the sensitive state, but fail to produce the reverse effect; a Hertz oscillator restored the sensitive state in a cell placed at a distance of 81 feet away. The "impulsion effects" can be got rid of by renewing the alcohol on several successive days.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XI. NEW YORK, FEBRUARY 25, 1891. No. 147.

"Let it be our ambition, then, as it is our duty, to supply every demand for every kind of light and power service within reach of our stations.—Prest. Marsden J. Perry.

PEACE AND PROGRESS IN THE N. E. L. A.

THE Convention just held by the National Electric Light Association, at Providence, was beyond question the most successful in the history of that body. The registry kept by THE ELECTRICAL ENGINEER showed an attendance of 450, while there were about 50 ladies, making 500 persons present actively interested in the Association's work and future. The meetings were also attended by a large number of curious citizens, while the exhibition was crowded to suffocation at all hours. The papers were numerous and good, and the Decennial exercises were a novel and attractive feature not without merit of a kind.

So well pleased are we with the work of the Convention that we have little but praise to bestow; still it does seem that a word or two of suggestion may not be amiss. The tendency of the proceedings of a body with so many allurements into new territory is a centrifugal one, perhaps for the main reason also that a varied programme is the more likely to attract a large audience. Now, on the contrary, it should not be forgotten, and should ever be borne in mind, that the Association is intended to voice and enforce the views of local electric lighting and power companies, of which there are now at least 1,500 in this country. The operation of even the largest isolated plant entitles only to associate membership. Yet the list of subjects treated last week does not suggest any such idea. The programme traversed all creation and would not leave the impression that they who had come together had as their object the promotion and protection of central station interests.

The results of this diffuseness and indefiniteness of plan are readily to be detected. While everyone of the papers and addresses was full of meat, those which actually touched questions vital to the central station owner and superintendent got but scant time and attention. Mr. T. C. Smith's paper deserved a thorough discussion, and a whole day would not have been too much. Unfortunately it came late, and thus a golden opportunity was lost. Then Dr. Bell's report on the rating of incandescent lamps ought to have brought up a number of valuable points and hints; but it went by, at the fag end of a long day, without a whisper of comment. The report on legislation was extremely interesting, but that, too, was cut short by nightfall.

All of us want to see the Central Station men enrolling themselves, but they will not do it unless the subjects are such as come right home to their pockets and will add to their fund of experience and information. It is not a hard thing to name a dozen topics that are of first importance to central station men, and which could be discussed, in either open or executive session, with the utmost benefit.

Aside from this criticism, the results of the meeting are subject only to congratulation. The utmost harmony and kindly feeling prevailed, a good man of the best stamp was selected for president, and no one could ask for a more acceptable place of summer meeting than Montreal.

CENTRAL STATION BYE PRODUCTS.

The unreasonable clamor for reduction in rates of electric lighting, especially by many city authorities, has made it necessary for not a few companies to practice the strictest economy, and to this may, indeed, be traced some of the unfortunate affairs which have prejudiced electric lighting in the minds of the public. Aside from this, however, it seems eminently proper to consider whether the income of an electric light station cannot be increased legitimately by the utilization of what in many instances may be considered as power wasted in the exhaust steam.

Few stations are so favorably situated that condensing engines can be profitably employed, and hence the majority are in a position to entertain the subject of exhaust steam distribution. Mr. Prentiss has set forth very ably in the paper read at Providence, the conditions to be fulfilled in carrying out a scheme of this kind, but, as he remarks, each case requires special consideration to determine whether the commercial utilization of the exhaust steam can be successfully carried out. While, therefore, presenting an excellent opportunity for increasing the revenue of a station, where it can be applied, we believe that a move in this direction should only be made after the most careful study of the existing conditions. It is evident that a false step may not only reduce the profits of a paying station, but involve the sinking of capital which might, with good advantage, have been expended on improvements and extensions of the electric light plant itself. If such new work be undertaken, however, competent engineers, ought to be employed and consciencious work must be insisted upon in every detail.

THE HOSPITALITIES AT PROVIDENCE.

It would not be right to pass away from the Convention proceedings at Providence last week without acknowledgment of the endless courtesies and hospitalities of the occasion. President Perry and the proprietors of the American Electrical Works did all in their power to promote the general comfort, and their special efforts in the two receptions, on Wednesday and Thursday evenings, were simply perfect. Another pleasant feature of the meeting was the opportunity afforded of visiting some of the most celebrated factories in the country, where engines, silverware, machinery, and fine tools are made not only for home consumption but for a large and growing foreign demand. At each of these vast establishments the same cordial welcome was extended, and the principals themselves gave up their valuable time to escort their guests.

THE ELECTRIC ARC.

It is a curious fact, but none the less true, that the literature relating to the one of the oldest and most applied electrical phenomena has practically remained without notable addition since its first recorded publication. We refer here to the electric arc as such, and the phenomena observed in its operation in electric lighting as dependent upon the nature of the mechanism employed, including both dynamo and lamp. Probably no one is better able to bring out the various points of interest and importance than Prof. Elihu Thomson, whose first successes were attained in the field of arc lighting, and who has now found an opportunity of laying what must evidently be only a small part of his observations, before the National Electric Light Association. Regarding the explanation of the light-giving qualities of the arc, Prof. Thomson lays stress upon the fact that writers, even of quite recent date, have entirely forgotten, or have not known, that the principal source of illumination is the carbon vapor generated by the intense heat of the arc. The reasons which led Prof. Thomson to the utilization of the long arc in preference to the short, aside from the saving in line conductors effected by its use, are those which have probably been noted by the majority of experimenters in this direction, and are presented by him in a very concise manner. The insertion of resistances in the circuit of arc lamps operated on constant potential circuits, first practiced in connection with naval search lights, as a mere reducer of potential, was soon found to be a necessity to obtain smooth working, and the reasons for this, as stated by Prof. Thomson, go to vindicate his belief in the uselessness of attempting to operate such lamps successfully without this adjunct, made necessary by the inherent nature of the arc itself. For those who contemplate the designing of arc machines, the part of Prof. Thomson's paper relating to the arc dynamo will prove of great value, as showing the conditions which must be met in order to avoid "surging" of the lights, and which require qualities in the dynamos almost diametrically opposite to those exacted from constant potential machines. As Prof. Thomson expresses his belief in the equal fitness of closed and open circuit armatures for the purposes of arc lighting, it is fair to assume that the reasons which determined the retention for so long a time of his original three-coil armature and three-part commutator, together with its peculiar style of field, were based on good reasons, among which simplicity of construction and ease of maintenance were justly, we think, given a prominent place. The more general knowledge of electrical machinery, and the larger number of competent men available to take charge of electrical plants, has no doubt determined the departure which, we understand, has been recently effected in the Thomson-Houston apparatus in the substitution of the Gramme ring armature for the three-coil open type, so successful in the past.

Prof. Thomson's multiple carbon arc experiments will also prove of interest, and we hope that the hints thrown out by the brilliant author of many such facts and experiments still to be published, will soon be followed up by a further communication on this subject.

A Discussion on Rapid Transit.

The Electric Club of this city, with a keen appreciation of one of its many functions, has wisely decided to devote the discussion after its monthly dinner on Thursday, Feb. 26, to the very important topic of Rapid Transit. A number of leading citizens are expected, while all the various methods of carrying passengers in cities will be represented, and street railway interests will also be heard from. That the electrical side of the question will also be taken care of in the symposium is evident from the fact that it will be put forward by such men as Mr. Frank J. Sprague, Capt. Eugene Griffin, and Mr. Edward Weston. The occasion is one that all members of the Club should participate in, and we are glad to know that a very large attendance is expected. The dinner is at 6:30 at the Club House.

Testing for Faults in Underground Cables.

Probably no work in connection with the operation of central electric light stations requires more care and constant supervision than an underground system of conductors, and there is none which involves more trouble in repair when a fault develops at a point midway between terminals or junction boxes. The low resistance of the conductors employed makes the exact location of a fault exceedingly difficult, and any method by which this can be accomplished in any easy manner will, we are certain, be welcomed by many. The test described by Mr. B. T. Burt in our issue last week, which he has used with so much success in Bilbao, Spain, seems readily applicable to many cases of this nature and is sufficiently simple to be undertaken by those who have but slight acquaintance with the manipulation of electrical testing instruments.

100 Pages and Supplement Again.

Last week The Electrical Engineer consisted of 100 pages and a supplement. This week it is exactly the same size, making a total of 200 pages and 2 supplements printed and distributed in ten days. Having had some spare copies of the Cleat and Horse Power Supplements printed, we shall be glad to send an extra copy of each to any of our readers, free of charge, upon application, until the supply is exhausted.

THE B. & S. CEILING ROSETTE CUT-OUT.

The want felt by both contractor and consumer for a rosette which is easy to install, convenient to use, and handsome in appearance, has led the B. & S. Electric Equipment Co. to design the ceiling cut-out shown in the accompanying illustrations. In these Fig. 1 shows the construction of the device. As will be seen, the circuits are connected to strips having curved tongues. The flexible cord is attached to binding screws in the cap, which, in their turn, are connected by means of fusible wires to two projecting clips at the sides. A half turn of the cap causes these clips to engage with the curved tongues in the base, making a perfect rubbing contact, and holding the cap firmly in position, as shown in Fig. 2. The rosette is made of a fire and waterproof material exactly resembling hard rubber, and while having the good qualities of porcelain, is free from its brittleness and lack of finish.

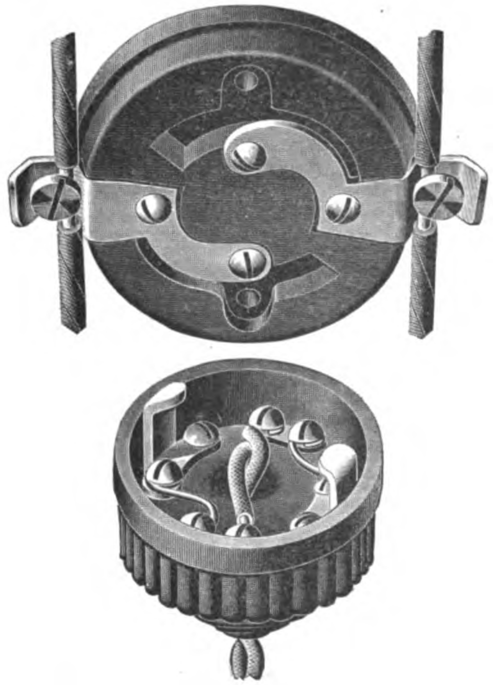

Fig. 1.—The B. & S. Rosette Cut-Out.

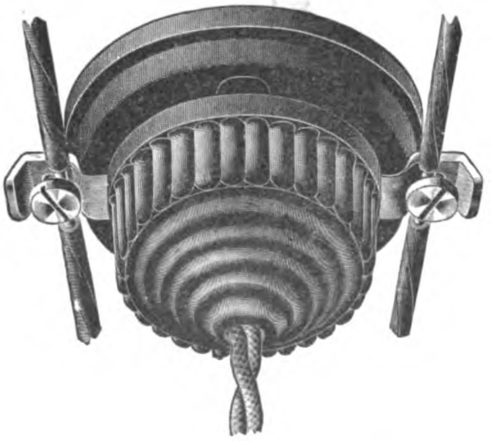

Fig. 2.—The B. & S. Rosette Cut-Out.

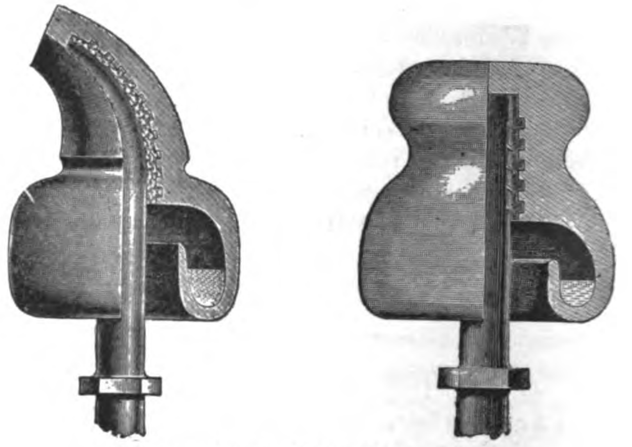
Boynton' Bicycle Railway Company.—At the annual meeting held on February 11th, it was decided to organize an electric sub-company, with a capital of $500,000, similar to the Bicycle R. R. Co., and to act in harmony with it. A 100 per cent. stock dividend was declared payable May 1. The following officers were elected for the ensuing year: President, E. M. Boynton; vice-president, Dr. J. B. Bell; secretary, W. H. Boynton; assistant secretary, A. B. Boynton.

FLUID INSULATORS.

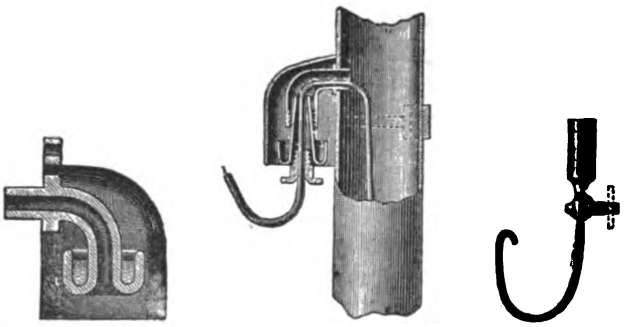
The accompanying cuts, Figs. 1 to 5, illustrate a type of insulator comparatively unknown in the United States, though used in other countries. They are manufactured by Johnson & Phillips, of London. These devices were designed for the purpose of obtaining the highest insulation by preventing surface leakage. An insulating fluid which, it is stated, will not support a film of dust or moisture, fills a recess, well protected from the weather, in the porcelain body of the insulator. In this way a clean and highly-insulating fluid surface is interposed between the line and earth. The insulators are found to be especially efficient in rainy weather.



Figs. 1 and 2.—Fluid Insulators.

These insulators, which are made in numerous patterns of either porcelain or brownware, may be employed to advantage on coast lines, where the glass or porcelain quickly becomes coated with a conducting film of salt.

The insulation fluid is manufactured by Johnson & Phillips, London, under a secret process. The fluid, it is claimed, does not freeze; it does not evaporate; and allows dust to sink to the bottom: it does not creep like paraffin or other mineral oils and lasts three or four years, even in the East Indian climate. One gallon of the insulation fluid suffices for about 20 of the smaller and 15 of the larger insulators. These insulators are handled by the Electrical Supply Company, of Chicago.



Figs. 3. 4 and 5.—Fluid Insulators and Filling Tube.

HIGHLAND PARK ELECTRIC R'Y., DETROIT, MICH.

The Highland Park R'y. was equipped by the Detroit Electrical Works with the Rae system in July, 1890. The following report of the operation of the cars is made by Superintendent Lewis, Dec. 31, 1890:

Car "Ampere":—Placed in service, July 13, 1890; No. days, 150; average miles per day, 122 4-15; total miles 18,340. Repairs, 2 brass sleeves placed in armature bearings in December.

Car "Volta":—Placed in service, July 13, 1890; No. days, 143; average miles per day, 109; total miles, 15,000. Repairs, 1 brass sleeve replaced in armature bearing in December.

Car "No. 6":—Placed in service Oct. 12, 1890; No. days, 52; average miles per day, 118 31-52; total miles, 6,167. Repairs, none.

Hartford Electric Light Company.—The directors of the Hartford Electric Light Company, have re-elected A. C. Dunham, president, and H. M. Clark, secretary and treasurer.

THE ELECTRIC ARC AND ITS USE IN LIGHTING.[1]

BY ELIHU THOMSON.

It is curious that notwithstanding the fact that as a source of illumination the electric arc has been known since the beginning of the century, the scientific study of its nature has been but little pursued. It began to be known as a sort of scientific curiosity, being at first set apart as one of the many phenomena observed in the use of powerful batteries. It was not until about twenty years after its discovery by Sir Humphrey Davy that any proposals were made to use it in lighting, and, subsequently, for many years it was occasionally employed either in lecture demonstrations or in obtaining an intense light for some special purpose.

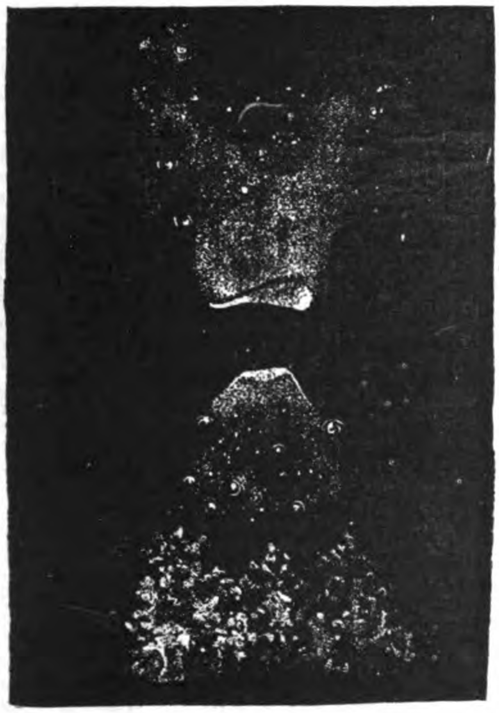


FIG. 1.—OLD REPRESENTATION OF ARC CARBONS.

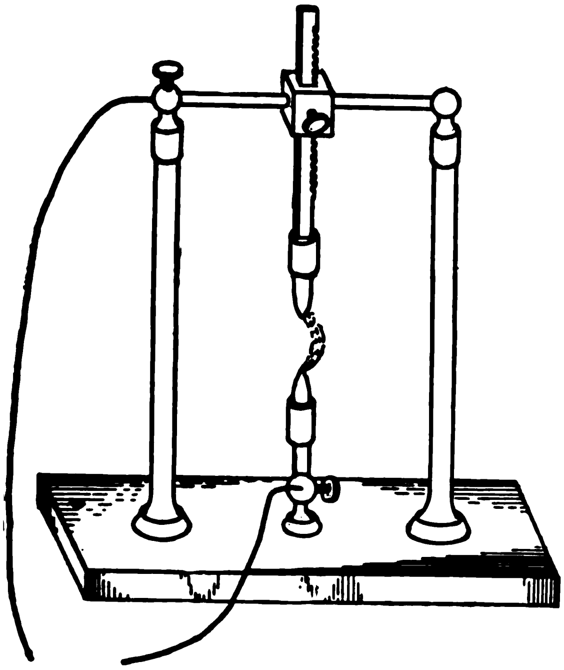

FIG. 2.—OLD FORM OF ARC LIGHT.

The efforts to use it in lighthouses led to the designing and construction of machines on the magneto-electric principle to replace the cumbrous and costly batteries otherwise required. I remember vividly the hours of labor and time necessary to prepare a battery of forty Bunsen cells for use in working a single small arc light for, at most, two or three hours. But I remember far more vividly the suffocating fumes and risk of acid spilling, with accompanying ruin concomitant on the taking down of a partially exhausted battery. Even to work with the arc for an hour or two was, however, adjudged a sufficient compensation for the disadvantages in obtaining the current. All this has, however, been changed, and the past ten or fifteen years has made the arc as a source of illumination one of the indispensables of a progressive community. Instead of the original, little short sticks of wood charcoal used as "points," which were only "points" because it was not expected that the arc would be burned for more than a few minutes without exhausting the battery, there came later on the little hard carbon sticks about two inches long and 3-16 inches square, sawn from hard gas-retort carbon, or from battery plates; and, lastly, came the moulded and forced carbons made from a paste in a powerful press, millions of which are now required every week to keep the lamps at present in use supplied.

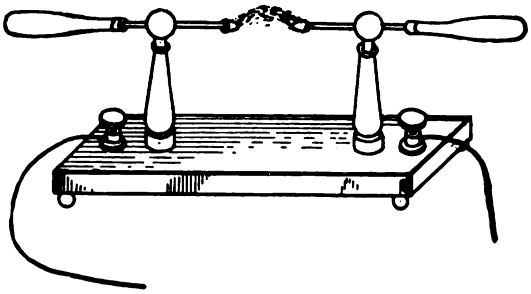

FIG. 3.—OLD FORM OF ARC LIGHT.

The charcoal points of Davy were touched together horizontally after attachment of the wires to the battery and were then separated. The stream of hot flame which followed or joined the points being deflected by air currents took the form of an arch or curve which gave the name to the phenomenon. Even with one carbon directly over the other, the curved form of the stream is the rule when the carbons are widely separated. Davy's original experiment was made with a battery of 2,000 cells, with zinc and copper plates about six inches square, the exciting fluid being very dilute sulphuric and nitric acids.

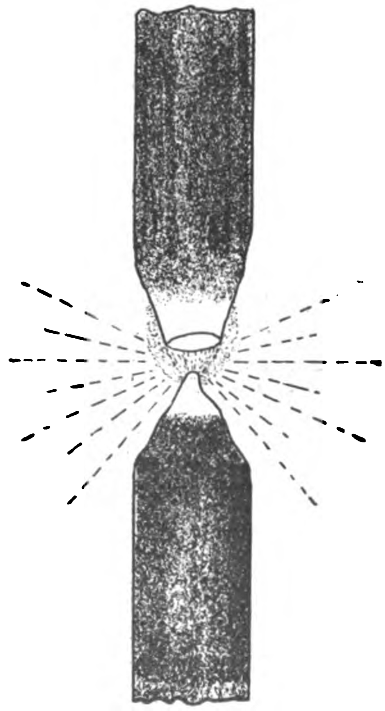

FIG. 4.—THE MODERN ARC LIGHT.

Davy's description is as follows: "When pieces of charcoal about an inch long and one-sixth of an inch in diameter were brought near each other (within the thirtieth or fortieth part of an inch) a bright spark was produced, and more than half the volume of the charcoal became ignited to whiteness; and, by withdrawing the points from each other, a constant discharge took place through the heated air in a space equal at least to four inches, producing a most brilliant ascending arch of light, broad and conical in form in the middle." This was evidently a long, flaming and horizontal arc. I find this form shown in a book published as late as 1846: Davis' Manual of Magnetism. Indeed I know of no more forcible example of the persistency of old ideas than is afforded by the accounts given in the books concerning the nature of the electric arc. The persistence of old cuts is also equally exemplified, even down to the latest publications, giving pictures of the electric arc. The carbons are generally shown crusted over with dense masses of impurities melted into globules and adhering to their sides (Fig. 1). Such figures would not now be recognized as resembling arcs formed with good, pure carbons, such as must be used for commercial results in arc work.

---

[1] Read before the National Electric Light Association, Feb. 18, 1891.

Figs. 2 to 4, inclusive, show the development at least in illustration concerning the electric arc.

Fig. 2 is from Davis' Manual, referred to.

Fig. 3 is one of the figures showing the arc, taken from Ganot's Physics, published in 1863, though the figure is from the 7th edition, 1886. It is virtually the former figure made vertical.

Fig. 4 is a figure of a modern arc.

In regard to the ideas put forward as to the nature of the electric arc there is even a wider divergence than in the figures used for representing it. But these views are remarkable for their general inaccuracy or crudity and evidently have been handed down with modifications. Few of those who have written about the electric arc, at least in the text-books, seem to have had the courage to look at the arc, or they may have seen it "through a glass darkly and not face to face." It would require too many and lengthy quotations to give these various views. In most of them the light of the arc is attributed to intensely heated carbon particles transported by the current from one pole to the other. In most of them the idea of carbon vapor as a possible factor never seems to have arisen. Others attribute the arc to the heated air between the carbons which carries carbon particles, some of which are burned.

The following quotation from a book on electric lighting, published in 1884, is a type of many such accounts:

"In arc lamps, as we have already stated, the resistance which converts the current into heat is that of the heated air between the ends of two carbon rods, from one to the other of which the current passes. The light is produced by the incandescence of the ends of the carbon poles, and of the minute particles of carbon which become detached and float in the heated air between them. The heated air containing the particles of carbon forms what is called the electric arc."

Here the heated air and carbon particles floating therein are definitely stated to form the "electric arc." Nothing is said of carbon vapor having anything to do with it.

Even the statement that the positive carbon burns twice as fast as the negative is very frequently found unqualified in any way whatever. The experience of the lamp trimmer is, I need scarcely say, not in accordance therewith, the fact being that the rate of consumption even in direct current arcs with the same size carbon in both holders varied sometimes quite widely from the proportion stated. However, we shall make better progress if we discard at once the older notions, and, adhering only to that modicum of truth which often accompanies error, supplant the error by the results of our own observations and experiments. My endeavor, will, therefore, be to state as briefly as I can such views of the nature of the electric arc as seem to be borne out by observation during many years, and under greatly varying conditions of its production.

Let an attempt be made to separate any part of a circuit in which the current is maintained by a sufficient E. M. F. or potential, and we find that if the separated ends are moved quickly we get a flash or spark of varying length which becomes a flame of great heating effect if the current be of large rate of flow. If the separation of the two parts of the circuit be made slowly a continuous flame or discharge will take place between the ends if they be not too widely separated or not so widely separated that the potential or pressure of the current is insufficient to force current across the space. With considerable potentials and heavy currents a space of many inches may thus be bridged. Whether the separated ends be of iron, copper, carbon, platinum, zinc or other conductor, the hot discharge is still formed. Therefore while the electric arc is generally spoken of as that flux occurring between *carbon* ends separated, of course it can not be so limited and we frequently, therefore, refer to copper arcs, iron arcs, carbon arcs, to distinguish one from the other. What then is the arc so formed? Is it heated air between the ends separated containing detached particles of the conductor in process of carriage, as was apparently thought for a long time to be the case? No, the arc proper is composed of a stream of vapor arising from the actual boiling or vaporization of the solid or fused ends of the separated conductors. In so far as the surrounding air mixes or combines with this vapor stream it is modified by the presence of oxygen and nitrogen, but the air or any other gas is not essential to be present and is merely incidental to the formation of the true arc stream in air. Indeed it may seem strange to some to speak of vapor of carbon, copper, iron, platinum, etc., but their production is merely a question of temperature in any case. In the electric arc there is a real distillation of the conductors forming it and this accounts for the variation of color and temperature to be found in different arcs. The copper arc evolves a peculiar green light which is exceedingly trying to the eyes as those who have experienced its effects well know. Zinc gives a whitish blue, while the carbon arc proper is purplish in tint. The arcs from various metals give in the spectroscope the characteristic lines of the vapor of each metal.

As a curious incident, showing the presence of the metal vapor in the arc, I may mention the fact that when by accident a person has had a portion of his clothing bathed for an instant in a heavy copper arc caused by a short circuit of heavy current mains there has been found a considerable deposit of copper, enough, in some cases, to give the reddish color of copper to the surface bathed, which, if moistened, turns green by oxidation. It also gives a deep blue to dilute ammonia in which it is washed, thus showing the presence of copper. In like manner these metallic arcs will give a deposit of the metal on cold surfaces which they touch.

It appears to be the positive pole which gives out the vapor stream. With carbon the positive vaporizes steadily and is consumed much faster than the negative. In the use of the arc, however, for lighting we have learned to distinguish between what is called a "short arc" and a "long arc" system. In short arc systems the carbons are burned much nearer together than in the "long arc" systems. Let us suppose the case of two carbons touching each other with a current passing and then that we very slowly separate them, stopping to observe effects. When the contact is light before actual separation, a visible heating of the meeting ends is seen. On attaining a small separation the space between seems filled with hot vapor and we have a short arc where the separation is perhaps not over 2 to 3 one hundredths of an inch. There is also noticed an active transfer of carbon from the flattened end of the positive and a deposition of carbon on the end of the negative carbon. This deposited carbon takes the form of a mushroom end after a time, and breaks off. Meanwhile combustión goes on at both poles and wears away the sides of the positive carbon while the transfer of carbon wears away its tip or crater. The burning also wears away the negative at the sides, while the tip is built up by the mushroom deposit from the arc. But the cutting in of the negative finally severs the mushroom tip and it falls away. Hence both carbons are eventually consumed. To develop a short arc there is required a little over half the potential that is needed for a "long arc," or about 25 volts more or less, and therefore to give out equal heat energy in the arc the current must be double in the short arc over what it would be in the long arc. The short arc is subject to the objection of a continual frying sound emitted and great variations of luminosity; it requires a very dense and hard carbon to conduct the current without great loss, and involves line loss of at least four times the amount with the long arc if equal gauge wires be used.

In fact, while in the past such arcs were common, their number is diminishing, as they are being replaced by the more efficient and completely developed arcs called "long arcs," which are so called to distinguish them from the "short arcs." Returning to our separating carbons we find that as the space of arc is lengthened from the short arc condition, we pass a stage of great flickering and unsteadiness and a fluctuating potential between the carbons, and then reach the stage of production of the long or quiet arc. With ten amperes the separation may now be about 1-16 to 1-10 inch or more. Smaller currents require less separation and larger ones an increased separation. At this stage the arc is quiet, with good pure carbons very steady, and the potential difference remains at about 45 volts, if, of course, the carbon is properly fed to make up for combustion. The perfect arc is really a beautiful phenomenon. While the positive carbon still loses by volatilization from its tip or crater and by combustion from its sides, the negative gains no deposit but wastes at a less rate than the other, and by combustion only. The carbon vapor carried off from the positive is consumed by the oxygen of the air before it can deposit on the negative. Hence the outer zone of flame, which can easily be distinguished from the central zone or arc flux proper, is probably a zone of combustion similar to that existing in ordinary flames. The removal of carbon by vaporization from the positive end, gives rise to the crater or cup which is so prominent a feature of carbon arcs produced by continuous currents. The size or area of the crater is a rough measure of current strength but varies with different qualities of carbon. With very long arcs the crater or hollowed end disappears and the ends become rounded. A well formed crater with the arc or flame confined thereto means usually a steady light, since the chief source of light in an electric arc is from the positive crater which shines like a diminutive sun and represents the hottest part of the arc. The vapor light proper, or flame light, is comparatively very feeble and of a purple quality in air. Hence the arc light is as truly an incandescent source of light as is the incandescent carbon filament, with the difference that to run the latter at the temperature of vaporization or boiling point of carbon, so to speak, means instant destruction, while by the necessities of the case the light obtained from the arc is chiefly that emitted from a surface of carbon at its temperature of boiling, or more correctly of sublimation at atmospheric pressures. This temperature is exceedingly high, and accounts for the well-known superior economy in light production of the arc over all other kinds of lighting. The temperature of the positive carbon crater is so high that the carbon exists there in a soft or plastic condition capable of receiving an impression like putty. I have proved this with very large arcs of 150 to 200 amperes by suddenly forcing the carbons together when the current had been cut off and finding that they would fit each other perfectly, the negative impressing its form on the positive crater.

As an interesting fact in this connection I may state that I have been able to bend carbon sticks of 3-16 to ¼ inch in diameter by passing current through them of sufficient amount to almost vaporize the sticks and cause them to emit an intensity of light approaching that of the arc.

These facts would point to the possible fusion of carbon into liquid carbon at arc temperature under a high pressure of inert gas. No one has as yet seen carbon in this liquid condition, and the electric arc alone has made us acquainted with carbon vapor. One cannot fail to be impressed with the fact that the conveyance of carbon in the arc has a striking resemblance to a plating process where metal is taken up by the bath from the positive plate and deposited on the negative. In the arc the hot vapor stream or flame takes the part of the bath and probably acts by molecular interchanges of carbon atoms in molecules of carbon to cause the transfer which occurs, just as in the plating bath the molecules of the plating compound are polarized and allowed atomic interchange which results in conveyance of metal through the bath.

Another curious fact in relation to the arc is the distribution of potential in it. Dr. J. A. Fleming has recently shown that the difference of potential between the positive carbon and the arc flame is about forty volts, and the few volts which express the difference between the flame and the negative make up the total potential, say, forty-five volts. Hence the real work of the arc is not in the flame; the energy is not used in overcoming flame resistance but chiefly in vaporizing carbon in the positive crater. It is certainly not strange that with forty volts, and, say, ten amperes or 400 watts expended virtually at the crater surface of the positive carbon the temperature and luminous effects should there be so great.

The distribution of potential in the arc just noted was also brought out about the year 1884 in some testimony in an interference in our patent office concerning an arc lamp cut-out which I had invented, and which took advantage of the potential differences between the carbons and the arc flame to cut out the lamp when the arc was too long. It is of course well known that the value of an arc light for general illumination is greatly enhanced by the fact of the distribution of light being mainly in a downward direction in continuous current arcs. This of course follows from the fact of the positive carbon crater being above, such crater being the part from which most of the light comes.

This matter has been quite thoroughly investigated and many diagrams of distribution are to be found in the literature of the subject as published from time to time. They show that with the long arc the maximum intensity of light is from 40° to 60° downward from the horizontal, and that the horizontal intensity is generally much less than one-half as great, while of course the intensity diminishes above the horizontal direction and ultimately becomes zero before reaching the upward vertical direction. In like manner the approach to the downward vertical from the direction of maximum intensity is attended with similar rapid diminution.

The spherical candle power of arc lights would therefore be only a fraction of the rated candle power which is generally taken at the maximum light obtainable in the best direction from the particular arc or kind of arc in question.

For this reason the term 2,000 c. p. arc has little significance as indicating the illuminating power of an arc. It is a convention only and a poor one at that. It is now generally taken to mean an arc with ten amperes and not less than 45 volts potential difference between the carbons, or a 450 watt arc. The quality of the carbons will determine whether the 450 watts will be expended in obtaining the most light or not, or whether that light will have a maximum intensity at one angle or another within certain limits.

When arcs are operated on by alternating currents, the effects mentioned are only partially exhibited, and the phenomena of the crater are of course masked or obliterated on account of reversal of function of the carbons. Unless the alternations are rapid, such arcs are liable to extinction at the zero points of current, particularly when run in a draft of air. A strong draft of air or a displacing magnetic field may of course so disturb an arc as to cause its extinguishment.

In the early years of the growth of arc lighting as a means of illumination, the effects obtained were not of the best. Unsteadiness was the rule, and it required much persistent effort to discover the causes and find the remedy.

The prominent defects were, and, we may add, are still, hissing, sputtering, flaming and general unsteadiness. Hissing or frying comes of course with too short an arc and may be connected with too vigorous vaporization. They may also be due in some cases to a carbon of too coarse a grain. Sputtering may arise from impurities in the carbons, and flaming from too long arcs from impure carbons, or from carbons insufficiently baked and containing unexpelled gases. Running an arc at a length between the long arc condition and the short arc condition may cause great unsteadiness of light. There is, in fact, a critical point in the length below which there is a considerable fall of luminosity and a drop of nearly one-third of potential. As an arc lengthens by combustion of its carbons beginning below this critical point, great unsteadiness will be manifest on arriving at the critical state and a little longer arc brings about a sudden and very marked increase of potential, of illumination and of steadiness.

Any observer may easily detect these conditions without special effort. The earlier carbons used with arc lamps in the United States were both badly conducting, impure, and badly made. Copper coating was a necessity. French or Carré carbons were much better, but were too costly to import. The use of the petroleum carbon or the carbon obtained by the carbonization of the tarry residue left in the distillation of crude oil, made a wonderful difference in the purity of the carbons, and improved machinery gave accuracy of form and cheapness. To one familiar with the former cost of carbons for battery arcs the reductions in cost are very striking: carbons 3-16 inches square cost a number of cents an inch before the year 1878.

Another important matter in relation to carbons is that the size of section or diameter must be proportioned to the current used. Where attempts have been made to prolong the hours of burning of a carbon by enlarging its diameter beyond certain limits, they have resulted in injury to the character and distribution of the light. Large diameters of carbon may burn too blunt to let the light out between them.

Likewise, where attempts have been made to prolong the hours of use by employing a harder or denser carbon than before, it has frequently been found that a sacrifice of light has been incurred, rendering the results much less satisfactory.

One of the chief obstacles to the employment of quite small arcs with currents of three or four amperes is the difficulty of obtaining suitably uniform carbons.

Arcs of even as low as two amperes at 45 volts are easily produced and such small arcs might even have commercial utility if the difficulties in relation to carbons were removed. An arc consuming 90 to 100 watts means of course about 7 or 8 to the electrical horse power.

On the other hand, very large or heavy current arcs are difficult to control. They are apt to be unstable at times, and when they get to hissing, or rather roaring, it is difficult to restore quietness and steady action. The introduction of cored carbons for the positive, has, however, done much to remedy the difficulty, and indeed to render it possible to obtain very uniform results from arcs in general wherever such results are indispensable. The introduction of the central soft core into the carbon seems to locate the arc centrally, hold it from fluttering or shifting its position on the end of the positive; in other words, the core fixes the position of the crater, and so benefits the light.

It follows from the fact that the voltage required to sustain an arc with large or small currents ranges about 45 to 50 volts that the larger the current passing in an arc, the less its electrical resistance. Hence well developed arcs with 4 amperes will have about 11 oms, with ten amperes 4. 5 ohms resistance and with 100 amperes .45 ohms. This fall of resistance with increasing current is easily explained by the broadening or thickening of the arc stream, and the widening of the crater on the positive carbon. This widening of the crater also gives increased illuminating power without increase of temperature. It is probable that the actual crater temperature is as great in the small arcs as in the large ones. In fact, this is implied by the quality of the light remaining the same. Nevertheless the larger the arc the greater the economy or the greater light giving power per unit of energy. This would naturally be expected as the concentration of heat and lessened chances for escape of heat by convection and conduction would conduce to that result.

The fall of resistance with increase of current has an important bearing on the construction of dynamos for arc lighting and the running of lamps on constant potential or incandescent circuits; and will be referred to later on. Attempts have been made at various times to save carbons in arcs by excluding the oxygen of the air which is the cause of their waste or consumption by burning. The gain has not apparently compensated for the disadvantages incurred, particularly as the total exclusion of oxygen means that the carbons become blunt. They would be prevented from pointing themselves or acquiring tapered ends by burning, a condition essential to good working and distribution of light. Even when the arc is formed in a vacuum the carbons, though not burned, are slowly consumed, and carbon deposited as a soot on the sides of the vacuum chamber, an effect consequent upon the vaporized carbon in the arc being carried off and condensed again as soon as the vapor escapes the heat of the arc stream.

In fact, I have found it possible to coat objects on the inside of a bulb with silver or other metals volatilized suddenly by arcs in vacuo, and have obtained in some cases coherent brilliant deposits. The metal is raised in vapor as a metallic arc and distills and condenses on the surfaces near at hand.

Before passing to the consideration of the running of arc lamps in series, or in multiple; and the condition to be fulfilled in each case, we may state that although in ordinary cases an arc is formed by a single pair of electrodes or carbons, and by a single circuit current, compound arcs, or arcs produced by combinations of two or more currents with three or more electrodes, are possible. I am not aware that any others than myself have experimented in this direction. I have, however, produced lights with two positives and one negative, with one positive carbon or crater and two, three or more negatives and with two positives and two negatives. I have caused arcs to cross each other, as when four carbons are used, pointing towards a centre, the two pairs opposite being respectively connected with different circuits. In this way direct arcs have been, as it were, mixed with alternating arcs and a curious compound effect produced by crossing two arcs made with two alternating currents the waves of which are displaced in phase. Without going fully into these experiments I will present figures showing two good examples. Fig. 5 is formed by two currents sent into a positive P and dividing, after passing the crater, into two streams going to the two negatives. In this case the positive crater is fully exposed horizontally and gives a most intense light in a direction forward. Such an arc is well adapted for projection by mirrors or lenses.

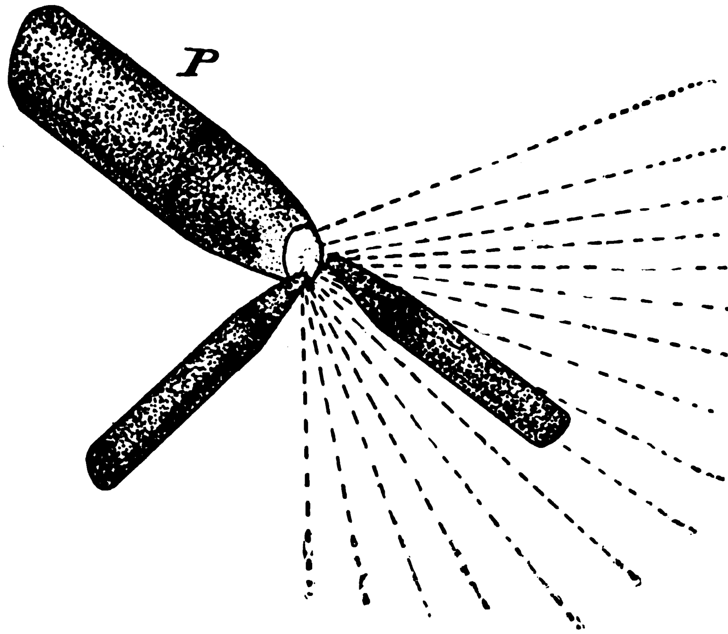

Fig. 5.—Arc Formed Between One Positive and Two Negative Carbons.

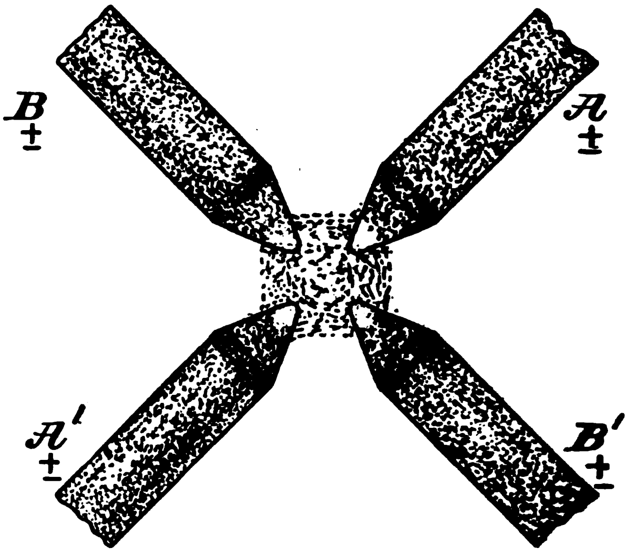

Fig. 6.—Arc Formed By Crossing Two Alternating Currents Out of Phase.

Fig. 6 shows the arc formed by crossing two alternating currents out of phase. In this case there is at successive times an exchange of current between all four carbons in varying directions so that the arc flame becomes, as it were, a ball or disc of very hot flame supported by the four carbons. These experiments have not been fully described as yet, owing to the lack of time, but they show very well that even when we have fully studied the single, simple arc, we will not then have exhausted the subject as these compound arcs may be varied in character to a great extent and present new effects.

In regard to that portion of our subject which concerns the use of the electric arc for lighting, it is true that there is a wide field before us. I cannot hope to do more in this paper than to outline, in addition to the considerations already alluded to, some of the other prominent features of the subject. It is well known that by far the larger proportion of electric arc lights in operation is run on circuits of constant current, the lights being in series.

If arc lamps be connected in parallel, as on low potential incandescent mains, special devices are required to keep the current supplied to each lamp at the right amount.

It may appear at first to one who has not had occasion to closely study these matters that, given a constant potential circuit of fifty volts, arc lamps requiring fifty volts could be connected in multiple or parallel without difficulty. The fact is, however, that the condition of electric arcs being supplied with a constant potential involves a theoretical impossibility. Theoretically, such an arc would take an infinite current and energy. Practically, the current in an arc with constant potential becomes very heavy and if the carbons be separated to cut the current down, as by a lamp magnet mechanism, a condition of fluctuation and instability results. This is a direct consequence of the fact before stated that the resistance of an arc is not like a wire resistance but falls with increase of current, and vice versa. For stability the resistance should not be dependent wholly on the current passing. To remedy the instability a resistance known as a "choking coil" or "sluggishing coil" is inserted in the arc branch and the potential raised, say, to 65 or 70 volts. Under these conditions, that is with a resistance taking up 15 to 20 volts, in series with the arc, it may be run in multiple with incandescent lamps or with other arcs. There is, however, a waste of energy equal to the product of the current strength by the loss of potential, 15 or 20 volts, in the resistance. A great deal of useless experimenting has been, and probably is yet, carried on with the vain endeavor of getting rid of the resistance or choking coil in this case, but the difficulty is inherent in the nature of the arc, the relation of resistance to current giving rise to instability of current in the arc.

Similarly, not all dynamos, even if of sufficient potential, will run arc lamps in series. Arc machines require special properties or the current will be unstable and the light will fluctuate or "surge" as we sometimes call it, possibly to an extent amounting to extinction and relightings occurring at short periods apart. This action, like the other, is dependent on the relation of current and resistance as inherent in electric arcs, and the series of lights would in each case require dead resistance up to a certain amount in circuit to render the current stable. Then, whether a series be operated or a single arc be operated, either a dead resistance must exist in circuit or the current supplying apparatus must have special properties. The arcs produced from batteries were stable because the resistance of the battery itself was sufficient to ensure this. Arcs are not stable as fed from accumulators of very low internal resistance unless the arc is one of enormous current.

Briefly, the property required to be possessed by an arc dynamo is that as its current rises above the normal the electromotive force must fall, and as the current dimishes to a little below the normal the electromotive force of the dynamo must rise. It is not sufficient to secure this changing E. M. F. by regulators, as they are generally behind time for causing stability of current, however well they may operate to regulate for varying numbers of arcs in the series to be supplied.

The properties of dynamos are sometimes expressed by what are called "characteristics," or "characteristic curves," obtained for example by laying off vertically, or on the ordinates, the electromotive forces corresponding to varying currents given out by a machine, which currents are laid off horizontally, or as abscissas. In arc machines the curve so produced is convex upward and droops at its outer end *b*, Fig. 7. Assuming normal current at 10 amperes and an E. M. F. of 500 volts, at 11 amperes the E. M. F. may have fallen to 420 volts and at 9 amperes risen to 530. We would then be working on the "droop" *a* to *b* of the curve when at 10 amperes; and such a machine is stable as to current for running arc lamps. There appears to be required not merely a droop in the curve, for securing stability, but more than a certain amount of rate of droop or dip. If the line could be made to droop or dip vertically after passing the normal current the machine would regulate without a regulator or be a constant current automatic machine.

In what respect then do arc dynamos differ from others to produce this relation of droop in the characteristic curve? Without doubt the effect is mostly due to the reactionary effects of the armature on the field, which effects in arc machines are made greater than in others, and the field magnets meanwhile are frequently saturated magnets, so-called, and not greatly sensitive to the current in their coils. The armature of an arc machine is indeed so powerful an electro-magnet that it is able to control the magnetism of a portion of the field in which it turns. A sort of balance of magnetic forces is established at certain portions of the field which on an increase of current in the armature produces polarity opposing the field polarity at the portions mentioned, such as will cut off some of the lines of magnetism from entering the armature core and so lower the electromotive force; while a lessened current in the armature will weaken its polar portions and an increased number of lines will enter the armature core from the field and so increase the electromotive force at the brushes of the commutator. In Fig. 8 the portions at K K are those at which the balance or conflict of opposing poles of armature and field magnet exist, namely, at those portions near the diameter of commutator or position of the brushes on the commutator.

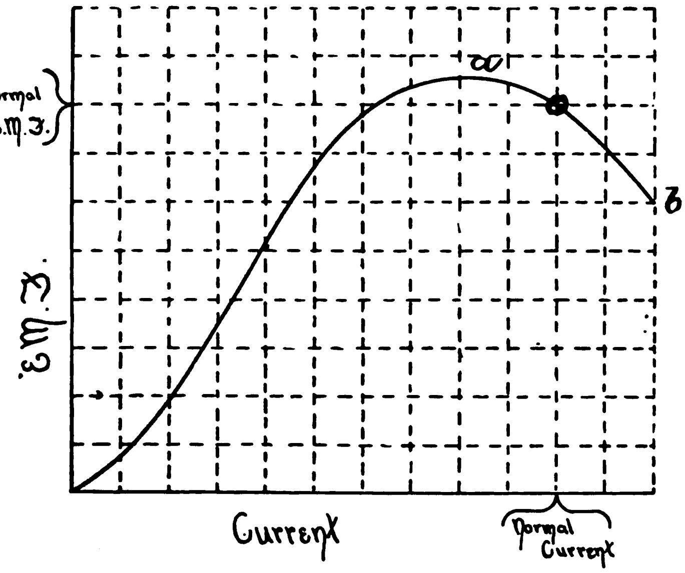

Fig. 7.—Characteristic of Arc Light Dynamo.

Could the droop or fall in the characteristic curve be made a vertical as stated before, then we should have a self-regulating machine not needing a regulator to preserve a constant current under all loads. This condition is more easily arrived at in alternating machines, one of the first, if not the very first, example of which is found in the Chertemps-Dandeu machine which was tested by Robert Sabine, as described in Dredge's "Electric Illumination," vol. 2, 1885. This machine had the remarkable property of permitting ten arc lamps to be cut out or put into its circuit in series in any way without causing a variation in current strength of more than ten per cent. The interactions occurring between the armature and field accounted for this regulating property. In these cases the armature currents react upon the field with a force producing at times a balancing of magnetism between the two. The distortive power of the armature upon the field is made very great, which amounts to the same thing.

In the recent alternating machine for constant current brought out by Mr. Wm. Stanley we have an excellent example of the application of similar principles of construction, together with the difference that the arc lights which were fed direct in series from the Chertemps-Dandeu machine, are run from transformers with the primary coils in series in the Stanley apparatus.

The relation of current to constancy is, however, in continuous current dynamos for arc lighting, generally effected by regulators as they are called, which so alter the dynamo on a slight increase or decrease of current as to raise or lower its electromotive force according to the resistance in circuit, or speed.

In one form of regulator the effect is obtained by changing the field magnet strength by automatic mechanism, weakening the field when lamps are cut out and strengthening it when lamps are added to the circuit. Another means of regulation is the rotation of the commutator or brushes so as to take current from positions corresponding to increased or decreased electromotive force in such a way that the current obtained is constant. The former method first appeared in the Brush arc apparatus and the automatic commutator brush movement in the Thomson-Houston machines. The latter method renders the machine completely automatic under variations of load while in the former there still is required a manual spark adjustment of the brushes as the field magnet is altered in force under different loads. The two methods were subsequently combined by the writer in conjunction with Mr. E. W. Rice, Jr., in such a way that the necessary brush adjustments were made automatically at the same time with the variations of the field under different loads. This combined method has been used for some time past in the Excelsior machines constructed under the patents and designs of Mr. Hochhausen, whose name is so well known in connection with arc lighting and plating and other electric apparatus in this country. On account of the fact that with the addition of arc lights in a series a higher and higher potential difference is required at the terminals of the dynamo, it becomes a question how far this increase may properly be carried. It is not unusual in the present practice to run from fifty to sixty lights in a series, each demanding from forty-five to fifty volts, or a total of, say, three thousand volts. In going beyond this amount the difficulties of insulation are greatly increased, as well as the dangers of high potentials, while the consequent risk of breakdowns resulting from failure of insulation or leakage are often sufficient to offset any saving of wire conductor that might be obtained by running more lights in series. Instances have occurred in which with ordinary wiring and precautions, 120 to 150 arcs have been run for days together, but such a practice is to be condemned as involving hazard of all kinds.

It has been supposed by some electricians that there existed a peculiar fitness for arc lighting in series in dynamos of the open coil type, such as the Brush or Thomson-Houston, over those of the closed coil types, such as the Gramme or Siemens forms. Whilst, personally, I have never been prepared to admit this peculiar fitness, constructors of machines of the closed coil types have certainly succeeded in removing any doubts on that score. Mr. J. J. Wood has, in building his form of Gramme machine up to the highest capacities for series work, taken a leading position in this respect. In fact the simplicity of the commutator and the ease of insulation of machines of the open coil type undoubtedly rendered them more capable of retaining insulation at high potentials than the early commutators with numerous segments used on Gramme and Siemens machines, as such commutators were at first constructed. Likewise, improved methods of insulation and winding have gone far to put both types of machine far in advance of what they were formerly. While on this subject of arc machines it may be well to say a few words as to the action of flashing which can occur in all machines of high potential under certain conditions. In the first place the term flashing, as here used, is not intended to refer to sparking at the commutator, but rather to a flash or continued spark carried over during revolution of the armature from one brush towards the other, either all around the commutator or part way only. This action occurs when any two successive segments in the commutator continue their discharge one towards the other over the insulating space between them during a considerable part of the revolution. An arc forms in the slots or between segments and moves with them. This action, while not very damaging where the segments are massive and insulated with air spaces, is more serious with insulation filling between the segments, as it is apt to cause a burning out and either short circuits the armature coil sections by connecting the segments, or seriously roughens the edges of the segments and the face of the commutator.

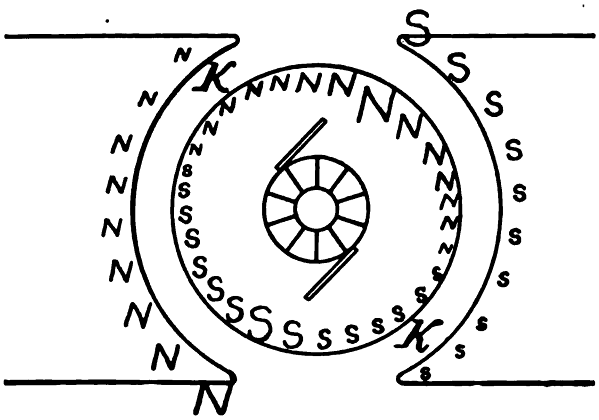

Fig. 8.—Distribution of Magnetism Between Armature and Field.

Bad setting of brushes may cause both sparking as well as flashing; and dirt, in some cases, or too much oil, may cause it.

Slipping of belts or sudden fluctuations of speed may also provoke it. Or a machine, overloaded, may flash by an opening of the circuit due to too many lamps, the electromotive force required for which number the machine can not maintain. The presence in a circuit of one or more lamps which do not feed properly may cause momentary cessations of current and flashing to occur, especially when the machine is carrying its full load. With all arc circuits there should, of course, be a surplusage of capacity in the dynamo, *i. e.*, the machine should not be run to the limit of its electromotive force. It has become customary with the best makers to so rate this capacity that there will always be a margin of excess to meet contingencies. The line resistance may, of course, be, in the case of long circuits, such as to cut down to a considerable extent the working capacity or number of lamps in series which can be run from the dynamo, and due allowance should always be made for this resistance in estimating the true capacity. Instances are not uncommon in which by improving the contacts of switches, hangers, joints, etc., a gain of two or three lamps may be made in circuits of fifty or more lamps in series. An improvement in the insulation of a line will often have a similar effect in adding to the apparent capacity.

I had intended at the outset of this paper to discuss in a general way the question of the different types or classes of lamps used for arc lighting. It is a department of the subject which is of considerable importance, but I find that the paper has become too long already, and for the present I will simply allude to one or two general features. Concerning the manner of feeding the carbons the mechanisms in use may roughly be divided into clutch and gear mechanisms. Among clutch mechanisms we find certain well known forms while the gear mechanisms best known are of the escapement order. Both types have undergone many modifications, and combinations of the two exist.

Whether one or other type is to be selected will depend largely on the conditions of use, assuming both to be equally well constructed and kept clean. Into these questions, however, we can not now enter.

Arc lamps may also be divided according to the way in which the magnet system acts to control the feed of the carbon. Before arc lamps were run in series it was sufficient to have the controling magnet in the main circuit and this was the case in almost all the older forms of lamps. The Lacassagne and Thiers lamp of 1856 was a notable exception in that the control of the feed was differential, or dependent on the difference of power between a main circuit coil and a high resistance shunt circuit around the arc.

I have, in fact, made an exact reproduction of the Lacassagne and Thiers lamp according to their patent specification and have found that its action is perfect when used in series with other lamps, except that it requires to be helped to separate its carbons. If the carbons are quite pointed at the start even this is unnecessary, as the points soon heat and burn away and form the arc. The feeding depends on the flow of mercury through a small valve which is adjusted by the differential magnet system, and the feeding is so continuous and imperceptible that the arc is beautifully steady and constant in length.

At the present time the differential lamp magnet system is of several kinds, according to the relative disposition of the main and shunt coils.

In the commercial Brush arc lamp they are disposed one over the other on the same axis and affecting the same magnetic cores. The only objection to this disposition, which has the advantage of simplicity, is that the shunt circuit can never act positively to feed the carbons or release the clutch or gear, but can only weaken the effect of the main coil or overpower its lifting or separating action on the carbons.

Other forms of differential lamp embody two circuits acting on separate magnets pulling in opposite directions, the main circuit to separate the carbons and the shunt to feed them. In this case the action of the shunt is more definite and positive, as it is not limited simply to overcoming the force of the direct or main magnet.

A third arrangement involves the application of the repulsive action of the two coils, as when the direct coil is wound on a fixed magnet, and the other, or shunt, upon the feed controlling armature therefor and tending to cause repulsion of the armature from the main magnet. This arrangement is both simple and positive in its action.

The differential types of lamp act well when the circuit current is kept constant and require readjustment generally for each change of current strength by which they may be operated. Hence, if a portion of a line be leaky the lights are apt to burn badly owing to diminished current, while the dynamo may be furnishing full current. Of course such a line ought to be condemned and its insulation improved. Nevertheless I have frequently seen lights suffer from leakage on extended circuits in cities, especially in very wet weather. This is a state of things which the line superintendent can do more than any one else to correct, by attending to the correct disposition of the wiring, and its character as regards leaks.

The type of arc lamp in which the shunt magnet alone controls the feed of the carbons is not sensitive to slight variations of ent but maintains a full quiet arc with the current it gets. This is because the main current is not concerned in the feeding action, but the action is solely dependent on the potential difference of the carbons. Hence its behavior is on the whole more uniform than the differential type, and within limits it does not require re-adjustment for different current strengths.

This principle has been extensively introduced in the Thomson-Rice lamp of the Thomson-Houston Company. In this lamp the carbons are separate at the start and are brought together on the first passage of the current, after which they separate solely under the influence of the shunt circuit magnet and the feed is likewise controlled thereby. The carbons in these lamps are not so apt to slide by, or alongside, each other by jarring when no current is on the lamp, as may occur, particularly with careless trimming, in those lamps in which the full weight of the upper holder and carbon must be borne by the under carbon when the lamp is not lighted.

Arc lamps have been made with many variations in the magnetic arrangements controlling the carbons, a brief statement of some of which is as follows: Carbons lifted or separated by direct or main magnet; shunt magnet acting on a variable resistance to cut out the main magnet in feeding. Carbons lifted by main magnet as before and shunt acting to put the main magnet (made movable) into position for feeding.

Carbons separated by main magnet armature; shunt circuit magnet acting to divert or shunt the magnetism of the main magnet from its armature.

Carbons separated by main magnet and shunt acting to free the carbon holder independently of the support given by the main magnet.

Carbon separated by a spring and allowed to act by the main magnet lifting a weight which otherwise holds the spring from acting; shunt magnet acts against the spring to feed and regulate length of arc.

One carbon, generally the lower, separated by main magnet, while the other holder is released for feeding only, such feeding being under the control either of a differential system or a shunt magnet only.

Carbons separated by main magnet which lifts the shunt and its armature together, while the shunt magnet armature, acting on the feeding mechanism, controls the arc and feed of the carbons.

Carbon feeding mechanism independently attached to main magnet armature and to shunt armature, so as to receive opposite movements of separation and feed from each respectively.

Carbons separated by a feeding mechanism moved by the main magnet and fed by a further movement of said mechanism causing release or return of same under the accumulated force of both shunt and main magnets acting in the same direction.

Differential clock gear for separation and feed of carbons under control of the regulating magnet system either simple or differential. Some of the older clock-work lamps embodied this principle.

Carbons controlled by armature of a small electric motor under control of a differential field which turns the armature in one direction for separating, and in the other, or reversed, direction for feeding the carbons. Tchikoleff's early lamp was of this type.

Carbons controlled by a motor running at a certain speed when the arc is of normal length and varying in speed when the arc is too short or too long, combined with a centrifugal governor on the shaft of the motor acting on variations of speed to gear motor shaft to screw carbons together or apart, as needed, to maintain the normal arc. This mechanism has been applied by me to to large arc lamps such as naval search lights and has the advantage of great positiveness and an ability to handle heavy mechanism.

There are also a considerable number of modifications from these principles stated which cannot be referred to here.

Another excellent mechanism and one of the most powerful and positive in feeding the carbon, embodies a main magnet separating the carbons and striking the arc and an intermittently acting shunt magnet for working a pawl which, by a suitable gearing, forces the feeding action or approach of the carbons as required. I have used an endless screw gearing with the pawl acting on a ratchet wheel to turn the screw, the worm wheel being on a shaft carrying a pinion meshing into a rack on the carbon rod. The worm wheel gearing is lifted by the main magnet to strike the arc, and the shunt magnet in operating its pawl breaks its own circuit and repeats its feeding action as often as may be necessary.

It is interesting to note in this connection that I have built such lamps in which each feeding movement of the carbon is not over one-five-thousandth of an inch and that if the upper carbon rod is held in a vise the mechanism will lift the whole lamp of about twenty pounds weight in feeding, so positive is the action. At the same time the length of the arc is maintained constant at all times. With so slight and yet positive a feeding action the feed takes place almost continuously.

In the foregoing brief review many matters have been simply touched upon which might readily have been singly expanded into a paper as long as the present one. Material enough now certainly exists and could be collected, for making a good technical work dealing with the science and practice of arc lighting.

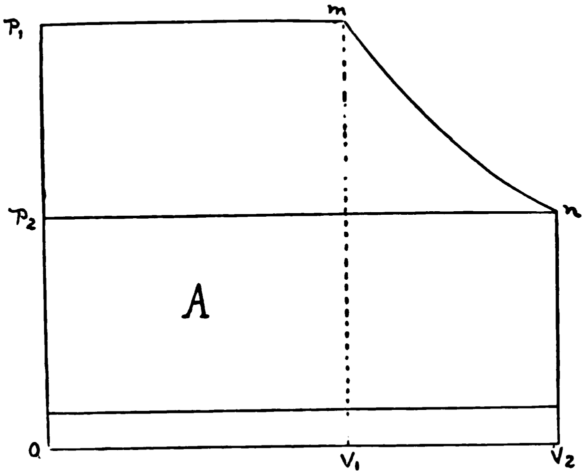
My purpose will have been fulfilled if I have succeeded in the present paper in adding some things of interest and instruction concerning this general subject from the standpoint of one who has constructed very many forms of apparatus for arc work, and who has had a continuous and growing experience with such work from its beginnings up to the present great commercial expansion.

DISTRIBUTION OF STEAM FROM CENTRAL STATIONS.[1]

BY F. H. PRENTISS.

WHAT has the distribution of steam from a central station to do with electric lighting? This question can be answered much after the Yankee fashion of asking another. What has coal-tar, ammonia, aniline dyes to do with making gas? These articles are bye-products in the manufacture, which were once thrown away as useless, but which have now a value hardly second to that of the gas itself. Is it not true that the exhaust steam of electric light engines is a bye-product in the making of light, and for heating purposes has a value scarcely less than the electric light itself? Since in a steam engine the amount of heat converted into work is relatively very small, the value of the bye-product or the exhaust steam is too large to suffer neglect. It is only a question of finding a market for it, and obviously this can only be done by a system of distribution from a central station. Will it pay to market this product? The answer to this question depends upon many complications and varied circumstances which in no two plants would be found alike.

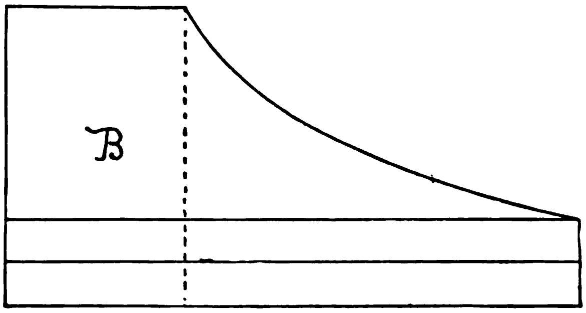
The history of commercial electric lighting covers hardly a decade. The same is true of the sale of steam from underground pipes radiating from a central station. In both of these enterprises, frequent failures have been met with and many lessons learnt. I believe it is a fact, however, that all present existing steam companies more than pay expenses. A few have paid dividends while many have been obliged to re-invest their earnings in improvements or remedying defects in original construction. The very few absolute failures have been due to faulty design, or defective engineering at the start. In the city of New York, two companies were started less than ten years ago, one of which, owing to faulty design, failed and gave up business; the other, known as the N. Y. Steam Co., is supplying steam for power and heating to nearly seven hundred consumers, and sells the product annually of more than 100,000 tons of coal burned under boilers aggregating nearly 20,000 h. p.



CYCLE OF CHANGES OF STEAM, CASE NO. 3.

In its distribution of steam through underground pipes the company has had many obstacles to contend with, the chief trouble having been the securing of absolutely tight joints. This difficulty has been completely removed by the method employed during the last four or five years, as is well attested by the network of pipes on Madison avenue and the adjoining streets between 53rd and 70th streets, where nearly three miles of pipe are in perfect operating condition and practically without a leak. The engineering difficulties which in an enterprise of this kind would strike one as more difficult to provide for, namely, the expansion of the pipe and the losses due to radiation, were most perfectly provided for at the start, and therefore, with the improvements which have been attained through practical experience of nearly ten years, the system has been brought to a state of perfection where in new work but little more can be desired. The pioneer work has been done and the electric lighting companies are therefore in a position to reap the advantage of the experience gained and to begin their work where the steam companies have left off, and can therefore feel certain in seeking for a market for their bye-product (their exhaust steam), to meet with no mechanical difficulties of construction.

The joining of two enterprises together, such as electric lighting and the distribution of steam from central stations, has both its advantages and its defects, and we must weigh one against the other. The electric light station is already in possession of its boiler house equipment, and for this reason has much less to charge up to the construction expense of steam distribution than a steam company, since its boilers are available for supplying steam directly to the street mains, when light is not called for or when the engine load is at a minimum, and can furthermore by proper adaptation deliver the exhaust steam from the engine into the street mains, and for the purpose of heating recover the larger portion of the original heat value of the steam. Again, in a combined plant the general expenses of management, superintendence and so forth, need not greatly exceed the cost for the same items in a single plant alone. An obvious disadvantage is the increased back pressure put upon the engines. I am assuming, of course, that the engines are of a non-condensing type. The prejudicial effect of this back pressure is a subject which will well repay a little study.



CYCLE OF CHANGES OF STEAM, CASE NO. 2.

Thirty pounds of water per h. p. per hour is the recognized standard of boiler capacity and is also a fair statement of the amount used by an engine of fair size exhausting into the atmosphere. A portion of the work of such an engine is spent in overcoming the atmospheric pressure of 15 lbs. per square inch, and when, therefore, in addition to the pressure of the atmosphere, an increase of back pressure is incurred, the useful work of such an engine is diminished by a corresponding amount. If this increase of back pressure is only that required for circulation of the steam for heating purposes, the increased consumption per useful h. p. per hour will not be greatly augmented in consequence, provided the pipes are sufficiently large and properly run.

The heating of residences by steam supplied from our 58th street station is often effected with steam at a pressure of one or two pounds. And it is well known that there are several systems in use where exhaust steam is applied for heating in a manner so as to make it possible to produce a vacuum in the heating coils. The back pressure of the exhaust, therefore, in a system where the engines discharge into street distributing mains, depends almost solely upon the size of the mains and the quantity of steam carried. A loss of pressure of 10 pounds in a half-mile of pipe provides a carrying capacity reasonably in accordance with the cost of the pipe. Of course if this difference of pressure exceeds 10 lbs., the cost of transportation becomes relatively less, while the loss at the engine becomes greater, and vice versa, in case the loss of heat producing flow of steam is less than 10 lbs. This, like many other details, must be determined upon in each particular case. In order to illustrate this point I will present some calculations based upon a back pressure of 17 lbs., absolute (about 2.3 pounds ordinary gauge) with an initial pressure of 92 lbs. absolute (or about 77.8 lbs. ordinary gauge pressure). We will call this Case No. 1.

For Case No. 2, let us take the back pressure at 30 lbs. absolute (about 15.3 gauge) and the initial pressure at 105 lbs. absolute (or about 90.3 lbs. ordinary gauge).

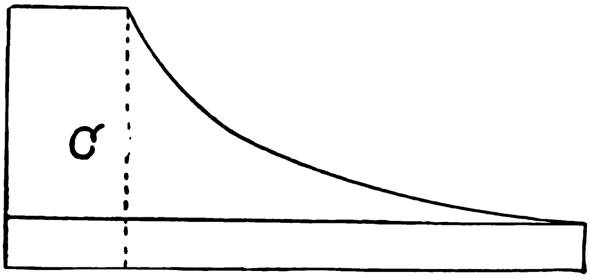
In Case No. 3, let the back pressure be 105 lbs. absolute, and initial pressure 180 lbs. absolute. The last case is interesting, since it called for a theoretical consumption of steam per indicated h. p. in an engine with an initial gauge pressure of about 165 lbs. and a back pressure of about 90 lbs. gauge. The diagram marked *A* shows the cycle of changes of steam used under the above conditions—omitting the practical considerations of wire-drawing, compression, early release and so forth, which are the interesting characteristics of an indicator diagram. The tremendous amount of unutilized work due to the excessive back pressure is clearly shown by the area of the rectangle P_2 V_2. In this diagram P_1 and P_2 are laid off as ordinates to represent the initial and back pressure, while V_1 and V_2 are laid off as abscissæ to represent the volume of 1 lb. of steam before and after expansion. The expansion curve *mn* is supposed to follow the law $P V^{\frac{17}{16}}$ = constant. The diagrams *B* and *C* represent Cases 2 and 1.

---

[1] Read before the National Electric Light Association, Feb. 17, 1891.

At pressure P_1 (180 lbs. absolute) Fig. *A*, the volume V_1 of 1 lb. of saturated steam is 2.49 cub. ft., and at pressure P_2 (105 lbs. absolute) the volume V_2 of 1 lb. of saturated steam is 4.14 cub. ft. Neglecting all cylinder losses due to condensation, leakage, clearance, etc., and supposing the expansion curve to conform to the formula $P V^{\frac{17}{16}}$ = constant, we have for the total work in foot pounds of 1 lb. of steam:

$P_1 V_1 \times 16 (P_1 V_1 - P_2 V_2) = 95645$ ft. lbs. Deducting the work of overcoming the back pressure ($P_2 V_2 = 62597$), we obtain, $95645 - 62597 = 33048$ indicated ft. lbs., and as 1,980,000 ft. lbs. per hour is equivalent to one horse power, it is evident that an engine working under conditions above-named would require $\frac{1980000}{33048} = 60$ lbs. of water per h. p. per hour.



Cycle of Changes of Steam, Case No. 1.

In a similar manner it may be shown that between the limits of pressure, 90 lbs. (105 lbs. absolute) and 15 lbs. (30 lbs. absolute), there would be required 26 lbs. per indicated h. p. per hour. This covers the case of an engine exhausting into low-pressure street-mains.

An engine exhausting into the atmosphere with 2 lbs. back pressure (17 lbs. absolute) and receiving steam at 77 lbs. (92 lbs. absolute) would require 19.7 lbs. of water per h. p. per hour.

In actual practice the losses due to clearance, wire-drawing, incomplete expansion, cylinder condensation, etc., would have to be added to the amounts above given.

If in the last case (*C*) we add 10 lbs., making about 30 lbs. per h. p. per hour, we shall have an average practical result as obtained from automatic single cylinder engines of fair size.

The great loss due to cylinder condensation is largely dependent upon the difference of temperature between that of the steam at admission and that at exhaust. In cases *A*, *B* and *C*, this difference is respectively 42°, 81°, and 102°, and hence, with the same size cylinders in each case, it is quite sufficient to make the same allowance of not more than 10 lbs. additional for *B* and *C*, making for *B*, about 57 lbs. per h. p. per hour, and for *C*, 70 lbs. per h. p. per hour.

Now, in an engine operated in such a manner there would be, during expansion, a loss of heat due to conversion of the internal energy of the steam into work amounting to $\frac{16 (P_1 V_1 - P_2 V_2)}{772}$ $\frac{31104}{772} = 40.3$ thermal units per pound of steam, which would produce a condensation amounting to 3.3 per cent. The total thermal units (above 32° F.) per pound of steam at 105 lbs. (absolute) pressure is 1182.4 or $(1182.4 - 187) = 1000.4$ above the temperature of the feed water (212° Fahr.) Hence the available heat in the exhaust would be $1001.1 \times .687 = 968.35$.

Before entering the cylinder, however, the steam at 180 lbs. (absolute) contained (1195—181)—1014 thermal units per pound above the temperature (212° Fahr.) to the feed water. Hence the total loss due to conversion of heat into work is $1 - \frac{968.35}{1014} = .045 =$ 4½ per cent.

In addition to this loss in the cylinder of the engine we must consider a further loss at the boilers owing to the fact, that by raising the pressure we have increased the temperature of the steam 42°.

Now assuming that the increase of the temperature of the escaping gases amounts to 42° (and it certainly can be no greater) and allowing 24 lbs. of air per pound of coal, we have $42 \times 24 \times .238 = 240$ thermal units lost per pound of coal burned.

Now assuming that one pound of coal evaporates at 105 lbs. pressure (absolute) 8 pounds of water which is equal to $(1182.4 - 181) \times 8 = 8011$ thermal units, the loss at the boilers therefore may amount to $\frac{240}{8011}$ = about 3 per cent. Adding this to the previous loss of 4½ per cent. we obtain a total loss of 7.5 per cent. But this loss must be figured on a basis of 70 pounds of water per h. p. per hour and hence when computed at 30 pounds becomes $\frac{70}{7.5 \times 30}$ = 17.5 per cent.

Therefore we have practically obtained our work in the high pressure electric light engines at the rate of five and a quarter pounds per indicated h. p. per hr., the re-evaporation during exhaust, together with the unbalanced motion of the steam due to eddies, wire-drawing, etc., appearing again as steam or useful heat in the street mains.

This is clearly an extreme case, but for this reason it better serves as an illustration. The percentage of steam condensed to water through the conversion of heat into work during expansion would be greater in Cases 1 and 2, but in these cases it would hardly be necessary to consider any possible extra loss at the boiler.

Diagram D is the representation of an indicator card taken from an engine operating under conditions of excessive back pressure similar to case No. 3, diagram A. The back pressure in this instance was about 55 lbs. above atmosphere and the initial pressure about 130. The engine was an automatic cut-off type taken from the salesroom of a well-known engine builder, having been built for ordinary duty and not especially designed or altered for work of this unusual character. The engine was directly belted to a 750 light A. C. Westinghouse dynamo, which supplied current to about 600 incandescent lamps in the Lenox Lyceum, 59th street and Madison avenue.

The building was wired throughout on the Edison three-wire plan and the converters were arranged two in series with a middle wire to suit these conditions. The plant was supplied with electric meters and the various station instruments, and represented therefore, on a small scale, a central electric light station. The exhaust pipe of this engine was directly connected with our street mains, where an average steam pressure of about 55 lbs. was always maintained. The steam from the street mains was used in part for operating elevators in apartment houses and for running engines, and in part for heating. If we follow the steam in its course through the electric light engine, thence through the elevator, engines and pumps, and other engines along the line of the underground steam mains, and thence to the radiators where condensation takes place, it will be evident that an economy is attained similar to that in a compound condensing engine, the electric light engines playing the part of the high pressure cylinder, the other engines playing the part of the low pressure cylinder, and the radiators taking the place of the condenser.

This engine was operated under these conditions three or four evenings a week for about a year, affording a perfectly steady and satisfactory light for incandescent lamps. The running of the engine was not attended with any special difficulties and gave no more care and occasioned no more trouble than if exhausting into the atmosphere. On several occasions the exhaust of the engine was shut off from the street mains and turned into the atmosphere, the initial pressure being reduced at the same time to correspond. At other times the reverse of this change was effected and the exhaust turned from the atmosphere into the street mains without in either case producing a noteworthy fluctuation in the light from the incandescent lamps.

The gross revenue to be derived from the sale of steam for the heating of buildings may be estimated at from $2.50 to $5.00 per thousand cubic feet of space heated per season. The amount of heating to be obtained per mile of street mains will evidently vary very much according to locality, and in the dozen or more district steam companies, it is interesting to note what this variation is. In the smaller towns where systems of underground steam distribution exist, the space heated seems to vary from 1 million to 2 million cubic feet per mile of street main, and in the case of a larger city reaches 5 millions, and in the city of New York exceeds 15 millions.

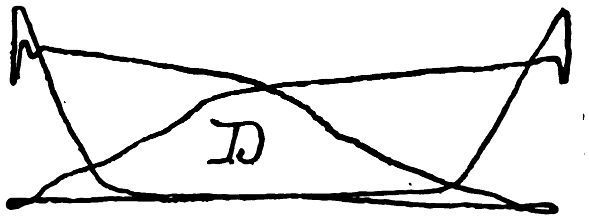


Diagram of Engine Working Under Excessive Back Pressure.

The cost of plant (which in these figures includes boiler house and boilers), varies from $20,000 to $30,000 per mile, and in one instance reaches $50,000.

In New York city the cost very much exceeds these figures, owing in part to the difficulties encountered and in part to the fact that the street mains were laid with a view to supplying steam for power. In the N. Y. plant, the pressure of steam in street mains is above 80 lbs. and furnishes a supply to over 500 engines and requires for this purpose in the summer time about 250 tons of coal daily, and, including heating, reaches 500 tons daily in the winter. The cost of plant is greater in cases where steam is furnished for power as well as for heating. The actual cost of a district steam plant, where the business is confined to heating alone, seems to vary from $10.00 to $20.00 per 1,000 cubic feet of space heated. Here again this cost includes boiler house and boilers.

In order to make it clear beyond dispute that the business of a district steam company can be added to that of an electric lighting company without prejudice to the latter, two points only need be established. First, the possibility of utilizing the exhaust of electric light engines without detriment to the light, and without introducing any serious complications or expense in the management of the station. Second, the certainty of an extra revenue, the net profits of which will equal or exceed the profits from the lighting plant for equal amounts of money invested. I have already touched upon both of these points and need, I think, only refer to the practical working of the combined system at the 58th street station of the New York Steam Company, where the back pressure of the engine was 55 lbs. (with no inconvenience and with no extra expense, save an almost indeterminate increased consumption of fuel) to prove that with a back pressure of only 15 lbs. a practical mechanical success is assured. Of course, to get the same power from the engines, it would be necessary, unless previously running with a light load, to increase the initial pressure 15 lbs., or to the same extent that the back pressure is increased. The effect of this, as I have shown, will be merely to pass a little more steam through the engine per h. p. which ordinarily would be a bad practice and a waste of fuel, but when distributed and sold for heating purposes has nearly the value of live steam taken direct from the boiler. There would be times of course when the demand for heating would be slight and when therefore it would be more economical to use a free exhaust, or, where there were several engines, to have only a portion of them deliver their exhaust into the street mains. The experiments of the New York Steam Co., previously cited, showed that the engines could easily be shifted from one exhaust pressure to the other without detriment to the light, and therefore be easily possible to secure at all times a maximum of economy which a combined system would permit.

So far as profits and dividends are concerned a very considerable saving would follow by the mere union of the two interests without even taking into account the value of the exhaust steam. Since, however, so much is dependent upon local conditions it is impossible to give figures which would apply to anything more than a hypothetical case. The amount of heat lost by radiation from the pipes of the New York Steam Co. showed the loss to be about 3 per cent. of the carrying capacity of the pipes. It may well be added here, as having a most important bearing on the profitableness of such an investment, some of the details of the cost of underground steam work. The sizes of pipe most common in practice are those having diameters of 4 in., 6 in., 8 in. and 10 inches, the carrying capacity of which with steam flowing with an initial head of 15 lbs. are respectively about 50 h. p., 150 h. p., 300 h. p. and 600 h. p. The cost of the underground construction, which includes valves and the special appliances, such as variators, service boxes, anchorages, insulation, etc., may be roughly estimated at $7.50 per foot for the 10 inch, $6.00 for the 8 inch, $4.50 for 6 inch and $3.50 for the 4 inch. In many instances where large buildings adjoin the lighting station, many of the appliances may be omitted and much of the expense spared which must usually be counted in the cost of long distance work.

The average price received for steam from the aggregate of consumers large and small is somewhat more than double the cost of producing the steam at the boiler house. This average price is one willingly paid by the consumer, owing to the saving in cost of labor and to the many conveniences, and advantages to be derived from having steam on tap like gas and water. Out of these gross earnings, which exceed 50 per cent. of the receipts, there must be subtracted the cost of maintaining the street system, leaving a balance applicable either for dividends, improvements or new constructions, or, as is often the case in new enterprises, this balance must be expended in reconstruction made necessary through defects arising from lack of experience at the start.

The entire annual gross receipts of a plant is, of course, limited by the carrying capacity of the pipes and may be estimated at about 40 per cent. of the cost of construction, and therefore net earnings of 25 per cent. will permit of 10 per cent. dividends. Since the cost of steam amounts to 50 per cent. of gross receipts, it is evident that if one-half of the steam sold for heating can be obtained from engine exhaust the saving effected in this way alone will amount to enough to pay a ten per cent. dividend.

In this paper I have attempted to show the complete, practical and commercial feasibility of combining a system of steam distribution from a central station with an electric light plant in a manner to utilize the exhaust.

I have given data that will assist in investigating the value of the plan in any locality where heating by steam could be introduced, but have purposely omitted to give any description or details of mechanical appliances and construction of underground steam work, as it seemed to me that the more important issue for discussion was the question: What has the distribution of steam from a central station to do with electric lighting?

ELECTRIC LIGHT AS APPLIED AND USED BY STEAM RAILROADS.[1]

BY W. H. MARKLAND.

AMONG the first to make use of the advantages afforded by electric lighting were the steam railroads, not as a means for lighting trains, but for lighting buildings, etc. In the year 1881 the Pennsylvania Railroad introduced its first electric lighting plant in a new shop in Altoona. That proved quite a success. It might also be mentioned that the same dynamo and lamps are in use today. In the year 1885 the Pennsylvania Railroad commenced lighting its depot shed in Altoona by arc light from its own dynamos, which proved a success as compared with the previous gas light, although it was crude to what the company now has.

The question then presented itself: Can freight yards be successfully lighted by electricity to reduce accidents, facilitate business and prevent breakage of cars and contents? The two latter items are quite a money consideration on any railroad. Some previous attempts had been made at lighting railroad yards by electricity, but without much success previous to the attempt in Altoona. I speak particularly of the Pennsylvania Railroad in Altoona, as I am very familiar with the lighting that has been done there, and also because what the Pennsylvania Railroad does is liable to be copied by other roads; and we sometimes get good ideas from other roads.

In Altoona, when drawing up the plan for lighting the yards, the question presented itself: How high and how near together shall the lights be placed? the problem of lighting the freight yard being more complicated than lighting a city; as in lighting a city lamps can generally be placed at street corners and quite low, the general public being not over-particular, so that under, or near the lamp, the light is quite brilliant, but in the space between lamps there is less brilliancy.

For lighting where engineers and trainmen have to work, it is not the brilliant light that is wanted, but the evenly distributed light. If a light be too brilliant, trainmen when near lamps will be partially blinded, as we might call it, for a short time; so in the event of their leaving a lighted space it would be difficult for them to distinguish objects or signals, and would lead to complaints.

In order to get an evenly distributed light, lamps at Altoona were placed on top of 65-foot poles, these being about eight feet in the ground, and set so as to illuminate switches and crossovers where the yards were narrow. Where yards were wide and long, lamps were placed about 600 feet apart, a row on one side of the yard and a row in a broad alley that was wisely left between tracks near the opposite side of the yard, the lights of the two rows being zig-zagged to prevent shadows and to better diffuse the light. This plan of lighting does not make a brilliant light at any point, it being possible, but difficult, to read fine print. A light more like moonlight was the result, and proved very good in practice. Even a clear globe was objectionable on account of the shadows of side arms. A lower-half ground globe was preferable, it having been proved by experience that it was better to lose a little light than to have shadows.

One noticeable result followed the introduction of this light. It enabled the car inspectors to examine cars much more thoroughly, and, as you all know, perfect car inspectors are very important. A decreased amount of pilferage also followed, as the watchmen were able to see persons at a great distance at night. The breakage of cars and their contents was but little, if any, greater at night than in day time. I cannot say how much money was saved by the introduction of the electric light from pilferage and breakage of cars and contents, yet I believe it was really more than the cost of maintaining the lights.

Undoubtedly the introduction of the electric light has prevented accidents to employés; of course I cannot say to what extent.

The electric lights are certainly a great help in shifting cars, as it enables the trainmen to see the tracks and position of switch points about as well at night as in the day time, on account of the light shining on the top of the rails, they being generally bright from passage over them, making a sort of reflector. Also in coupling and dropping cars it enables the brakeman to gauge the distance the cars are apart fully as well at night as in the day time, so cars can be coupled without any more jar or danger than by daylight. It also assists in dropping or switching cars very fast, as is often necessary during a time of increased traffic. It enables the switchmen in the towers to tell when a car is over a switch, so that they can quickly throw the switches with less danger of throwing the cars off the track or on the wrong track.

---

[1] Read before the National Electric Light Association, Providence, R. I.

A few words about the erection of arc lamps and poles for freight yards. Poles must be very well set in the ground, and guyed so as not to sway from heavy rolling stock passing, or from wind. The poles, being high, receive the full benefit of the wind. A good, true chestnut pole for lamps, if possible to obtain, answers very well. They will cost when shaved, stepped and erected with hood about $35. The price will be governed largely by the cost of timber. Short poles must also be well put up so that there may be no breaks.

Railroad people are very exacting; it does not do to have any stops or shut-downs. The lamps must be kept in good order. Maintaining arc lamps near railroads is quite different from maintaining lamps in most stores. If there is a poorly insulated part in the lamp, the soot will soon find a path for the current across the poor insulation, and out goes your lamp. Your cut-out contacts will corrode very fast. When it comes to your rods, expect to have a lot of dirty ones. In a railroad yard there are things to contend with not common with most lighting, and that is smoke and steam. I have seen poles covered from one end to other with a flim of soot from engines. This, in getting on the hanger boards is sure to make escapes unless the insulation be very good. The insulation should also be good to enable the inspector to work at a lamp in case of its failing to burn when the current is on.

Get a good reliable direct current double carbon arc lamp that is well insulated. A lamp that is heavy, bulky, or has liquids is not well adapted for the purpose, on account of the difficulty of carrying it up the pole. Do not rely on the hooks of lamps for connection between the lamp and the hanger board, or they will corrode and cause trouble. It is better to always put a piece of flexible wire from the hanger board to the lamp to carry the current. Always use a good insulated wire and good insulators when running up poles or side arms. It is better to splice on a piece of the very best insulated wire. Experience has proved that the wooden part of hanger boards is better for having some waterproof insulation between it and the side irons to prevent leaks.

I do not favor double-pole switches on hanger boards in freight yards, as they require extra contacts, the brass work of which soon corrodes so as not to make good connections, and leads to trouble.

The dynamo should be self-regulating and easily kept in order. As there may be 100 lamps, taking, say, two dynamos for all lighting at one point, it is better to put a little more money into dynamos than to pay high wages to the dynamo tender.

Keep as far away from telegraph and telephone lines as possible. If any damage is done to either of the above, the railroad generally gets the worst of the suit.

If you are going to hire the lights from a central station, see that they give you good work, and make a contract with a rebate and fine for the time lights are out.

If you once properly put electric lights in a freight yard, you will never get them out again; the trainmen will not stand it, as they would be in the dark in more senses than one, if the lights were taken away. But if the lights are not properly put in, say, on low poles, under 40 feet above ground, or not properly spaced, the chances are there will be complaints on account of too much light at some one point and too much darkness at some other point. Great care should be taken to place lamps so they will not interfere with signals. I have seen cases where electric lights were so placed that a signal could not be properly distinguished on account of the electric light shining on the lenses and blending the colors. A case like this can generally be avoided by placing some arrangement so that the electric light will not shine on the signal.

The electric light is rather a help to distinguish the position of the semaphore arm, although trainmen at night look for the color of the lens rather than the position of the arm.

The electric light is something of a help in distinguishing the switch signals, on account of the light shining on the lenses. These being low, the light will rarely show through them.

If it comes to a question of moving an electric light or a signal, you will find that the electric light will have to go every time, as railroads will not allow any interference with signals.

If you go too high, you will not get the full benefit of the light, as has been proved where the tower system of lighting is in use.

In laying out freight yards, a broad alley, say 12 feet between tracks, should be allowed for placing the lamp poles, where the yards are over 300 feet wide.

As to the other uses for electric lights for railroads, I do not know. I do not know that there is much out of the regular run. The light is used quite extensively for lighting depot sheds, where it is more economical than gas and decidedly better. This class of installation requires the very best of work and insulation, as the smoke and steam nuisance enters in here. Even though depot sheds are dry inside, porcelain knobs should not be used, glass with a double petticoat being the only kind now on the market that answers the requirements well, on account of the soot settling on the insulators.

It does not do to have a depot in darkness; for that reason a depot shed should be wired with two complete circuits, having every alternate lamp connected to one circuit and the remainder to the other. Then, in the event of a break in the wire, only one-half the lights are out.

Experience has proved that the arc light is much superior to the incandescent for depot shed lighting. With incandescent lights the necessary volume of light is costly to maintain, and also the globes of incandescent lamps soon become dirty from steam and smoke, which interferes with the light, or, if cleaned off, necessitates considerable labor.

For freight transfer stations the arc light is very satisfactory. It enables the men to quickly distinguish marks on merchandise and also enables the foremen to see what the men are doing, preventing loafing. One 2,000 nominal candle power arc lamp to about 1,500 square feet of floor space will generally light a transfer station where lamps can be zig-zagged. Where transfer stations are narrow, more light per square foot should be allowed. On a platform about 10 feet wide, as they generally are, one light every 60 feet gives good illumination.

I doubt if the arc light can compete with gas for this purpose as far as cost is concerned, taking transfer stations as they are, generally lighted by gas, and as they should be, lighted by arc lights. Yet I believe, taking the amount saved in labor and from pilferage, that the electric lights more than pay for themselves.

Another point comes in here. We all know that on a wet, dark day we do not feel inclined to work as we do on a bright, sunny day. The same is the case at night; if you give men good light it brightens their spirits up and they will work much more cheerfully; and getting men cheerful means more work done.

For offices and shops the electric light is used considerably, much the same as for other places of like nature.

I hear that an electric headlight has lately been brought out which, it is claimed, will illuminate a track for a mile or more. I am of the opinion that the light will not come into general use. In the first place, a light for this purpose should not be too strong, or it will blind an engineer coming in the opposite direction, this being a serious objection. Most of the roads east of the Ohio are not very straight, and the chances are that while on curves the neighboring cornfield will receive more light than the track ahead, as no one has invented a light that will show around the corner.

If any inventor wishes to get up an electric locomotive headlight, let him confine himself to one of low candle power—the present ones are about 20 c. p. I do not think one of over 100 c. p. will be in demand until railroads are illuminated from one end to the other by electric light, which will be the case in the future, and then the headlight will not be required.

These points are necessary for an electric headlight: First, and all important, reliability; second, simplicity. Economy you can leave out. If you can get 50 per cent. of what can be attained in a station, it will do. One thing must be borne in mind—engineers are not electricians. Thus a dynamo and lamp must be as simple as the air-brake, and no more liable to get out of order.

The experiment has been tried of lighting cars by electricity. While it has proved a success in some cases, as far as convenience is concerned, financially it has not proved a success. Electric lighting of trains is a luxury to-day, and will continue to be until some more economical plan is invented. The advance that is being made with the use of gas as an illuminant for cars is leaving electricity behind. From the best information I can get, it costs 50 cents per hour to light a car by electricity from storage batteries, against 5 cents per hour from carbureted air.

The electric light is used to some extent by different railroads for lighting wrecks or any construction work that requires night work. For this purpose the Pennsylvania railroad and the Cumberland Valley road have a car fitted up with boiler, dynamo, engine, water tanks and coal bunker, and all the tools necessary for a central station. With a car of this description, quick work in getting lamps in place is all important. In one case after the Johnstown flood, I, with the help of four men and the engineer, put up six arc lamps, put up the poles for the lamps, which were designed for the purpose and carried on the car, ran the wire, coupled up the lamps, and had the lamps going in 35 minutes from the time we, with the car, lamps, poles and wire, arrived on the ground. The lights were distributed some distance, one being about one-third of a mile away. I doubt if construction work was ever done quicker.

I will not go into a description of this car, as it was very ably explained by Mr. W. F. Taylor, of Altoona, at the convention of railroad telegraph superintendents at Niagara Falls, June 19, 1890.

To give an idea of what the Pennsylvania Railroad Company thinks of the electric light, I might say that its new Juniata shops at Altoona, having about 100,000 square feet of floor space, are lighted entirely by the electric light; there is not a pipe for illuminating gas in any of the buildings. All the traveling cranes are run by electricity.

The Pennsylvania Railroad Company believes that good electric work pays. I doubt if any station, central or isolated, has more reliable or better designed appliances, or more artistic work than can be found at the Juniata shops of that company.

ELECTRIC LIGHT WIRING INSTALLATIONS FROM A MECHANICAL STANDPOINT.[1]

BY AUGUSTUS NOLL.

THE question is frequently asked by architects and owners of buildings, "Can electric lights be installed with safety from fire, and will the installation give results that are satisfactory, and permanent?"

The improvements made recently, in materials and methods, admit of answering in the affirmative.

Nearly all the troubles in electric lighting plants have been caused by defective wiring, and on that part of the lighting system, more than on any other, depends the success of future service.

It may not be amiss to compare the early date of the art of electric light wiring with the present, and the probable future advancement in the methods of installation.

In the early days of electric lighting, a wire, covered with cotton, and saturated with paraffine, was used; this in a short time was replaced by a wire covered with cotton and white lead, known as "Underwriters' Wire;" the insulation was supposed to be fire-proof, and on that account, decreased the chances of fire; while the insulation was non-inflammable, it also readily absorbed moisture, which caused excessive leakage and some incipient fire; a few carefully conducted tests and experiments, proved that "protection against moisture was prevention of fire," and henceforth a moisture-proof wire was demanded, and the manufacturers in that line now offer us such high grade insulations as "Grimshaw White Core," "Okonite," and others.

Improvements in the method of installing the wires were also made; formerly buildings in the course of erection were equipped with the fire-proof insulated wire encased in wood mouldings, or inserted in zinc or lead tubes, but with the appearance of the moisture-proof insulated wire, the former insulation was discarded for the latter, and instead of inserting the wire in zinc and lead tubes, it was fastened directly to the side walls and ceilings, and covered by plaster. The cut-outs and switches are now mounted on porcelain and slate, instead of wood as formerly. More attention was given to the equalization of electrical pressure on conductors.

While these changes helped to improve the work, it was still a matter of chance that wires placed in a new building and imbedded in plaster gave satisfactory results; conditions that could not be controlled, increased the difficulties. A cut from the plasterer's trowel or a blow from a hammer on the insulation, destroyed its utility; and though the wires may be tested, the fault in some cases, would not appear till the building was completed, when, to remedy the defect, it was necessary to cut the plaster to obtain access to the wires, or discard the faulty circuits and rewire on the surface of the plaster, in either case disfiguring the walls and causing extreme annoyance; again, should changes be contemplated in the wiring, such as an increase of lights on different outlets, or a change to a lighting system where lamps of a lower voltage are used, we are once more confronted by work that is totally inaccessible, and to make the changes required, are forced to have recourse to the same expedients as stated before, and with the same results.

Although wiring installations gave better results than formerly, there was yet a large field for improvement; access to the conductors became absolutely necessary for controlling the system, making changes and rectifying defects which may occur after the work is finished and the building completed, and to do so without cutting or defacing the walls, or interfering with the other portion of the lighting system.

It is evident that as long as the conductors are inaccessible, just so long will the results be uncertain, and as it is our aim to eliminate the objectionable features and secure a wiring system that possesses accessibility and freedom from fire and leakage, the question is: "What is necessary?" To which I reply: A high grade moisture-proof insulated wire together with a system of "raceways" or conduits, and a complete line of "fishing" or junction boxes.

The conduits should be of ample size, with smooth inner surface, so that wires can be easily inserted or withdrawn; they should be constructed of materials that will not stain nor exude through plaster or paint, and should be non-combustible and moisture-proof; the action of lime or cement, or extreme variations of temperature, should have no effect.

The "fishing" or junction boxes should be equipped with shoulders or sockets for the entrance of the tubes, thereby making them a part of the conduit system, and preserving the continuity which is so essential in a system of this kind, and also enabling us to make the joints moisture-proof.

All cut-outs when single or in groups, should be located in the junction boxes.

The conduits should be installed in a workmanlike manner; they should not be run or looped from one outlet to another, but branches should lead to each outlet from the main conduit carrying the wire for that circuit, and at right angles with same; at the intersection of the branch and main conduits, a "fishing" box should be placed; the main conduits may be located in the cornice near the ceiling, or behind the base board at the floor with the cover of the junction box flush with the surface, thus keeping them out of sight and at the same time easy of access. The location of the conduits should be uniform on the different floors throughout the building.

An extra covering of metal should be placed on the conduits at the outlets, to keep them securely fastened to the wall, protect the ends, and take off the strain when inserting or withdrawing wires.

With a proper conduit and a complete system of junction boxes, it becomes unnecessary to insert a single wire (with the exception of the main feeders) until after the installation of conduits is complete, and the building finished; the insertion of strings or drawing lines is equally unnecessary, for, should the string or wire break near the middle of its length, that circuit would be as inaccessible as though it were imbedded directly in the plaster.

The main wires can be inserted in the conduits at the time of installing same, and placed in recesses in the walls, the cover of the recess to be detachable.

In hotels, apartment houses, office buildings, and other structures used for similar purposes, the largest part of the wires and conduits, together with the cut-outs and junction boxes, can be located in the halls, so that in case of alterations or additions being required, the occupants of the rooms will not be annoyed.

Considering the advantages a wiring system of this kind possesses over previous methods, a comparison in cost will be favorable to the conduit system.

The indefinite manner in which electric light wires are sometimes installed, has often placed the owner of a building, who contemplates changes, at the mercy of the company or contractors, under whose supervision the work was installed; they in turn delegate the foreman who had charge of the work in that particular building to attend to the changes required, and he usually tries to obtain the services of some of the wiremen who worked on the installation, because "they know where the wires lie."

It is apparent that the employment of a complete conduit system obviates these troubles, and also that instead of equipping a building with a wiring system suitable only for a special company's system of lighting, it can be fitted with conduits for electric lighting, regardless of system, and in fact, similar to piping the building for gas; and should a change in system be desired in the future where lamps of a lower voltage are used, the change can be made without cutting or defacing the walls, and at a nominal cost, whereas, should this change be required in a building where the wires are imbedded in plaster, it would practically necessitate the rewiring of the entire plant, and at a cost at least equal to that of the original work.

While a conduit of good insulation is necessary, it should not be regarded as extra insulation or protection, to an extent where the insulation directly on the wire is decreased, it should only be treated as a medium to accessibility.

"Prevention is better than cure," and for that reason only one wire should be placed in a conduit. Although the fusible metal cut-out will usually break the circuit in case of a "cross," still, it is safer to guard against any formation of this nature, by placing each wire in a separate tube, than to invite it by insufficiently insulated wire, or inserting wires of different polarity in the same tube.

Only the best is good enough, and will in the end be the cheapest for all branches of electric lighting.

The co-operation of architects is not only desirable, but necessary for the future advancement of electric light installation work, and to their credit be it said, that they are ever ready to extend their help; already have their suggestions been of value to us, and should the necessity of securing separate recesses be explained, they will, without doubt, make provision for the work similar to that made for gas, steam, and water pipes.

MUTUAL INSURANCE OF ACCOUNTS.[1]

BY FREDERIC A. C. PERRINE, D. SC.

THE recent financial crisis has been happily passed in a manner never before attempted or imagined in the history of business and banking. At any moment one of our sensation-loving newspapers, willing to handle fire, might have precipitated the whole country into financial ruin, by persistently teaching fear and liquidation, but, taking as they did, an optimistic view, they did not check the new force in banking, mutual support.

It may be objected to the use of the term new force, that "mutual support" is the very underlying principle of banking as it has always been practiced, but its application in approaching times of panic is almost new enough to be called a discovery. Mutual confidence in ordinary times is but the belief that any one, when individually called upon, can at any time meet his current obligations, but the principle applied by the bankers of Europe and by our New York clearing house, is essentially the belief in the solvency of the country, or the world as a whole. Two forces tended to bring about this happy result, one acting here and the other abroad.

---

[1] Prepared for the National Electric Light Association, Providence, R. I., Feb., 1891.

[1] Read before the National Electric Light Association, Providence, R. I.

In Europe the Barings were not the only bankers heavily involved in South American securities. They, indeed, were the heaviest holders of Argentines, and had taken the initiative in attempting to float them, but, failing in this, the load became too heavy for their individual shoulders, and their fellows were ready enough to give them aid which would also protect the smaller holders, in which number is included all except one or two of the great bankers.

Six months or more ago, the possibility of a crisis had been foreseen by our bankers, some of whom are intimately connected with South American affairs. By them it was known where lay the greatest financial dangers, and that these dangers concerned us only indirectly, through our speculative markets, rather than through the ordinary channels of business. When the crash came, and the worst was averted by the ready loan of gold abroad, our clearing house, feeling that a lack of confidence was the one dangerous element, ventured upon the experiment of the issue of a new form of currency, namely, the clearing house certificates.

Now that the air is clearing and we look about us, we find among the most sensitive lines of business the industry of electric lighting. Very few of the companies are thoroughly on their feet as regards ready cash, being but young, and spending their earnings in necessary extensions; almost none are individual concerns, the majority being stock companies, and, as a consequence, feeling immediately the the waves of the market. Many, noticeably the electric railroads, were in the midst of initiative constructions, and just about to float their bonds; but we can proudly say that nearly all were, and are, looked upon as successful business ventures, safe enough while confidence lasts.

These considerations have led to the thought that, without looking to outside bankers or business men, the electrical business should form an association of confidence, capable of rendering them independent of the market, if not even a stay to it, in future crises. It is thus that we see an association of confidence used by the bankers of the New York clearing house, and following immediately upon their action, the timely speech of Edward Atkinson before the Boot and Shoe Club of Boston, proposing its continuation as a general principle, and its extension to the needs of every day life, in a money issued by the clearing houses, based upon the stability of the business men of the country, and backed by a reserve in coin, only to be called upon in time of greatest need. In the course of his speech, to show how little the risk, he cites the fact that, in his extended experience of business, the losses through bad debts have not amounted to one-half of one per cent. of its value; this low average, I believe, has hitherto been much too high, applied to the electric light and railroad industries.

If, in view of these facts, the electrical companies would form a mutual association for the purpose of insuring their accounts, the effect would be that of increased capital in the business, relieving their creditors of much of their anxiety, and rendering stable the stock and bonds of the associated concerns. The risk of an account is not greater than that of anything else for which insurance is granted; a man's life, or loss by fire, for instance, while resembling rather the latter than the former. It is a calamity which no man expects, and one to be guarded against by the most strenuous means. The loss, stated above, of one-half of one per cent. as incident to general business, includes not only the losses due to bad management and dishonesty, but also the failures occasioned by these very times of weak faith, against which this plan is directed. These being eliminated, the business losses of an electrical company could be reduced to a minimum, and dividing these losses among the many, would make them a burden to none, while conferring upon all the benefit of a practically increased capital of a credit money.

In detail, the plan should be to form, among the electrical companies, a mutual assurance society, each company pledging individually its entire capital for the assurance of all accounts outstanding against any member, for which benefit a charge should be made covering expenses through administration or losses, proportionate to either the capital involved, or services rendered.

The assurance of the account could be effected in one of three methods, either of which would require elaboration and further study. First: the association might issue a series of promissory notes payable on demand, by means of which accounts could be settled, and which could be sold to various companies whose notes could be taken in exchange; this would involve a possibly expensive administration, and considerable ready capital, besides being probably liable to a tax imposed by the government on a circulating medium.

Secondly: the association might, without inquiry, insure all accounts, and be called upon only to adjust in case of failure. This would allow the greatest opportunity for dishonesty, and make it extremely difficult for the association to ascertain at any time its liabilities, except by a complicated system of bookkeeping involving the rigid inspection of the books of the insuring companies.

The third, which appeals to one as being the simplest plan, is that the association appear as an indorser on notes, or an insurer for accounts, when called upon to do so by any member, thus taking the position of a trust company. In the case of any one of the insured companies becoming involved, action should be taken by the association, depending upon the contingent circumstances; in the case of a temporary embarassment, the notes should be paid to the holders on maturity, and the company carried by the association till such a time as it could discharge its obligations. Were mismanagement apparent, the association should have the power to enforce a more economical or honest administration; or if, finally, the business were found to be necessarily unprofitable, the creditors should be paid in full and the company be closed out for the benefit of the association. No surrender of administration is contemplated here before such a time as the account could be shown to be in actual danger.

The insurance of an account may seem on first consideration to be rather a startling innovation in business methods, but I believe it to be based upon a firmer and more rational foundation than the insurance against loss either by fire or accident. Both of the latter are based upon a system of probabilities in which the insured expects his policy value to be greater than his premiums, and the success of the company proves it not to be true in the long run; the mutual insurance of an account, on the other hand, depends on the belief that all the accounts will be, in the main, stable, and that internal faith will induce a greater faith from the outside.

The objection that it is a scheme of the weak companies to be supported by the strong, and that they who would offer the greatest stability would not enter it, is answered in two ways: in the first place, as has already been said, the companies involved in the electrical businesses are in almost no cases individual concerns, and, as stock companies, are subject to extraordinary effects of bad and expensive management and fluctuations of the market; secondly, they are none of them so solid and stable as to be entirely removed from fear of depression, or need of funds for extension. Again, the very principle involved is that, as a whole, there are no weak companies in the business, if only times of depression be avoided.

To the objection that an unlimited liability company would be avoided by all, the same answers would be offered, with the addition of pointing to the Guarantee and Accident Lloyds, of New York, and Lloyds of England, as stable examples of the application of the principle to ordinary insurance.

The initial subscription of the small amount of a few thousand dollars by each insurer, would be the capital needed, its only use being to meet imperative accounts, while the administration would be of the simplest, requiring a minimum staff of efficient men whose services would be called upon to adjust irregularities and issue insurance.

This scheme is offered to the electrical fraternity, believing that by it the best interests of both the electric light and railway companies and the supply houses will be preserved, and that through it the electrical interests will not be a menace, but become a source of stability to the finances of the country.

REPORT OF COMMITTEE ON RELATIONS BETWEEN MANUFACTURING AND CENTRAL STATION COMPANIES.[1]

BY MARSDEN J. PERRY, CHAIRMAN.

THE functions of this Committee are almost defined by its title. The idea of, and the necessity for, this Committee, is to have a recognized counsel for mutual conference and conciliation in case either a Manufacturing or a Central Station Company should feel aggrieved by the business methods of those with whom they may have dealings, or be called upon to contend in business competition. In cases of this kind, the Committee can take no action unless requested so to do by one of the aggrieved parties. No such appeal has been made to the Committee.

This Committee is also intended to represent the general interests of Central Station Companies in case of unwarrantable competition in cutting prices for public lighting contracts, or to secure franchise rights in a town where a company is already in active operation and ready to perform all forms of service required, at reasonable rates. Your Committee is glad to state, that no case of this kind has been brought to its notice since the Twelfth Convention. It has, therefore, not been called upon to use the influence of the Association in that direction.

It is thought advisable to continue the Committee as one of the standing Committees of the Association. The time may come again, as it has certainly existed in the past, when it will be necessary for this Committee to exercise functions such as those indicated, or conduct negotiations of a different character under instructions from the Association.

---

[1] Presented at the National Electric Light Convention, Providence, R. I.

THE FERRANTI SYSTEM.[1]

BY CARYL D. HASKINS.

I keenly appreciate the compliment which your committee has paid me, in naming me to appear before you today to read a paper.

I fully realize that much is expected of me, and I believe I even more fully realize my inability to handle the subject with the completeness which I could wish.

My connection with Mr. Ferranti was not of long duration, and it is now some time since I severed my connection with him, so that my information, whilst pretty complete as far as it goes, is not as thoroughly up to date as it should be.

The Deptford station was far from finished when I left London, and 10,000 volts generated direct from the dynamo was still a matter for surmise and conjecture.

Under these circumstances the best thing I can do, I believe, will be to take up each feature of the system separately, and describe it to you in its various forms and applications as thoroughly as I can. Starting with this plan in view, I have arranged my paper under the following heads:

Methods of Distribution.
Ferranti Dynamos.
Ferranti Transformers, Fuses, etc.
The Ferranti Meter.

Starting then with Mr. Ferranti's methods of distribution, I will deal first with the old and somewhat famous Grosvenor Gallery station, from which current, at a pressure of 2,500 volts, was distributed throughout the most wealthy portion of London's West End, by means of overhead wires.

At the Grosvenor station there were two dynamos, each of 625 horse power nominal. These machines I will describe later on.

From these generators the circuit was carried to five double-pole, double-throw switches, each having a break of two feet and breaking both sides of the line at once.

Each of these switches represented a circuit, there being five circuits in all run from the Grosvenor station. It will readily be seen, therefore, that the switchboard of this station, which distributed light to no less than 35,000 lamps, was an exceedingly simple affair; yet, with their five switches, any desired combination of machines and circuits could be made.

It has quite frequently been stated, I believe, that these two machines at the Grosvenor were run in multiple. This is in no sense true, though, since the removal of these dynamos to Deptford station, they are to be connected in this manner, I understand.

From the five main switches the current was carried through Ferranti plug fuses of rather peculiar construction, having a break of two feet. These fuses I shall describe later. From the fuses the circuits were carried on ordinary wiring to an overhead distributing pole. From this centre the wires branched in five directions, being carried over the house-tops, and not through the streets as is our custom in America.

Stranded steel cables $\frac{7}{16}$ B. W. G. are stretched from pole to pole, and from these cables the mains are supported at frequent intervals by means of leather thongs or slings, thus saving undue chafing and straining of the conductors. This method of supporting the mains presents many marked advantages; the wear of insulation is reduced to a minimum, and the liability to a ground is very much diminished. The leather slings stand the wear and weather exceedingly well, and renewals are much less frequent than would be expected, especially if one take one's foot wear as a basis for calculation.

All streets are crossed at right angles, and no difficulty is experienced with the ubiquitous telephone man.

Contrary to the custom in this country, the primary wires are generally run into the house to be lighted, where they are connected to the transformer, a Ferranti fuse being placed in the circuit.

The secondary circuits are of 50 or 100 volts pressure, as may be required, and the house wiring is quite of the usual style, having a principal secondary fuse at the transformer, and a Ferranti recording meter in series with the lamps.

The Grosvenor Gallery, as a generating station, is now a thing of the past. It has been reconstructed, and is now one of the four transforming centres of the Deptford system, which draw their energy at the phenomenal pressure of 10,000 volts from the machines in the great station on the Thames.

This heavy pressure is reduced at these central points by means of large transformers, and is distributed over the London housetops at an E. M. F. of 2,500 volts in the manner I have already described, the only difference here being that these overhead mains are on a secondary instead of a primary circuit, and the house circuits become tertiary instead of secondary.

The portion of the Ferranti system of distribution which has given rise to the most interest, and which has been most talked of, is the present primary circuit, extending from Deptford to the four central distributing stations in London.

Many curious and wonderful letters regarding this have appeared in our journals at various times, and have given rise to much confusion and many wild conjectures, whilst the real facts of the matter are, I believe, but little understood.

The shape and principle of Mr. Ferranti's concentric main is familiar to all, but a few words descriptive of it may not be out of place here.

Over a copper tube, about 1½ inches in diameter, insulation is wound in the form of a stout manilla paper, thoroughly saturated with a special insulating compound. This insulation is wound on to a thickness of one-half inch by a machine specially designed for the purpose by Mr. Ferranti; over this insulation a second copper tube is placed, of the same sectional area as the inner one, and this is drawn down till tight.

The cable is made in lengths of 20 feet, and stands static tests of immense pressure. Special plug and expansion joints are provided for connecting the lengths, which are also thoroughly reliable.

The original intention was to lay these mains with the outer tube directly to earth throughout its entire length, thus rendering the system absolutely safe, since only one side of the circuit could be touched by the hand, and there would be no difference of potential between this and the ground.

Alternating circuits, and grounded telephone lines do not agree, however, and the law demanded that the Ferranti mains be laid duly insulated from earth; this is therefore done, but one terminal of the machine is still connected to ground, and comparative safety is the result, since it will readily be seen that to short circuit through the body, it would still be necessary to touch the inner tube of the conductor. This would necessitate cutting through the outer tube and insulation, which would mean a short circuit from tube to tube, through the cutting instrument, a dead short-circuit on the machine, certainly, but perfectly safe for the meddler.

At the collector boxes of the machines an accident is impossible, since the collectors are enclosed within an iron box, the lid of which is magnetically locked by the exciting current—nor can the machine generate when the box is open, since the exciting circuit is not complete till the box is closed.

Unfortunately time was an object in the starting of the Deptford station, and much contract-made cable was laid; the greater part of this was the lead-covered cable so frequently mentioned; this was not of the concentric pattern, but an ordinary stranded cable—I understand that it was guaranteed to stand considerably above 10,000 volts, but after being laid it was found not to stand 10,000 at all, and to give but poor satisfaction even at 5,000.

This unfortunate trouble has given rise to much talk, and has been scarcely well understood by the general public.

Several other kinds of cable were tried, but gave equally unsatisfactory results, and all mains have, doubtless, by this time been replaced by the Ferranti concentric cable, which stands the pressure perfectly, and gives most satisfactory results.

Of the various expedients to which Mr. Ferranti had recourse during this trouble with the cables, I am not prepared to speak, first, because I am not fully informed regarding them, and secondly, because they form no portion of the Ferranti system of distribution. They were simply makeshifts, necessitated by an unfortunate happening, and by lack of time, and they have probably given rise to more discussion, both in and out of the papers, than has the system itself.

I will now pass on to a description of some typical Ferranti dynamos. First among these, a few words are due to the original form of Ferranti alternator, which, while it is no longer manufactured, still, without doubt, was a machine of marked efficiency and great originality.

The characteristics of this earliest dynamo are, I think, about as follows. The figures are not based upon my personal experience, for the machine was out of date long before my time, but upon various fragmentary notes from my pocketbook, and a generous quotation from Thompson's "Dynamo Electric Machinery."

As in the Siemens machine of similar type, the fields formed, as they do now, "two upright circular crowns of electro-magnets with opposing poles." There were 16 magnets on each side; 32 in all.

The peculiarity of the machine lay in the armature, which consisted of a series of zigzag loops, eight in number, wound or folded one layer upon another, and separated by alternate ribbons of strip insulation of similar width. The winding was in three multiple circuits, each strip making 10 turns around the zigzag coil 30 layers of winding in all.

Each of these three coils is connected at one end with a solid star-shaped brass boss, which, bolted together from either side through the loops of the zigzag coil, form a solid centre for the disc armature, and at the same time connect directly with one of the collector rings; the three coils all again uniting in an inner star-shaped piece of brass, which in its turn communicate with the second collector.

This disc armature was 30 inches in diameter and one-half-inch thick. Its extreme thinness permitted the magnet poles to be brought very close together, enough space only being allowed to insure safe clearance. The natural result of this was a very efficient field.

---

[1] Read before the National Electric Light Association, Providence.

The dynamo was calculated for a speed of 1,400 revolutions per minute, and maintained a pressure of 100 volts. The armature weighed less than 100 pounds, and the entire machine rather less than 1½ tons.

Most of these old machines are still in use, principally upon British war ships, and are doing good service.

An excellent type of all the more modern Ferranti machines is the 150 horse-power dynamo, which has been manufactured in considerable numbers, and is the alternator generally in use in most of the smaller stations using the Ferranti system.

In this machine the number of parts has been reduced to a minimum, and the efficiency is very high; it will fully illuminate 8,000 ten candle-power lamps, requiring an average energy of over 35 watts each.

The fields are arranged as in the old machines, and have 20 magnets on each side. The distance between the opposing faces of the fields is rather less than three-quarters of an inch, and within this narrow space the coils of the armature rotate at a speed of 400 revolutions per minute. The armature being four feet in diameter, this makes a peripheral speed of 4,800 feet per minute. The diameter of the armature shaft is 4½ inches, which at first sight seems rather large, since there is no great weight to carry, but the size is needed, since the armature is overhung.

This armature is without iron, and consists of a central boss of gun-metal, into which are fixed 10 carrying-arms of brass. These are insulated from, and held into, the core by a special mixture of sulphur, which is poured in in a liquid state and sets harder than metal itself.

This sulphur insulator is one of Ferranti's specialties and prides, and much of the success of his machine is, I believe, due to it. I never, during my stay with him, met with a ground on an armature shaft.

Each of the ten carrying-arms which I have just mentioned, holds two coils or bobbins of copper tape, tightly wound by machinery on a centre made up of alternate strips of asbestos and brass. Terminating at one extremity is a gun-metal butt-piece, the entire coil being fastened to the carrying-arm by a single bolt passing through this butt-piece, and drawing the bobbin into place.

The winding of the bobbins themselves is of alternate layers of corrugated copper and fibre ribbon, the object of the corrugation being to prevent lateral slipping—a very necessary precaution.

The thickness of the bobbins, which form the only portion of the armature projecting between the fields, is one-half inch, which leaves a margin of less than one-eighth inch clearance on each side.

The coils are connected in two parallel circuits, which are conducted away through the carrying-arms and the rods within the central boss itself, to the collector rings, where the current is taken off by Ferranti collectors—two half circular pieces of metal like the two halves of a severed ring, which almost surround the collector rings, and are held together by bronze springs, making an extremely good and constant contact, and not running at all hot.

The machine can be very quickly repaired; the two fields are divided at the centre, and slide back very readily, right and left, on extension bases, by the the aid of a simple levering device. The armature is then exposed, hanging in its usual position, and it is but the work of a moment to take out and replace a burnt coil with a new one.

A few details regarding the two 625 horse-power machines formerly used at the Grosvenor station, and now being installed with changed winding, to take the light day load at Deptford, may be of interest here, before I pass on to a description of the giant machines of the Deptford station. These two dynamos are in construction almost exactly like the 150 horse-power type which I have already described. The machines were originally designed to give current for 10,000 ten candle-power lamps each, but have frequently carried as high as 19,000 lamps without apparent effort. The weight of these dynamos is 35 tons. The height from floor is 9 feet 6 inches; the floor space required, 9 feet by 11 feet; armature diameter, 8 feet 6 inches; potential maintained, 2,500 volts; speed, 280 revolutions per minute.

There are 40 coils, or bobbins, in the armature, and 40 field magnets on each side; 80 in all. The pulley is grooved for rope driving, Mr. Ferranti being fully convinced that this is infinitely better than the best belting.

It has probably been already remarked that I have made mention of no regulating device for the dynamos. Mr. Ferranti makes no provision for automatic governing, nor is it needed. It must be remembered that there is absolutely no iron in the armature, and that the machine is, therefore, self-regulating to a very large degree.

There is no compounding of the field, the field circuit being entirely simple and separate. At the Grosvenor, the exciters used were Siemens machines, giving 108 amperes at 100 volts. At Deptford, Kapp machines coupled direct to Allen engines are used. These Kapp machines have rheostats in their field circuits, not for use in regulation, but in starting up and in case of emergency. It will be noticed that the two machines I have just described have not armatures arranged with the zigzag winding, adopted in the original Farranti machine. This zigzag winding was abandoned for several reasons. It was impracticable for large armatures and a winding made up of separate bobbins, or coils, which could readily be removed and replaced, was found to be exceedingly desirable. To meet these requirements, therefore, the method of winding was changed to an arrangement similar to what is generally spoken of in text-books as the "Siemens alternating armature."

It now remains to me, before passing on to the less important apparatus of the Ferranti system, to give a brief description of the two sizes of dynamo which are installed, and being installed at the Deptford station.

So much has been said and written about these during the past year or more, that I almost hesitate to mention them at all, so sure do I feel that almost every one here is familiar with their general character and dimensions.

The Deptford machines will be of two sizes, the portion of the station to be put into immediate use, calling for three dynamos, two of 1,500 horse-power each, and one of no less than 10,000. Of these the two first are now installed and running, whilst the 10,000 horse-power machine is still in course of construction, it being far too enormous a piece of machinery to admit of hurrying.

Each of the 1,500 horse-power machines is driven by means of 40 five inch ropes from a compound vertical condensing engine of marine type, having a grooved drum or driving pulley 24 inches in diameter.

The carrying-arms of the armature, which support the winding, are fixed directly into one end of what may be called at once the pulley and the armature boss, by means of sulphur insulation. Into these carrying arms are fixed the 48 bobbins which constitute the winding. The total diameter of the armature is 12 feet 6 inches. The fields are arranged as in the smaller machines and have 48 magnets on each side, 96 in all. The copper strip composing the winding of the armature is three-quarters of an inch in width, and 1½ millimetres in thickness.

There is only one inch of space between the opposite magnet poles, and within this the armature rotates, having one-half inch clearance on each side.

Small fan-shaped ears are cast onto the carrying-arms of these, and the other machines which I have described, which, when the machines are in motion, force a constant current of air between the armature and the field, keeping up a very perfect ventilation, and removing any dust which might accumulate upon the face of the magnets. This dust, if allowed to remain, would be apt to cause a short circuit from winding to magnets, as one pole of the machines is to ground; as an additional precaution against this the faces of the magnets are covered with a thin layer of vulcanite.

The frame divides as in the smaller machines, and slides back on extension bases to afford access to the armature, a special engine being provided to do all this work.

Of the 10,000 horse-power dynamo, I can say but little; it will differ from the others only so far as its enormous size renders necessary. The armature will be no less than 40 feet in diameter, and will rotate at a speed of 60 revolutions per minute. It will be coupled direct to two compound vertical condensing engines, each of 5,000 horse-power, one on each side of the armature.

The shaft is the largest forging ever turned out of the celebrated Clyde workshops, and one of the largest ever made in the world. It is no less than 36 inches in diameter, 28 inches in the bearings. I really do not dare state its weight. There will be 132 bobbins in the armature, and 132 magnets on each side. The enormous size of this machine is quite beyond the comprehension of one who has not seen its parts.

The station instruments which are used in connection with the Ferranti dynamo, are the Sir Wm. Thomson gravity direct-reading ammeter, and the Sir Wm. Thomson statical voltmeter.

I will now pass on to a brief description of the Ferranti transformer, meter, etc. I am aware that I have been able to give but the merest outline of Ferranti's dynamo construction; the subject is far too intricate and wide a one to be treated at all in detail within the limits of a short paper.

Before describing the Ferranti transformer, I should say a few words about the Ferranti fuse. Its position seems naturally to be between dynamo and transformer. This is an exceedingly simple device of porcelain, having a long break. It consists of two removable plugs, to which are fastened a number of thin strands of fuse wire, according to the current to be carried. These wires pass through a narrow crevice or slot in the earthenware, from plug to plug, the crevice being broken at short intervals by cup-shaped hollows, this construction preventing arcing. The fuse has a convenient earthenware cover, can be placed anywhere, and has always proved entirely trustworthy.

The Ferranti transformer is seemingly as little known as the dynamo in this country. It is a very simple affair, of decidedly high efficiency, consisting of a number of bundles of very thin soft hoop iron, spaced apart with wedges clamped tightly together and wound at their central portion with insulation. Each strip of iron is insulated from its neighbor for half its length on each side by paper pasted on. This, when the irons are turned back, as I shall presently describe, leaves a strip of paper between each layer of iron, but does not prevent a perfect magnetic circuit.

On these bundles of irons, at the portion wrapped with insulation, is wound the secondary, which is in its turn wrapped with insulation; on to all this the primary is slipped, in the shape of a number of coils, wound elsewhere on former blocks. These coils are slipped on, one by one, and separated from one another by washers of shellaced cardboard.

The projecting irons are then turned back over the coils from each end, lapping each other, first one way, then the other, like shuffled cards, and the last two are fastened off by a simple double "L" or tinsman's joint. Half of each bundle is turned back in each direction, up and down, forming complete magnetic circuits in two directions.

The transformer is extremely convenient in case of repairs, when the irons are readily straightened out and burnt primary coils replaced.

It seems, however, to have several marked defects, the flat side of the lamination is presented to the penetration of the lines of force, which, according to Kennedy, is incorrect construction, and the transformer is inclined for this reason, both to heat rather badly, and to hum, the latter trouble being partly due doubtless to the fact that the iron cannot be held so firmly in this style of converter as in the more common type, where the iron forms a solid block.

The transformer is incased within a cast-iron shell, from which it is insulated, and into which the primary and secondary terminals are fixed by means of the Ferranti sulphur insulation.

These converters are made in five sizes: 25, 50, 100, 150 and 200 lighters. The large transformers for reducing the 10,000 volts of the primary to the 2,500 volts of the street circuits, are of the same construction as these I have just described, the insulation being, of course, increased to bear the enormous pressure.

This is not the original transformer used by Ferranti; that was of the Gramme ring type, and rather more efficient than the present one, I believe, but scarcely practical from a mechanical standpoint.

There now remains to describe only the Ferranti meter, a most ingenious recording instrument largely used in connection with Mr. Ferranti's London circuits. This meter consists of a coil, of a few turns, in series with the lamps, which passes around a core of soft iron, and terminates in a composition metal ring, which is split to prevent Foucault currents, and is bolted on to a soft iron base, being, however, insulated from it. Thus it will be seen that the ring, the base, and the soft core around which the coil passes (the lower portion of which is burnt or cast into the ring also), form, respectively, sides, bottom and top of a hollow and tight trough; the iron is continued from above the coil, by means of a horseshoe shaped laminated piece of iron which passes down outside of the coil and makes contact with the base; thus we have a magnetic pole at the top and bottom of the trough.

This trough is filled with mercury, making contact with three-fourths of the inner circumference of the ring, and the centre of the base. The current entering the coil, passes around it to the ring, and from the ring through the mercury to the base on which is the other terminal.

Under the combined influence of the magnetic field and the current passing through the mercury from centre to periphery, and *vice versa*, the quicksilver is caused to rotate.

A shaft passes from a jewel in the base, through a small hole in the iron core to a train of wheels at the top; on this shaft is an aluminum fan suspended in the bath; this is all balanced so nicely that it actually floats in mercury.

Now, since the resistance to rotation due to friction is approximately proportional to the square of the speed, and the turning moment is proportional to the square of the current, the number of revolutions performed in a given time is a measure of the current which has passed through the meter during that period.

Owing, however, to the rule of friction not following this law absolutely, and owing to the additional and irregular friction of the gear, a sensible error is introduced. This difficulty is overcome by placing a shunt coil of high resistance around the series coil, which secures an excess of electro-magnetic action, when the friction is greatest in proportion to the torque, thus assisting the low loads.

The meter is very accurate, and has a quite wide range, 1 to 50 amperes being the capacity of the 100 volt instruments; it is equally serviceable on direct or alternating circuits of any frequency.

This meter, while undoubtedly accurate, has many very apparent weak points, however; the mercury volatilizes quite rapidly, especially when the instrument becomes warm; the meters must always be kept upright or their contents will spill, and they cannot be carried from place to place without being emptied and refilled, which, as the quantity of quicksilver varies, is apt to introduce errors. In view of these troubles Mr. Ferranti is now also manufacturing and using a number of meters of small capacity, similar in principle to the well-known Shallenberger instrument, which are sufficiently accurate for general use; these are manufactured under the English patents of Mr. Wright, one of Mr. Ferranti's staff.

REPORT OF THE NATIONAL COMMITTEE ON LEGISLATION. SECTION FOR THE DISTRICT OF COLUMBIA.[1]

BY GEORGE C. MAYNARD.

It has been my special duty to look after Senate Bill No. 4,329, introduced by Senator Hale on the 15th of August, 1890, and referred to the Committee on Census.

A copy of memorials adopted at the Twelfth Convention, was mailed to all members of the Association and to Boards of Trade and Commercial bodies, from the office of the Secretary, in New York. In addition to these, 500 copies were mailed from Washington to various other persons and corporations.

Resolutions strongly urging the passage of the bill, adopted by the following-named organizations, have been presented to the Senate and referred to the Census Committee:

National Board of Trade and Transportation, New York City. Indianapolis Board of Trade, Indianapolis, Ind. Master Builders Exchange, Philadelphia, Pa. Chamber of Commerce, New Haven, Conn. Merchants Exchange, St. Louis, Mo. Retail Grocers Association, Lincoln, Neb. Commercial Club, Kansas City, Mo. Association of Edison Illuminating Companies. Norwich Board of Trade, Omaha, Neb. Wilkes Barre Board of Trade, Wilkes Barre, Pa.

In response to the memorials sent from Washington, I received from a considerable number of prominent companies and individuals replies that special personal appeals had been made to Senators and Representatives, asking their support of the bill. Accompanying these replies were copies of letters from many Senators promising their cordial support of the measure whenever it should come up.

These communications were from:

The Standard Underground Cable Co., Pittsburg, Pa., The Utica Electric Light Co., Utica, N. Y., Citizens Illuminating Co., Brooklyn, N. Y., Wheeling Electrical Co., Wheeling, W. Va., The Simplex Electrical Co., Boston, Mass., J. J. Burleigh, Camden, N. J., Wm. B. Wilson, Philadelphia, Pa., F. B. Knight, Austin, Tex., Geo. N. Stone, Cincinnati, O., M. B. Leonard, Richmond, Va., H. B. Chamberlin, Denver, Col., Geo. M. Dugan, Jackson, Tenn., Noah H. Cheever, Ann Arbor, Mich.

In addition to this work which is of record, a great deal has been done by members of the Association and others, by private letters to, or personal interviews with, Senators or Representatives.

So far as learned, not a single Congressman has made any objections to it, and nothing but the extraordinary pressure of important business has prevented its passage. It may reasonably be expected that the bill will pass at this or the next Congress.

REPORT OF THE COMMITTEE ON UNDERGROUND CONDUITS AND CONDUCTORS.[2]

BY C. H. WILMERDING, CHAIRMAN.

The committee on underground conductors begs to submit the following report for the last half year. The change which was made recently in the chairmanship of this committee, delayed to a great extent, our active work on its part. The further delay in getting our printed matter, which it was intended to send to all companies operating underground conductors, has left us without any information on the subject in hand. It was proposed to follow out the lines indicated in the report of the committee at the twelfth convention. Only one company has reported, viz: The Chicago Arc-Light and Power Co., which reports as follows:—

Miles of duct occupied by high tension underground conductors	$28\frac{1}{2}$
Miles of lead-covered cable in ducts	29
Miles of cable in iron pipes or bracketed under sidewalks for distribution	72
Total number of miles of underground high tension cable	151
Total number of cases of trouble on underground cable 1890	31
Divided as follows:—	
Result of mechanical injury	18
Result of defective joints	4
Result of defective insulation	2
Other burn-outs, cause not accurately determined	7

During the year 1890, $33\frac{5}{10}$ miles of underground conductors were laid by this company, and during that period there was one case of trouble on this $33\frac{5}{10}$ miles, the trouble being in a defective joint. They further report that their rebates during the year for defective service amounted to one-third of one per cent. of the gross earnings; and they estimate that possibly one-third of these rebates are attributable to circuit trouble; the balance to defective lamps, dynamo and engine trouble and miscellaneous causes.

---

[1] Read before the National Electric Light Association, Providence, R. I.

[2] Presented at the National Electric Light Convention, Feb. 17, 1891.

The longest underground circuit is 7½ miles from pole to pole, and carries an electromotive force of 2,500 volts. They add that blizzards have not in any way affected their service.

The committee in offering this report, realizes that the information is of a very meagre character, but is of the opinion that if similar reports, or still fuller reports, should be had from all companies operating underground conductors, very interesting and instructive data could be laid before the Convention; and they request that when questions are published and sent to various companies, they will receive attention, and that the information required will be given fully and cheerfully by all those whom the circulars may reach.

THE ORGANIZATION OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.[1]

BY CHAS. W. PRICE.

A FEW hours ago I was informed that owing to the absence of Mr. Worthington, I would be expected to respond to this theme—"The Organization of the National Electric Light Association." Providence with an electric light convention let loose upon it, is not the best place in the world to collect your thoughts. This, you must accept as my apology for the hurried and brief remarks I shall make, and that they are brief, no doubt, you will be thankful.

Fortunately for me, though perhaps not for the Association, I was present at the birth of the National Electric Light Association, an organization which through many changes of everything else has never changed its name, and is still known by the title given it in Chicago six years ago. I think every line of the first Constitution and By-Laws has been changed with this exception, for when other portions of the programme failed, a report from the Committee on Amendments would be depended on, and such Committee was appointed as regularly as the Association assembled in convention. These amendments were not always improvements. Having had an humble part in the construction of the first Constitution, you will understand of course I can speak from an unprejudiced standpoint.

The first convention was composed of many of the pioneers in electrical work, energetic and progressive men. Next to those engaged in electric lighting, gentlemen representing the carbon industry were the most numerous—not even excepting at that time the newspaper men—and our friends who dealt in general electrical supplies lent friendly and able aid at all times No one seemed to fully understand why the meeting had been called, one delegate stating at the first session that he came because his parent campany advised him not to.

The first meeting of the National Electric Light Association was held in the parlors of the Grand Pacific Hotel, Chicago, at 11 o'clock, a. m., February 25, 1885, six years ago. Mr. William A. Hovey, at that time one of the editors of *The Electrical Review* of New York, called the meeting to order, and stated that the call had been issued by his journal on the request of a large number engaged in the business of supplying electric light.

George S. Bowen, Esq., then with the Van Depoele Electric Company, of Chicago, was elected temporary chairman, and Mr. Henry Dwight Stanley, then, and now, and probably forever, representing the Bridgeport Brass Co., was elected temporary secretary. Mr. Bowen on taking the chair spoke briefly of the bright future he thought was in store for the electric light, remarked that the science was "still in its infancy," and expressed a confidence that valuable results would grow out of the Convention. You all agree, undoubtedly, with Mr. Bowen's predictions.

A Committee on Credentials and Permanent Organizations was appointed, consisting of the following named gentlemen: Charles A. Brown, of Chicago; C. J. Richards, Racine, Wis.; George Herbert Wadsworth, of Cleveland (since deceased); Frank Ridlon, of Boston, and S. Baldwin, of Baltimore. A Committee on Programme and Progress of Business (please note the title) consisting of about one-third of the delegates to the Convention was appointed and then we adjourned for lunch.

On re-convening, Mayor Carter Harrison, of Chicago, welcomed the visitors. Speaking from memory, I remember that he said that "Electricity was the most subtle of fluids, that it was the most powerful, the greatest agency handled by man. It was," he said, "the breath of Deity. It could rend the giant oak, melt the granite of ages, yet in the incandescent light it was as soft as down on a woman's cheek." Then we all stood up and cheered Carter Harrison.

Prof. Elisha Gray also spoke a few words of welcome, and gave electricity the credit of being the greatest wonder of the century, and varied the "infancy" remark by predicting that we were only on the threshold of its wonders. Then all applauded Prof. Gray, and everybody present felt proud of his calling.

The Committee on Permanent Organization, which had been penned up in a room, and compelled to go hungry until the report was made, then filed into the room. The peaceful look on their countenances gave no indication of the strife and controversy that had occurred in that committee room, where they had been in attendance on the birth of this Association. The Committee was fortunately a comprehensive one, and from a host of candidates made admirable selections, as follows, and the report was unanimously adopted by the Convention: President, J. F. Morrison, Baltimore; vice-presidents, H. M. Cleveland, of Hartford, Conn., J. H. Yarbrough, Nashville, Tenn., E. R. Weeks, Kansas City, Mo.; secretary and treasurer, William A. Hovey of New York; executive committee, George S. Bowen, of Chicago, William Hochhausen, of New York, Gilbert Donaldson, of St. Paul, Frank Ridlon, of Boston, John R. Fletcher, Akron, Ohio, and Geo. O'Connor, of New Orleans. Mr. Morrison thanked the Convention for the honor, and in a brief address, opened the Convention for the business that had brought many of the members hundreds of miles.

The committe on digest of papers and programme of business reported the following order of proceedings and topics for discussion, which I think will not be uninteresting to give in full here: 1. Incandescent light, particularly in regard to length of circuit upon which they can be run with profit. (You will see even at that time, these scientists and engineers were not working solely for their health.) 2. Locating and avoiding crosses with telephone wires. 3. Power and its conversion into light. 4. Electric light globes and shades. 5. The best modes of connecting dynamos with power. 6. Electric lighting by water power. 7. Rates and rebates on electric lights by the year. 8. The use of electricity as applied to motors. 9. When an electric light system requires No. 6 conductor, is it desirable to use Nos. 6 and 4 in the same line? 10. Will armatures become affected by frost when exposed in transportation? 11. Special insulation or guards to insulation of lines at dangerous points and places. 12. Street lighting—the best manner and modes of accomplishment, embracing the location of lights and running of circuits. 13. Experience and results in the use of underground conductors. 14. *Resolved*, That the firemen should receive more pay than the engineer. 15. Help generally. 16. Experience of electric light companies in the use of copper coated and uncoated carbons.

In the light of the present, the discussion which followed would prove very interesting, and in some instances laughable. But the Convention report which was published, gives you all this and I need not make lengthy mention here.

I remember that the Convention was astonished by the figures given by Mr. George Fletcher, of Dixon, Ill., of the cost to him per light. Some one asked him how much he paid his engineer. Who was his engineer? "The good lord is my engineer" said Mr. Fletcher. This he explained by stating that he employed water-power, by means of which a turbine water wheel ran a saw-mill and other mills, and incidentally his electric light plant. Mr. Van Depoele stated that electricity could be used for transmitting power. No one will dispute that fact to-day, or that Mr. Van Depoele was one of the first to prove it.

Proposition No. 9, relating to the use of the No. 6 and 4 wire in the same line, was decided in the affirmative. Whether frost could damage armatures in transportation was answered in the negative by Mr. VanDepoele.

The principal sections of the Constitution and By-Laws as adopted were as follows:—

ARTICLE II.—The members of this Association shall be companies, firms or individuals operating electric light plants or manufacturing electric lighting apparatus.

ARTICLE III.—Companies, individuals or firms engaged in the manufacture of machinery or apparatus connected with electric lighting may be admitted to associate membership by a vote of the Executive Committee. Such associate members shall pay the same dues as members, shall be entitled to seats at all meetings, but shall have no vote, shall be ineligible to office, and shall be entitled to the floor only at the request of the Executive Committee or presiding officer.

This Convention adjourned after a two day's session, and its subsequent history you are all well acquainted with.

In conclusion, it is scarcely necessary for me to speak of the great usefulness and wide influence of this Association.

Starting with a membership of less than fifty, it now has, I believe, several hundred, and it has been the means of promoting a fraternal feeling thoughout the entire electrical industry, of at once bringing to the front the most meritorious work of the alert inventors, and to an extent not easily calculable, made every electric light man acquainted with the most successful and modern manner of conducting his business. Neither can it be said to have fulfilled its mission. There is much, and still greater work to do as this great science continues to expand. No organization, and I speak advisably, has done as much to promote the best interests of the whole field of this industry as your Association.

That the good work begun in doubt and with many misgivings in the city of Chicago six years ago, may continue to still greater usefulness and honor, is the sincere wish of your present speaker.

---

[1] A paper read before the National Electric Light Association, Providence, R. I.

ON THE DISTRIBUTION AND CARE OF ALTERNATING CURRENTS.[1]

BY T. CARPENTER SMITH.

I FEEL some reluctance to treating of this subject at all, because I have already spoken upon it at two or three conventions; but it has been brought to my notice that while a good deal of it is an old story to some of us, there are new stations starting up every day, and it is to those people that I address myself more particularly. I want to keep them from falling into the same holes that we fell into, and I do not think there is anything that has hurt the business more than the failures in it; I do not mean the practical or the working failures, but the commercial failures. The men who put their money into these original plans, without any knowledge, and who did it on the faith of their engineers, and who found that they did not get a sufficient return from it, are not only loath to spend any more money themselves, but they exercise a very bad effect on others when we try to influence new capital.

I will begin by stating that there are a great many points covered in the care of the alternating currents as used for electric lighting that apply with equal force to all others at present in use for commercial purposes. It is always the unexpected that happens, and no doubt many points arise in practice which are never known outside of the station in which they occur, being treated as matters of course. If, therefore, I seem to omit any point which should be covered, it must be remembered that it is my intention as much as possible to avoid recapitulation in such cases, but only describe some peculiarities of alternating current distribution which render certain precautions especially necessary and valuable.

To more easily arrive at these, it will be well, however, to briefly state the different forms of electrical currents now in commercial use and what we may call the governing characteristic of each. I leave out those which come first in the history of the question; namely, telegraph, telephone, district call and fire alarm current. They are only worthy of note for their generally poor installation, the telephone lines especially being a perpetual nuisance to all of the others. This arises chiefly from their being of such light gauges of wire that they will not stand any exceptional strain, such as is placed upon them by sleet storms or heavy gales, while the effect of rust and deterioration from atmospheric causes rapidly reduces them to the point beyond which they will not carry their own weight. I need not say that the moment they fall upon any electric light or power wires they become a menace, not only to the company operating the wires on which they fall, but themselves become dangerous to passers by in the streets who have not yet learned that any dangling wire is worthy of avoidance.

Perhaps the strongest reason why these wires are present in such overwhelming numbers in most cities is the fact that their value as "scrap" material will not pay the cost of taking them down. In other words a short sighted policy decides that it is cheaper to leave them up, and they are abandoned until they either fall down or are taken down by some other company which has reason to fear them.

The first that we consider of the currents now in general use from central stations are the "Arc Lighting Circuits." To take the most powerful current generally operated on this system we may place it at about 10 amperes, and from 2,500 to 3,000 volts on a single wire. In this current we have, as a rule, the governing characteristic of a very high tension, but with small volume; and it may be well to note the particular form of danger to which it gives rise. Its high tension makes it dangerous both as to life and fire, from its liability to leap through the insulation, and, when the current has once been started, to form a long arc. On the other hand, the danger is limited by the fact that the volume of current is small, and that the short circuiting of the line by any other conductor tends, as a rule, to simply cut the lights out, rather than to cause any great danger at the point where this happens, while nearly all the machinery of this type in general use automatically reduces the energy supplied at once.

The chief points to be guarded in these currents are therefore practically covered by the general precautions of good insulation and protection against leakage by moisture reaching the wires, while the danger to life is very largely eliminated by the usual practice of placing all lamps and appliances well out of reach of the public, and confining their care entirely to employees who are presumably skilled, and who will therefore handle the matter intelligently.

In the second great division of electrical currents which we consider, the "low tension direct current" system, the ruling feature is the large quantity. We may say that this current is practically not dangerous to life, but very dangerous as regards fire if not properly installed and protected. It is, however, a simple matter to properly protect these wires, and the low tension not putting any great strain on insulation, we may discuss it as fully covered by the ordinary rule of the fire insurance underwriters, who, in this respect, owing to the nature of the business, have even more interest in the saving of property from fire than the central station itself. The great danger, however, lies in the fact that the volume of current is so great that any short circuit on the main lines develops an enormous amount of energy at the point of accident, sufficient—on the authority of Mr. Edison himself—to reduce the pavement to a molten mass for many feet. The general public, almost necessarily, have considerable care and control of the distributive appliances and in their ignorance will often put grounds on the wires, or replace fusible plugs by copper wires; and this all has to be watched for.

And that is a danger that I think central stations ought to interest themselves more in. In Philadelphia we have got to a very good point with the fire underwriters, and they keep inspectors constantly at work; they do not merely inspect the work when it is being put in, but they go to a man's building at odd times and look all over his wiring again, and if they find any such foolishness as copper wire replacing fuses they will very often order his lights to be taken out; and it has only taken one or two instances of that kind to awaken the public to the fact that there are rights which the central station has and there are certain precautions which they themselves must take.

The third great branch, and the one with which we more particularly concern ourselves to-day, is comparatively a new one, but has in the short time it has been in existence had so phenomenal a growth that it is no wonder that we find even the commonest precautions oftentimes neglected in its use.

In the "alternating" or "converter" system we may say at once, as regards the secondary distribution, *i. e.*, from the converter to the lamp, that the rules already laid down for the installation of low tension direct current wires will practically cover the case. The alternating current of fifty volts, which practically is the standard to-day, will work successfully with insulation, and under conditions which would lead to trouble immediately with even the one hundred volts direct current; and this fact in itself often leads to poor work, either from intention or ignorance. The wiring, of course, must be proportionately heavier for this current than for the direct, which perhaps adds some slight risk of under-sized wire being used; but this is an evil which will generally correct itself, owing to the diminution in light, making itself felt before the danger point is reached. The fact also that the converter cuts off all connection between the customer and the company removes the great danger of grounds on one building affecting the whole system.

There are certain peculiar features, however, which should not be overlooked, namely, that moisture will often cause sufficient leak in the way of a short circuit to heavily overload the wires, while not sufficient to start the "dead" short circuit, which would blow the fuses. For this reason special care should be taken that the wires are properly "fused," and that in the event of a fuse persistently blowing with only its proper number of lamps, search should be made for leaks.

The general tendency in electric light business being now very largely to make the consumer responsible for all the wire upon his own premises beyond the converter, narrows the subject down to that on which I wish more particulurly to speak, namely, "High tension alternating current distribution." This current has to a certain extent the governing characteristics of both those mentioned above, and this has excited a disproportionate fear of it. Its tension of 1,000 volts (to take that oftenest used) is high enough to make a first-class insulation necessary as a precaution against leaks, which may soon break out altogether, and its being a constant potential system allows the whole power of the dynamo, or rather of the engine driving it, to be possibly developed at any point by a short circuit.

Without going into the fiercely debated question of direct *vs.* alternating currents, I would call attention to one fact. With high tension direct currents I have seen linemen, in repairing lines or cutting in circuits, handle an arc circuit of perhaps 2,000 volts when they should hardly touch it, and by taking a quick hold and keeping it, make a connection while really in a position of great danger, since a ground coming on the line elsewhere would surely kill or injure them, though they would not believe this, since they could only feel the current at the moment of taking hold or letting go. With the alternating, however, the effect is constant, and so intensely disagreeable that a very slight leak indeed will discourage any one from running the least risk on live circuits. I may mention in this connection that as far as my experience goes (and I believe some of the learned doctors agree with me) the action of a heavy shock of alternating current is to force the diaphragm up into the chest, compressing the lungs, and literally squeezing the breath out of one, causing the cry which seems peculiar to those caught in this way. If the person is stunned, dash cold water on the face and chest, loosen the clothing, especially at the neck, and use artificial respiration as for the drowned. One of our linemen who was badly caught, was brought round by these means, after being to all intents and purposes dead for nearly ten minutes, no breath or pulse being discernible.

Coming now to my subject proper, the first precaution which I think we should take in any case, is to properly lay out a system of distribution according to the circumstances of the installation. Almost the first point to be thoroughly settled is the size of unit dynamo which it is proposed to use. This should be kept as large as possible, for the reason that practically a large dynamo takes no more care to look after it than a small one, while at the same time care must be taken not to get it too large, since an underloaded dynamo and engine is not economical to run.

---

[1] Paper read before the National Electric Light Association at Providence, R. I.

The second point is that as alternating current dynamos are easiest run separately and not in multiple arc, the planning of the pole lines, feeders and mains for the various circuits should be such that these units can be economically used.

Another point to be looked at in the general plan is, that, wherever possible, the sizes of the mains and feeders should be kept the same throughout, thus reducing the number of sizes of wire used in street work, and keeping the pole lines and fittings as uniform as possible. It is astonishing how few different sizes of wire are really needed if care be used in planning, for it is always a good fault to keep the sizes up, both for mechanical and electrical reasons. It must not be forgotten that, however much we may be able at the present, or have been able in the past, to control the condition under which we shall supply the public with any article, it is only a question of time when the public will decide for themselves, not only under what conditions, but in what quantities and at what prices, they will take what we have to supply.

In the early history of electric lighting, and, we may say even to the present time as far as arc lighting is concerned, the contract basis will be the one upon which the light is sold. With incandescent lighting, for many years, the contract system seemed to be the basis, but as soon as a good and reliable meter was placed upon the market, that moment the conditions were changed.

It is a part of human nature to desire only to pay for that which we use, and it is equally a part of our human nature to try and get something which we have not paid for, and for this reason there will always be those who desire the meter system and those who desire the contract system. but the weight of public opinion is so heavily in favor of the meter system that we may, to all intents and purposes, consider it as the adopted method of sale. Electric lighting is, after all, only a lighting business, and those who are concerned in the furnishing of incandescent electric lights will learn many a valuable lesson from the gas companies, who, as I have more than once reminded you at these Conventions, did not reach their present methods and conditions by having them schemed out at the start, but through much tribulation and many trials, so that their present methods are simply another instance of the survival of the fittest. For these reasons in deciding on unit sizes remember to count on probable load and not on probable number of lights rented.

To begin with the dynamos, we may say that the best unit to use will probably be found by taking the maximum all-day load. In some cases, however, this will be very light, compared to the loads thrown on during the "heavy hours," and in such cases it may be better to use a much larger machine for the sake of uniformity with its many advantages. If multiples of a unit are used, only one or two spare parts need be carried; the feeders and mains can be all laid out alike, and any dynamo is ready to take the place of any other without any preliminary cutting and changing of circuits.

The question of subdivided power is a vexed one, and one on which we can never hope to see all agreed, and I therefore do not make any suggestions beyond noting that a dynamo which can pull up its driving engine without injury to itself is a good thing; that running a small engine as a relay is cheaper than running a large one, and that, in incandescent lighting, the customer, not the central station, regulates the load. Of course, these remarks apply only to engines of the same type. I do not set a small high speed single expansion engine against a large compound or triple expansion one.

Keep dynamos well insulated, but put collectors to lead off static electricity from the belts. If there is a slight leak on one of your circuits, the easiest path for the spark may be to jump into the armature and so to line and ground, and this spark will punch through almost any insulation, and gradually keep making it weaker till some day the current generated in the armature follows the spark and your armature is gone. Look carefully to all screws and bolts; the alternating current seems to have some peculiar effect (perhaps by mechanical vibration, perhaps by actual molecular expansion and contraction) in loosening screws, causing small arcs which may melt off connections, or may make bad contacts. Nothing is more annoying than to have a dynamo operating perfectly until shut down, and then refusing to start up again. This comes often from such poor contacts—the current following and bridging over as long as it is kept going, but failing to make the first jump necessary to start. In arc lighting machinery this used to be got over by "jumping the machine," or short-circuiting it for an instant; and I have known alternating incandescent dynamos ruined by being served the same way.

A small air pump and tank with lines of pipe through the station and a hose to direct a strong jet of air into the armatures will be found a valuable addition to station equipment, and the amount of dust and copper which can be blown out after the hand bellows has done its best, is surprising.

Have your switch-board so that circuits and dynamos can be easily and quickly changed.

One feature which Ferranti seems to have early foreseen, and that is a feature which in our American practice I think has been somewhat neglected, is the use of fuses with a very much greater distance between the points of attachment, and some ready means of replacing the fuses without danger to the person so doing, even if a short circuit should still exist on the line which is being handled.

For this reason also, it is a great mistake to crowd switchboards too closely. There could be abundant room given both for the operator to stand in front of the board and to beat a hasty retreat without the danger of being caught by machinery or belts behind him, and to allow the free use of the hands and arms without the danger of being burnt by fuses in the immediate neighborhood which may go off at any time. While an alternating current will not make much of an arc when a fuse melts simply from overload, it does make a wicked and demoralizing one when a short circuit is present, especially when it has a heavy machine behind it.

There will always be some hesitation, I think, as to the adoption of devices for putting in fuses which do not have a positive contact, such as a screw connection, or one which I think Ferranti used, a plug which can be twisted in at every application, thereby keeping the contacts clean. I think, however, that we shall soon see a fuse adopted which shall be in the form of a switch which can be opened and closed as often as needed, to keep the contacts bright and clean.

In fitting up the fuse blocks and switch boards it is well to leave no points or sharp corners exposed, since the alternating current will jump from such points if it be trained across or induced to do so by the presence of the lead vapor from a fuse which has blown.

It was one of my earliest experiences to see an arc jump in this way, from the ends of wire which had been pushed so far through the connections on switches as to show their ragged points beyond the metal of the switch. The arc, which was formed on a blowing out of high tension fuse, bridged between two such points a distance of nearly ten inches and held there for some fifteen or twenty seconds, in which time it had pretty thoroughly melted up the brass parts of the switches. In this case the arc had been started by throwing in a 100,000 watt dynamo on a short circuit.

While high insulation is needed on a switch-board, which leads many to the use of rubber wire, I would say that I think a far greater danger is introduced by its use, namely, fire. On an incandescent board, fuses may go at any moment and draw a heavy arc with them. If coverings and fittings be used which will not carry flame, all is clear for new fuses in a few seconds; but if once fire starts and the other fuses let go, there is no saying where the damage will stop. While the voltage was enormously higher, and we do not know under how much more difficult conditions they labored, the destruction of a switch-board in the Grosvenor Gallery station in London, and the consequent shutting down of 30,000 lights, is a warning which all should heed.

It is always best not to have wires concealed anywhere about a station, and they should be run on porcelain or glass insulators so as to be perfectly safe from fire, even if they should be soaking wet. With wires running this way there need be no fear of throwing water on wood work which is in danger of catching fire, since the worst damage that can be done would be the blowing of the fuses from a short circuit. Of course, the covering of the wires should be of a kind which will properly protect those who are working among them. A separate ammeter and voltmeter on each circuit or feeder, while apparently an expensive luxury, is in reality a very great saving and convenience in a station which has lines over a half mile in length. The ammeter enables one to tell precisely on what feeders the load is heaviest; and where more than one feeder runs to any district it is a convenient means of knowing just upon what circuit to cut in the lights for any new customer. If the system in use allows any compensating device for indicating the correct voltage at the point of distribution, instead of in the station, it will be so much the better; and also to have on all feeders, if possible, but certainly on extended ones, some arrangement for raising the electromotive force in order that both short and long feeders may be operated from the same dynamo. Of course, there are many cases where it pays to run a separate dynamo at higher voltage for a particular feeder or set of feeders on which there is a heavy drop. But even in such cases it is often useful to be able to run these feeders with those on which the drop is small from the same dynamo.

Put pilot lamps on each feeder, which will often attract attention to a circuit being out, quicker than the voltmeter; and put pilot lamps also on each field circuit. If separately excited dynamos are used, put pilot lamps also on both the main circuit and field circuit of the exciters. These pilot lamps need not, of course, be up to candle power. High resistance lamps or lamps placed in series will be quite sufficient, and the amount of current they use inappreciable, while the saving in time which the lamps afford in case of any failure of current, by enabling an attendant to locate the trouble at once between certain points, is often considerable. Thus, if the pilot lamps on the main feeder and on the field circuit of the alternator have both gone out while the pilot lamps on the exciter mains and exciter field are still lit, it shows that the trouble is somewhere between the pilot lamps on the field circuit and the exciter mains, being probably loose contacts in the switches, or something of that kind. If the pilot lamps of the alternator only have gone out there is no use looking for any trouble about the fields or the exciter circuits, since, the pilot lamps being lit there, shows at once that the trouble is further on in the chain of connections. It may seem a refinement to put in such arrangements for the sake of saving a few minutes or even seconds, in locating troubles; but it must be remembered that the public are more and more demanding that incandescent lighting shall be as continuous and reliable as any other method, and when all the lights in a building go out at once, a few seconds delay may be a very serious matter. The public are not concerned with what the cause of the trouble may be, but only have one question, "Why do I not get the light that I pay for," and the man who rents one light is often more troublesome than the man who rents a thousand.

Separate exciting I think will be found to give the easiest handling of dynamos, and also has the advantage that as long as the alternators each have their independent rheostat, the regulation of the exciting current regulates all the lights with very little trouble.

For small stations self-exciting machines have their advantage since it gives less actual machines to look after; but I doubt whether this advantage is not more than covered by the fact that it is a simple matter to carry a spare armature for the small exciter, which can be slipped out in a few minutes, rather than to have to change the heavy armature of an alternator because of some slight trouble with its exciting coils or commutator.

While alternating current dynamos are best run separately, and the need of synchronizing is not often felt, when it is wanted, it is wanted badly; and it is a good plan to carefully speed all machines and engines so that they will all run at one speed when light, and at a certain increased speed when loaded. This can generally be done with separate engines by changing the governors, and where shafting is used, by slight changes in pulley diameters, and this will enable the dynamos to be run together, if required, with as little trouble or danger as may be.

The keeping of a careful log in boiler, engine and dynamo rooms I need hardly refer to; for some years now in the larger and better equipped stations it has been customary to weigh the coal used under the boilers and to keep an hourly or half-hourly record of the load upon each dynamo and feeder. Now, that reliable meters can be had for use on high tension circuits, I think it would be a matter of the greatest importance to have one of these meters placed in the circuit of each separate feeder, since by that means we are enabled to check up the difference between the amount of current furnished to the feeder at the station each month, and the amount of current which is charged to the various customers on that same feeder. There is nothing more than the station meter of the gas company and its value as a means of detecting leakage on the lines, whether from bad insulation or from theft of current, cannot be over-estimated.

One point we must always keep clearly before us and that is, that as long as the contract condition of selling light existed, the cost of making this light did not bear so unvariable and fixed a value with reference to the profits of the station as it does where a meter was used.

With the contract system there might be many contracts made for the use of a certain amount of light, which amount of light would not be used, resulting in a direct profit to the company; which in such cases received money for what it did not furnish, but with the meter system the only receipts of the company are for the current which is delivered to the customer and the difference in the price charged to the customer per watt hour, and the cost of producing this current per watt hour is the measure of success or failure.

It is, I suppose, hardly necessary to refer to the advantages of keeping careful records of dynamos and converters and all repairs to same. The advantage of such a system of records can only be appreciated by those who have used it. There are certain classes of machine in which armatures will last without giving a sign of trouble for from two to three years, and then one coil after another will commence giving out. It may be found that when a machine has been running for perhaps a few months and a coil gives away, that this coil may have given out from some local defect or injury in itself, and it will be worth while to repair only this coil. On the other hand, if at the end of four years a coil gives out, and then a month or two later another coil, it may pay better to rewind the whole armature, rather than to do any patching, since the chances are that the whole armature is weakened and will keep on breaking down until the whole has been rewound anyhow. The same with converters—there will occasionally be found a converter which is always in trouble. It may keep blowing fuses or burning out switch-boards continuously, and in a short time the extra cost of taking care of it would soon amount to more than a complete repair.

I do not mean to include in the regular repair book such small items as the placing of fuses; but it is astonishing how much can be learned about converters by persistently following them up. The meters which are now in general use cannot be too carefully watched. There are numerous little troubles which arise with them, chiefly from poor contacts and dust. By keeping a careful record of the readings of each meter from month to month a great deal may be learned about them, and some of the apparently unaccountable changes in their records traced up.

Among some of the minor points which must be looked out for are just to see that spiders and insects do not get into them and stop their motion; and,

Secondly, that the growth of electrical knowledge among the customers does not lead them to try to beat the meter. We have found cases where this was done by drilling a very fine hole in the case of the meter and dropping into it a fine wire, which should touch the vanes and so stop the meter recording, this being done for perhaps two weeks in the month, so as not to arouse suspicion by a total cessation of the record, while at the same time allowing a wide interval of time during which the meter inspector might call without detecting the presence of this wire.

The short circuiting of a meter has been practiced to some extent, but this can usually be guarded against by running both wires to the meter under mouldings, which as a rule the customer does not care to meddle with. In one type of meter we have seen large pieces of iron placed beside it to interfere with its record, and this will affect, I believe, almost any mechanical meter. The electric meter, being as a rule placed, like its cousin, the gas meter, in the darkest and most inaccessible spot in the building, is not always easy to keep closely watched, but if it is, a few good examples will often do away with a large measure of the trouble.

To take up the second great branch of my subject, that of the "Outside Distribution," let us return to the point where we spoke of the importance of outlining the plan and lay-out of the circuits, in connection with the decision as to the size of unit dynamo.

For the outside distribution, the first point that we have to consider is the question as to whether the wires are to be run overhead or undergrouud. Without expressing any preference for one or the other, I would mention a few points in each which should be most carefully looked after, before deciding upon the use of either. If underground work be possible, what advantage do we gain by its use? We may say that we practically get rid of all the trouble connected with storms and fire and other incidents of like nature. We also remove a great deal of the public clamor against the use of electricity, and we avoid the annoying interruption to work which goes on from the mere fact that our operations have to be conducted in full sight on the public streets. We also, to a certain extent, get a kind of claim upon premises where the current has been introduced underground, since, as a rule, the connections are not visible from the outside; and when the current has been cut off we are not required to remove them, as is often the case with overhead wires. All things considered, the maintenance of underground cables would probably be less than that of overhead wires, providing that the fixed charges due to the enormously increased cost be left out, since accidents to overhead lines generally occur together, from storms, etc., compelling the carrying of a larger force of wiremen, or a proportionately longer time to make repairs.

The greatest disadvantages of underground wires are undoubtedly the uncertainty as to their life, both from want of experience and from ignorance of the exact causes which lead to their destruction; and also that their enormous first-cost raises the cost of the production of the electric light to a point which compels us to charge the public more for their light than they are inclined to give, which fact in many cases actually prohibits its introduction. A very peculiar series of phenomena are introduced when wires are placed underground in such close proximity to one another, as they necessarily must, where a large number are run in conduits together, and these results are not very well understood so far even by those who have had the most experience with them. I may cite as an instance of this, the effect which has been observed in Mr. Ferranti's 10,000 volt mains from the Deptford station, where the electromotive force at the London end is higher than that at the generating station. There seems to be some doubt as to what causes this condition, and so far some controversy over it; though it would appear from recent utterances to be fairly well proved that it is due to static capacity, one thing seems certain, that a similar effect has been observed on some overhead lines; but in the latter case it has not been sufficient to interfere with good running.

If the overhead system be determined upon, nothing but the very best construction should be used. It must not be forgotten that the majority of accidents which have occurred from overhead wires have nearly all been caused by poor construction. I do not think I am far wrong if I say that all accidents which have occurred to others than employees of the companies have been caused either by poor construction or gross carelessness on the part of those injured. With employees the case is somewhat different. Undoubtedly many have been killed by their own carelessness, but there is a certain class of accidents which occur to the most skilled men and under the most extraordinary conditions, which must be put down simply as true "accidents," and against which no better provision can be made than by careful construction and inspection.

I think if I detailed the method which was followed in laying out the feeders for a large central station, a modification of this will probably be found applicable in most cases.

The bulk of the lighting was expected to be on two main streets of the town running parallel with one another on a long curve for about a mile and a half, and the central station was located about halfway between the centre and end of this line, and about one-half mile distant from the nearest of the two streets. There were five cross streets available, running from the central station in almost a straight line to different points of the main lighting district, and the question was raised as to which would be the best to use for running the main feeders. Approximate calculations showed that the full load of the largest machine proposed, 3,000 lights, could be carried between any two of these cross streets or feeder junctions with the maximum drop proposed, if No. 3 wire were used for the mains. It was therefore decided to use No. 3 wire continuous from end to end for the mains to start with, proper arrangements being made to cut this main into sections as fast as the load should increase so as to render the splitting up of the load on to one or more machines necessary.

To determine the size of feeders the only point raised was as to which was the heaviest wire which could be run upon poles and handled easily. It was determined that No. 0 Brown & Sharpe would best fill the conditions, and five lines of No. 0 Brown & Sharpe wire, one on each street, were run up and tapped into the mains at the junctions of both streets. The maximum number of amperes that could be carried by each feeder with 2% loss was then calculated and marked on the feeder at the switch-board and on the plans, thus: No. 1 feeder being the longest would only carry 22 amperes; No. 2 feeder would carry 40 amperes; No. 3 feeder would carry 80 amperes; No. 4 feeder would carry 65 amperes, and No. 5 feeder would carry 30 amperes. These would all run the one switch-board, and as soon as the ammeter on any one of these feeders showed that the maximum load during the nights run reached its limit a second No. 0 wire would be run on this pole line and multiplied with the first, doubling the capacity of the feeder at once. In the same way, as long as the total load on all the feeders did not reach above the first 3,000 light machine installed the mains were left continuous; but as soon as this limit was reached the mains were cut at such a point as to about divide the load into two (2) parts, and two machines were started.

This progress will be kept up indefinitely, the feeders being always kept below 2% loss and the mains cut to accommodate the unit of 3,000 lights of dynamo capacity.

The feeder which had the smallest available load, No. 1, carrying 22 amperes, happens to be the feeder which runs to the district where the fewest lights are expected, and in all probability will never be doubled up, the district being thinly populated and with no immediate prospect of its being built up very much.

In this plant another detail was introduced of making the breaks in the mains by means of switches, so that in the event of a breakdown of a feeder-line the closing of these switches would enable the lights to be taken care of by the machine on either side.

The plan in fact makes the whole system of mains one large switch-board, allowing for the transfer of lights up and down the line among the different sections.

In laying out long feeders, try and keep those which belong to different circuits as far apart as possible, since wires which run parallel with each other for long distances will cause interference, especially if the voltage of one circuit be considerably higher than that of the other, and still more if the static capacity of one be much larger. In putting in new lines be very careful to avoid the effects of induction from live circuits which sometimes rises to an unexpected degree. I have known of a case where men received a heavy enough shock to throw them down in taking hold of the bare end of a wire totally disconnected in every way from the circuit, but which ran parallel for about a half mile with a 1,000 volt feeder. Had these men been handling a bare end on an iron pole they might have received shock enough to throw them down, and injure them seriously from the fall, when we should have had another "mysterious accident" with electricity. In placing converters, while in many cases they can be placed with perfect safety inside of buildings, they can generally be placed outside in positions where they can be got at easily for re-fusing, and without disfiguring the buildings to any extent. A very good rule is to allow no porcelain insulators on out-door work; nothing but glass put on iron brackets, so made that the glass can always stand upright to prevent filling with water. No loops should be allowed to be cut in on the circuits between poles, but all connections should be made at a pole. And in the case of converters placed inside buildings, a double pole switch should be placed at this point, though I should not think it absolutely necessary in the case of converters placed outside of buildings.

Run converters separately as much as possible, and if it is absolutely necessary to run them in multiple arc keep a close watch upon the fuses, since, when run in this way, converters have a trick of blowing fuses without any apparent cause. Never change high tension fuses.

When converters are brought back to the station for storage they should be kept in a warm, dry room to prevent the condensation of moisture on the interior of the cases, which will damage them quicker than leaving them in service out of doors.

It must not be forgotten that the thoroughly sound overhead construction is the strongest argument which can be advanced to-day against companies being compelled to spend large sums of money on underground work. I have been so much interested in the pole-line work done in this city that I have examined it with some little care, and I find some points that surprise me, though I was well aware that their construction was of the best, and I relate some of these points for your consideration. All new poles are made of sawed yellow pine tarred, were sunk in the ground and painted above it, no less than 8″ square being used anywhere and the majority being 10″ and 12″.

The cross-arms are not only heavy in themselves but are rendered even more so by the kind of pins used. These are not of wood, but are made by placing a bolt with its head in the glass insulator and cementing it in solid with plaster of paris; these lag bolts being then bolted directly through the cross arms, avoiding the weakening of the arms by large holes bored into them and doing away with snapping pins.

All new wire strung is of high grade insulation, and all low grade wires whenever taken down are re-insulated with high grade insulation before being replaced. All joints in the line are soldered, and nothing but iron brackets and glass insulators allowed for outside work. Not only have the iron brackets been made for all situations, but they have been made in pairs so that the leading wires shall always be kept a uniform distance apart, which adds enormously to the trim and workmanlike appearance of the lines. I think all will agree with me that those who are willing to spend the enormous sums that such work costs have established a right to ask that they be not expected to do anything in the way of underground work until underground work has been demonstrated as successful in every way as the work that they have done here; and more than this, that such underground work shall possess decided advantages to compensate for the increased difficulty of locating and correcting trouble, in which respect the overhead line is undoubtedly far superior.

If municipalities wish to place themselves in the front rank of progress and at the same time encourage local industries, let them rather expend their energies in insisting on and compelling the proper carrying out of well-tested methods of construction rather than in demanding that untried principles and methods be experimented with, often under conditions which preclude their success.

ON ELECTRICAL MEASURING INSTRUMENTS, AND THEIR METHODS OF USE AND CARE.[1]

BY EDWARD WESTON.

IN 1881 to 1882 a proposition to place a voltmeter of excellence or ammeter of excellence in every plant or in connection with every dynamo, as was suggested here to-day by Mr. Smith, in his paper, would have been met very largely by ridicule. That was not the fault of the users as much as it was, probably, of the people who were engaged in pushing forward the commercial end of the business. The users could not be expected to understand that matter or to appreciate that if they did not use such appliances it meant considerable loss in the end.

Every instrument has its peculiarity. To speak of them generally you will find that all of them have their defects and all of them have their merits. They must all be used properly under certain conditions, in order to yield certain and accurate results. The voltmeter of the Cardew type, which is supposed to be a very permanent form of voltmeter for use with alternating or direct currents, is so extremely sensitive to changes in temperature from external sources as to make quite a perceptible error and one which would in the end cause a station considerable loss. If any one would like to satisfy himself about that, let him place such an instrument in circuit near a window through which the sun is shining, shield it from the sun's rays, turn the current on, observing the reading. Let the sun's rays fall on the tube and notice the change. I think most of you will be considerably surprised to find that the percentage of change is very large, even under those conditions. The Cardew instrument, properly used, will yield excellent results. It should not, of course, if accurate readings are desired, be placed in a vertical position. The index moves too much, and I believe you all fully realize the fact that a volt or two volts additional on an incandescent lamp enormously shortens its lifetime besides adding largely to your coal bills.

In direct current instruments it will be supposed by many persons that, because many contain no permanent magnet, their readings are not affected by their proximity to a dynamo, but that is not so. It is a very easy matter to ascertain how much their readings are affected under different conditions, but you will find that they are very seriously affected, and, in general, no instrument that is being used for the purpose of making an accurate determination should be placed near any disturbing force, either conductors carrying powerful currents or other magnetic fields, and hence this should be strictly avoided. The Cardew is less affected in that respect than some others, but it is not entirely free from that difficulty either. Those instruments that are least affected are instruments of the zero type; that is to say, where you balance a known electromotive force against the unknown electromotive force by means of a rheostat, using the potentiometer method. Those are less liable to be affected than any of the so-called direct reading instruments, but they also are affected, and their sensibility is reduced. In making readings they should never be placed very near dynamos.

---

[1] Address delivered before the National Electric Light Association, Feb. 19, 1891.

Permanent magnet types of instruments which have certain very desirable qualities for general use in direct current measurements should never be taken very close to dynamos. If the magnets are properly made and the magnetic construction is good you may trust permanent magnet instruments implicity for years, providing they are used with due care. The most careful examination has revealed the fact that after three years continuous use the change has amounted to less than one-tenth of one per cent. Now how is that secured and how is it maintained? It is secured, in the first place, by very careful selection of the steel and very careful artificial aging and also in the design of the instrument.

They should not be used roughly by any means; they should be carried with extreme care and not very much jarred, because the jarring, while it does not affect the magnet at all, is likely to damage the pivots or jewels which carry the moving parts and so introduce the element of friction. This element of friction is a very serious thing in a very large number of instruments. In some the error will amount to three or four per cent.; in others it is much less.

In voltmeters there is another source of error which should be looked after particularly in some forms of instruments, very carefully. Voltmeters whose coils are wound with copper, unless they have compensators or some device for compensating for the change in the temperature of the copper are not reliable instruments to use for station work. It is commonly known, of course, that the coefficient of error of temperature is very large for copper; it amounts to about one per cent. for every five degrees Fahrenheit. Therefore a change of twenty degrees introduces an error in such instruments of about four per cent.; a larger change of course introduces an error correspondingly greater. German silver does that to a less degree of course. But even there there are serious difficulties to be met with in getting an instrument which, with a low temperature coefficient, will not heat too much by the passage of the current. So that no instrument should be sent out as a standard voltmeter, or as a voltmeter to check other voltmeters, without an absolute statement of its temperature error and some means of providing for its ascertainment. It does not suffice to notice the temperature of the surrounding air, because the temperature of the coils inside the instrument may be very different from that of the surrounding air, especially after the instrument has been in circuit a short time. The way in which electricity acts is so well understood that all those cases have been pretty well worked out, but in getting accuracy in the instruments there is a great deal to be done. Some years ago I had the good fortune to discover an alloy in which the temperature coefficient was practically nothing. We have used that to some extent—not to the extent that I should like to see it used and expect to use it later on. That alloy has given us a great deal of trouble in working. We have had to learn how to work it and I do not think we fully understand it yet; but when we get it in shape, then the temperature error will be practically entirely eliminated. How near we have approached this elimination you can judge when I tell you that in our ordinary standard voltmeters—I do not speak of the ammeter—the changes are less than one quarter of one per cent. for thirty-five degree Fahrenheit.

The type of instrument we have put on the market we never intended for switch-board use. It was intended as an absolute standard to be kept with care for checking other cheaper forms of instruments for general use. As a matter of fact no one meter, strictly speaking, exactly meets the requirements of central station work. The index does not move far enough to enable you to see the minute changes—apparently minute changes— at any reasonable distance from the instrument itself. An instrument for station work should have a very large movement for a single volt, so that a man can see such a change across the room quite readily. There have been some instruments of that type put upon the market; some had very good qualities; unfortunately some had very bad qualities. There has not been any complete solution, I think, of that problem. The nearest approach to it were two instruments, one made by the United States Company, the other by the Edison Company. Both forms had serious objections. The one did not remain constant; the other did remain, but it was a very delicate instrument and after being in a station was more or less affected, in fact considerably affected, by external influences. That problem remains to be solved, so to speak, yet, *i. e.*, to produce a satisfactory volt indicator with a very wide range for a very small change.

Ammeters are, of course, of less consequence. There is not so much loss due to change of currents as when you have the voltage changing; your lamps do not suffer quite as much. Ammeters are based, of course, upon the same general principles as voltmeters. The forms of them are too numerous, almost, to mention, and too well known to need describing. Some new forms have recently been brought out which I think, on test, will be found to be very excellent. In a station ammeter you should have at least this one element, that it should not be affected even by the most intense fields, because it has got to be placed very close to the main conductors on the switch-board. It will be of very great importance, much greater importance later on than it is now, when more machines are coupled in multiple arc, especially when alternating current machines are coupled in multiple arc. The load that each machine carries should be pretty fairly distributed amongst the various machines. To insure that, good instruments must, of course, be used. Any instrument which is seriously affected by external fields does not exactly meet the requirements of the art. Furthermore its indications should be prompt, positive —not slow in coming to rest—and always moving naturally to the same position from the same current strength and with very little magnetic lag.

Most commercial forms of ammeters, of course, are based on the action of a coil upon a mass of iron. A great many of them have a very large amount of lag. Some of them I have found with upwards of fourteen or fifteen per cent. lag put out with endorsements, and endorsements sometimes of very high authorities, as to their excellence and general accuracy. Tests show them to be just the contrary.

The ammeter question with permanent magnets is a much more serious matter to deal with than the voltmeter, and of course any permanent magnet would not do at all for alternating current work. A really portable form of alternating current instrument, similar in general character to the portable form of direct current instruments, capable of being read directly, is a very great necessity, and I think will be supplied in a very short time. Practically it is now an instrument that could be carried around with the same degree of comfort that you carry a direct current instrument.

REPORT OF THE COMMITTEE ON DATA.[1]

A. J. DE CAMP, CHAIRMAN.

THE report of the committee will be printed in two sections. Part I. will treat of the subject of "The Dangers of Electricity," growing out of the action taken at the Twelfth Convention on the paper presented on this subject by President Henry Morton, of the Stevens Institute of Technology. Part II. will treat of the subject "Standards of Economy in the Generation of Power," growing out of the action taken at the Twelfth Convention on the paper presented on this subject by Mr. H. M. Swetland, editor of *Power*, New York. Mr. Swetland has kindly consented to assist this committee by preparing this section of the report, and to present it in person:

PART I.—THE DANGERS OF ELECTRICITY.

Conforming to the instructions given to it by the Twelfth Convention, two circulars of inquiry were prepared and sent out from the office of the association to all central station companies in the United States for the purpose of collecting the statistics as desired. These circulars will be printed in the appendix of the Volume of Proceedings for this convention.

Replies to the inquiries regarding personal injuries to workmen employed by central station companies have been received from 213 companies. Of this number 45 companies failed to state the number of workmen employed, but report no accidents. 168 companies, employing 1,233 men, report 7 accidents. This report covers the year 1890. It shows that in doing 369,900 days' work but 7 injuries occurred. None of these injuries were fatal.

In the matter of fire losses, no data have been collected. I am desirous, however, to lay before the Association an extract from a report made recently by William McDevitt, chief inspector of the city of Philadelphia. It is as follows:

PHILADELPHIA FIRE UNDERWRITERS' ASSOCIATION,

136-138 South Fourth Street, Philadelphia.

Electrical Department.

There are over 5,000 buildings in Philadelphia wherein electric currents are used for light and power purposes. Of this number 287 buildings (7 of which are dwellings) have their own apparatus, the latter varying in size from a 20 light to one of 4,000 lights. The number of lights furnished by these private plants aggregate 80,258 incandescent and 3,325 arc lights. One retail store contains 482 arc lights.

There are 15 public stations distributing electric currents to all sections of the city, furnishing thousands of lights and power to dwellings, churches and other classes of buildings. The number of lights supplied by these respective stations vary from the very small station furnishing 2,000, to the Edison, which furnishes over 40,000 incandescent lights and current for a large number of motors. The electric motors in use are of a capacity ranging from ½ to 30 h. p., being used to a great extent as a substitute for laborious hand or foot power in dwellings and small workshops, and are being rapidly introduced as a more ready motor in place of steam and hydraulic power in propelling machinery.

---

[1] Read before the National Electric Light Association, at Providence, R. I.

All of the different systems of electric lighting invented are, or have been, given opportunity to operate their respective apparatus in our city, and, wherever consistent with safety, approvals were given for use in insured buildings. In innumerable instances, where no insurance was held on buildings, when electric lighting was introduced, contractors were required to install the work in accordance with the Underwriters' requirements and subject to the approval of the latter's inspection.

No insurance loss occurred in any building in our city during the past year from fire where the cause could in any way be attributed to electric wires. The education of the workmen is the new factor, and the steady improvements made in materials and devices in electric appliances, have materially lessened the danger in its introduction; but a like knowledge of the inherent danger in the use and handling of electric light appliances should be had with consumers or users.

Experience has proven that no perfect insulation can be maintained with the customary method of installing electric wires, where either the conductors or the covering are exposed to mechanical injury or deterioration from affecting influences that may arise, more especially when wires are concealed in inaccessible places.

In the matter of injuries to firemen from electric current and fires caused by the same, returns made to the United States Census Office from chiefs of fire departments show the following:

TABLE IV.

Returns from chiefs of fire departments, showing number of fires and injuries to firemen caused by electric currents, compared with other similar data. For the year 1890.

Total number of towns reporting	367
" " regularly employed force	16,143
" " enrolled volunteer force	35,510
" " alarms calling out whole or part of force	30,862
" " fires caused by electric currents	363
" " injuries received while on duty	1,303
" " " " " at fires caused by electric currents	26
" " injuries caused by electric currents	25
" " fatal injuries	55
" " fatal injuries caused by electric currents	1
" " deaths from natural causes	358
" " towns in which firemen are supplied with printed rules for the prevention of injuries	1
" " towns having an electric fire alarm system	195

PART II.—ON COMPARISON OF ECONOMY IN THE GENERATION OF POWER.

The object of this work has been previously set forth in a very plain and comprehensive manner, but it may be briefly alluded to here, not only to emphasize its importance, but to enlist the earnest co-operation of the members of this Association. The committee have undertaken to record the actual cost, in towns, of coal of a definite amount of horse power actually delivered, *i. e.*, work actually performed represented by amount of electric current actually delivered, recording the results obtained from all ordinary types of equipment in use for the generation of power, more especially steam power; the idea being to show, not only the difference between the results obtained from the more modern and complete installations and those less favored in equipment, but to record the varying results obtained from each varying type of equipment under different management, making the comparison of coal with coal, boiler with boiler, engine with engine, type with type, and appliance with appliance.

These records will enable the manager of an electric plant having an ordinary equipment to compare his results with those plants operated under exactly similar conditions. To this end an inquiry circular was sent to all the central stations in the United States.

The questions asked for definite data: First, as to equipment, and second, for information regarding the time and amount of fuel required to generate a definite amount of horse power. The call has been responded to liberally by the different companies, something over four hundred returns having been received up to date, from which the foundation of this work has been fairly started, and the compilation of data received has been commenced.

Arrangements have also been made to obtain data relative to the economic generation of power in other branches of manufacturing. Results obtained in the engine room of the cotton mill, the rolling mill and various other industries, together with their special equipment, will be recorded for the benefit of comparison with the results obtained from similar equipment in electric lighting. 500 circulars to leading manufacturers have brought out a ready response, and we must confess these returns show an elaboration of detail and a conciseness of calculation which prove that the question of economy in the generation of power is not a new one to manufacturers.

The returns from the central stations are the best evidence that could be offered as an argument in favor of this work, for while many of the returns are complete, proving that a faithful record of the cost of the required power is at the disposal of the manager, a larger number of them report no tests made, or no records kept, and in several instances the whole quota of questions was answered by the very expressive and comprehensive statement, "Never mind the cost of power, we are paying dividends." Those sending complete reports often accompanied the returns with a letter of inquiry as to what others were doing with a similar equipment, expressing marked interest in the work of the committee and asking for a copy of the report when completed, and we predict that future reports from a "no data, but dividend-paying" element of these returns will in the near future withdraw their statement regarding dividends and report themselves as doing less business, or out of business, having failed to meet successfully the competition of the manager who knows what power costs and sells electric current at a fair margin of profit on that basis.

In a very few instances only, were all the questions in the circular answered. The evaporation of water per pound of coal was stated in only 21 reports. In a less number of instances was the percentage of entrained water stated, and the question relative to the number of pounds of steam used per horse power was often considered altogether too intricate and far-reaching.

Now, while answers to these questions are imperative to successfully compare appliance with appliance, all these reports which gave work performed and fuel actually consumed were useful and formed a basis of a good beginning. The main idea of the inquiry circular was, however, often lost sight of or ignored, and the question of the amount of coal used, or its reciprocal question, relative to the work performed, left unanswered, while nearly all the other questions were answered in full. However, as has been stated, sufficient data have been received to furnish the foundation of this work, and more than enough to satisfy the most sceptical of the absolute necessity of these records.

If the business of electric lighting is to be successfully conducted, a fair basis of first cost of power must be made the basis of charge for the service rendered, and if one horse power can be generated for one hour by burning one and one-half pounds of coal, the consumer of electric light will not long be satisfied to pay a profit to that electric plant whose management is satisfied to burn ten pounds of fuel for this same horse power.

The reports received in many instances show evident haste in preparation, but, as received, they convey a record of expenditure for fuel varying to the extreme mentioned above. A large number of plants are reported as burning from eight to ten pounds of coal per horse power per hour; very few, even with the modern equipment of higher expansion and condensing engines, were able to show a record below three pounds of coal per horse power, while other equipments of the same class report an equivalent duty with one-half of the expenditure of fuel.

As the inquiry circulars have only been in the hands of the different companies a few days, a large percentage of them have not yet reached the hands of the committee. It has been impossible in this short space of time to issue a complete report in time for this Convention. If the work can be continued until the next Convention the committee feel confident of being able to place in the hands of the members of this Association a report that will be of special value.

The tabulated statement of the reports received was submitted.

RATING THE CANDLE POWER OF INCANDESCENT LAMPS.[1]

BY DR. LOUIS BELL, CHAIRMAN.

YOUR Committee had not proceeded very far in the investigation of its subject before it discovered that the topic was growing, growing with a prodigious rapidity, so that we have been able to formulate, so to speak, only a partial report, a report that must necessarily leave untouched many things that we would have wished to touch, but which, we hope, embodies certain suggestions that may be of interest to those who have occasion to use incandescent lamps.

In the first place, the necessity for some rational rating of the candle power of incandescent lamps becomes evident in the experience of nearly every central station manager who has enterprise enough to keep watch of the lamps he is using. At the last Convention of this Association your president gave some admirable examples of the way in which the alleged 16 candle power lamps varied anywhere from 8 to 18 or thereabouts. Now evidently it is for the best interest both of the central station man and of the consumer that each should know exactly what is intended by 16 candle power glow lamps. It should not be left to the choice of the lamp manufacturer to make any sort of incandescent lamp he fancies and label it as of 16 candle power. There have been signs in this direction, as every station manager knows, although the manufacture of the incandescent lamp, it is only fair to say, has been very much improved of late. Now the questions that arose were about as follows: First. How shall we classify the power of incandescent lamps at all? Shall we classify it entirely by candle power, or if not by candle power to what standard shall we refer the light? or shall we classify it by watts consumed with specifications for efficiency or by watts consumed with specifications on candle power to put some limitations on the efficiency? After a considerable amount of deliberation, aided, we are glad to say, by consultations with a large number of gentlemen who are practical experts in incandescent lamp matters your committee came to the conclusion that the last mentioned method of classification was the simplest one to enforce, that is, incandescent lamps should be rated by the watts consumed, the actual power for which the consumer pays, but with a specification as to the candle power to limit the efficiency of the lamp to a practical value. By practical values I mean such as will not on the one hand produce an inordinate waste of energy, or, on the other hand, force the lamp far above its proper candle power and consequently rapidly burn it out. The interest of the lamp manufacturer evidently lies toward greater efficiency, because, by producing a very efficient lamp, such an one as will give large candle power with a small consumption of watts, he is enabled in the first place to give a fine, brilliant light that pleases customers, and in the second place to point with some pride to a real economy of power. Unfortunately, when this tendency is carried beyond a certain point, as every practical man knows, the life of the lamp is enormously shortened. A lamp that will burn from 1,000 to 1,500 hours at moderate efficiency, when forced to very high efficiency will burn a very much shorter time.

---

[1] Report presented by Committee of N. E. L. A., Providence, Feb. 18, 1891.

Now, having determined the proper way, in general, of rating incandescent lamps, there arose the important question of proper limitations to be set. We have been so long used to speaking of and dealing in 16 candle power lamps, that it seems inadvisable to abandon that standard. Given then the proposition that we ought to have a 16 candle power lamp, a candle power that has been sanctioned, as I say, by very long use, what do we mean by that 16 candle power? We might define our candle well enough, but do we mean that the lamp aforesaid shall give 16 candle power maximum, 16 candles mean horizontal, or 16 candles mean spherical illumination. Your committee is emphatically of the opinion that the mean horizontal candle power should be specified; in other words, that the normal 16 candle power lamp should give 16 candle power, taking the average of the horizontal illumination in all azimuths.

Next came the question of practical limits within which the candle power might be allowed to vary; of course, if we tied ourselves down to 16 candle power, meaning thereby horizontal intensity, we would be establishing a standard no lamp manufacturer could approach; in other words, it would be commercially impossible to make a large number of lamps at a low price and have the candle power of each one exactly the same. Certain limits must be allowed. Taking the limits as they are found in actual practice, we find them 5 candle power on either side of 16, sometimes even 7 or 8. These limits your committee considered far too wide, and therefore it entered into consultation with the lamp makers for the purpose of ascertaining how close to 16 candle power the limits could be set, and yet leave the manufacturer a simple and practical process. The result of this deliberation was to settle on about 1 candle power on either side of 16, that is, on the one hand, the largest variation which we could agree to admit in defining the normal lamp, and on the other hand, being a variation which came easily within the lines of commercial manufacture.

These two points determined, next came the unfortunate question of efficiency. As to the possible efficiency of incandescent lamps giving a reasonably long life there are as many opinions as there are lamp makers, besides a few stray opinions advanced by theorists, and still fewer advanced by practical electricians. A large amount of consultation was done on this topic. Some experts in lamp matters advocated the use of lamps giving the candle power on not less than 4 watts, others loudly proclaimed 3 or 2½ watts to be quite practical and a reasonable figure. In this regard we shall have to appeal to the central station manager. Your committee was necessarily at sea to a certain extent in determining on this particular point, but after a large amount of consultation both with the central station men, lamp manufacturers and experts, it considered for general central station use, taking into account the fact that sometimes they sell light by contract and sometimes by meter, a consumption of more than 4 watts per candle undesirable, particularly if the electricity is furnished by meter, for when the consumer is paying for more than 4 watts per candle power he becomes inclined to kick, and objects very seriously to the bills sent as not representing the proper quantity of light. Then, as to the superior limits of efficiency, on how small a number of watts is it possible to produce a candle power and at the same time have a lamp of reasonably long life and having a reasonably uniform efficiency throughout its life? The very best commercial practice seems to set the figure at a little over 3 watts. Without specifying, then, the efficiency of the normal standard lamp, your committee would suggest that a lamp giving over 15 and not over 17 mean horizontal candle power on a consumption of less than 60 and not less than 55 watts, represents the average conditions of central station practice better than any other type of lamp that could be readily found. I am quite aware that in setting this 55 watt limit your committee is running in the face of opinions which are entitled to some consideration, but it would call the attention of anyone who is opposed to that limit to the fact that with the normal standard lamp thus defined, if any lamp can be produced giving a candle power with good life on a little over 3 watts it still falls within the standard. The effect in that case would simply be this: That the manufacturer who could produce a lamp giving the candle power well and steadily on a little over 3 watts could furnish as the standard lamp a lamp that would come very near to the 17 candle power limit; in other words he would get the credit of having a little brighter lamp than some of his competitors and so would not in any way suffer by the establishment of the 55 watt standard. This suggestion for the normal standard incandescent lamp is the best that your committee is as yet able to bring forward, and we trust that it will fall reasonably near the limits that most of the members of the Association have found desirable in their actual practice.

Now, as to determining the mean horizontal candle power upon which our standard lamp is to be based. Several difficulties are encountered in this work. In the first place the distribution of light that is given by incandescent lamps is not altogether uniform; in lamps with twisted filaments, particularly if of round section, the distribution is very uniform, in lamps with straight filaments of round section fairly uniform; in lamps with straight filaments of square or nearly square sections, a figure something like exhibit "A" showing the maximum at very nearly 45 degrees from the plane of the filament; when filaments of rectangular section are employed having a considerable difference between the sides of the rectangle, the light varies in the most erratic fashion. Now for all lamps giving a uniform distribution of light a single reading on the photometer is enough to determine the mean horizontal candle power, and for, so far as I know, most of the twisted filament lamps, probably all of them, a single reading will determine the mean horizontal candle power closely enough for all practical purposes. When a lamp of this description (Ex. B) is reached, a single reading might, or might not, be fair to the lamp. If the reading was taken at the point of maximum luminosity it would be altogether too fair to the lamp, because a lamp that would give 16 candle power, 45 degrees off the plane of the filament, would give nothing like 16 candle power mean horizontal intensity. Contrariwise, measuring directly off the face of the filament would be very unfair to lamps of this general construction (and there is more than one make of them on the market) while a reading off the edge of the filament will give in nearly every case a very close approximation to the average. If one has a regular photometer at hand and can make careful measurements, three readings 120 degrees apart will give an approximation in nearly every case correct within one per cent.

Now, taking the worst case of distribution, the difficulties are even greater; a very irregular circle is the actual distribution. The outer circle as shown is the mean horizontal intensity and the inner circle is the alleged candle power of the lamp (that particular make of lamp is now no longer manufactured, so we are not treading on the toes of anybody present). In such a case no reasonable combination of readings would give the mean horizontal intensity. For all practical lamps, however, nearly all of those now in use, one reading will give a very close approximation, taken anywhere in the case of the twisted filament lamps, taken either with the filament edge on, or about 80 degrees off that point, in the case of our lamps having a squareish distribution. But in lamps of more irregular character, it is only fair to say that one reading is not enough.

There is one way, however, to determine the mean horizontal candle power, and that is by spinning the lamp above an axis as it is being tested; if a lamp be mounted in a rotating socket and spun rapidly about its own axis, the mean horizontal candle power can be obtained at once, if the velocity of rotation rises to about 300 or 400 turns per minute. This process has been tried several times with more or less success. It is tried in at least one lamp factory with uniform and unvaried success, and it is certainly worth an experiment in case we have to deal with very irregular lamps which throw their light erratically around a horizontal axis.

Appreciating the fact that the average central station man has not an elaborate photometer and usually has no man whom he can readily train to do accurate photometer work, your committee suggests the use of a lamp tester, its purpose being not to measure the exact candle power of the lamp, but to see whether it falls within the standard limits. For that purpose a very cheap and simple apparatus is something as follows:

Cut a board about 7 feet long—a little over 7 feet—and at about its middle point saw one-half way through the board and stick in a piece of tin painted black, about 8 inches square, or of any convenient size, with a 2-inch circular hole cut through it. Over that hole put the photometer disc—merely a piece of thin paper with a spot of oil on it. Just 36 inches from that photometer disc place a socket which can be twisted around its axis to carry the socket of the lamp that is to be tested. At the other end of the board cut a slot and on a little slide, made in the simplest way you can contrive, set a lamp socket for the standard lamp. Make the slot of such a length that when the slide that carries the lamp is pushed into its nearest point to the screen, the lamp shall be distant $34\frac{15}{16}$ inches. Make the slot of such a length that when the slide that carries the lamp is pushed into its nearest point to the screen, the lamp shall be distant $34\frac{15}{16}$ inches. Make the other end far enough over so that when the lamp is pushed to the extreme end it shall be distant $37\frac{3}{16}$ inches from the screen. The latter position will correspond to 15-candle power in the lamp to be tested, the former position to 17-candle power in the lamp to be tested.

As regards standard lamps. If you are fortunate enough to be near a laboratory, it is not a difficult matter to get 16 candle power lamps of the voltage you use, giving preferably 16 candle power right off of the plane of the filament, as that position is more easily determined when you are putting it in the photometer. I have written personally to Dr. Duncan, of Baltimore, asking whether from his testing bureau he could furnish standard lamps. I have not yet heard from him, but doubtless that testing bureau will be able to furnish lamps to give directly off the plane of the filament 16 candle power. These would serve as a standard. With this apparatus lamp testing can be carried on with great rapidity. The lamp to be tested and the standard lamp should both be on the same circuit in parallel, consequently exposed to the same voltage; the rheostat, in series with both, so that the voltage can be brought to the point intended. Measuring instruments of any kind you have at hand will give the consumption in volts and amperes. Then, placing the lamp to be tested in its socket and turning on the standard lamp, look at the photometer disc a little from one side, standing by the lamp to be tested so that you can shift it. If the lamp to be tested then is within the standard limits, under 17 candle power, when the standard lamp is pulled to the near end of the slot, the oil spot will appear bright, lighter than the surrounding paper. Pushing the standard lamp to the farther end of the slot, this spot should appear dark, if the lamp being tested is within the normal standard; thus in testing, two positive things are to be seen, one at each end of the slot; the photometer spot should appear bright at the near end of the slot and dark at the other; if not, the lamp is not standard. This convenient substitute for exact setting I think will eliminate an error that is very vexatious. It was felt by your committee that some such device was necessary in order to prevent careless photometer work on the part of linemen and station men to whom the work might be entrusted. It is very rarely that the manager of a station himself has the time, or cares to go to the trouble of going through this testing of lamps, nor is it always practicable for him to do so. It was the intention of the committee to provide a lamp tester that would determine the maximum and minimum limits without regard to exact setting, and the charts shown will be left with the Association for reference by any of the members who desire.

LIST OF ATTENDANTS AT THE PROVIDENCE CONVENTION.

New York.—Atkinson, E. P., Ackerman, P. C., Alexander, P. H., Baldwin, C. A., Barney, Gen. C. H., Bell, Dr. Louis, Burdick, J. P., Burton, Fred G., Bushnell, Nathan, Brown, M. W., Caldwell, Edward, Colvin, F. R., Candee, Capt. Willard L., Cook, E. L., Coles, L. S. Coles, Thos. L., Chalmers, David, Cheever, H. Durant, Castle, Wm. W., Corey, R. B., DeLand, Fred, Dillont, Col. J. Frank, Ditman, M., DeRonde, Frank S., Ellinger, J. O., Fineout, W. C., Fleming, W. H., Field, C. J., Faver, A. T., Gennert, E. F., Godfrey, J. W., Gordon, W. THIRTEENTH ANNUAL CONVENTION OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

TUESDAY, FEB. 17, MORNING'S PROCEEDINGS.

President Marsden J. Perry called the Convention to order at 11:15 A. M., in Freemasons' Hall, and introduced the Hon. Charles S. Smith, Mayor of Providence, who welcomed the Association to the city.

President Marsden J. Perry then delivered the following address :—

At this, our Thirteenth Convention, we have a double duty to perform—a duty to the past, a duty for the future. We who are absorbed with dealing with the problems of to-day, and in attempting to reach a little way into the future by anticipating the demands that may be made upon us, can well afford to pause a moment to pay a fitting tribute to those whose labors in the past have made our present possible.

We are here to pay to the pioneers of the electrical industries a tribute of intelligent appreciation of intelligence, and to recognize in a formal manner the magnificent realization of the inventor's hopes and the scientist's dreams, to erect a milestone that shall mark the closing of the first decade of the practical commercial application of electricity, a development which has shown grander results than ever before known in the industrial history of the world. I ask you to step back a few years, to the time when no electrical work, as we now know it, was in existence, and from that standpoint measure the meaning and value of what has since been done.

We are told that Franklin's kite experiment was made in 1752, and that in 1753 he invented the lightning rod. The age of electricity may be reckoned from that date.

In the year 85 A. F. (after Franklin), the first electrical company in the world was incorporated by a charter granted by the State of Rhode Island. This charter was granted in June, 1838, to E. J. Mallett and his associates, successors and assigns, by whose genius it was conceived, and what became of those aborigines of the electrical age, I cannot tell you. That Mr. Mallett and his associates, whoever they were—no other name is mentioned in the charter—were true prophets of science and industry, is unmistakably shown in their marvelous conception of the possibilities of their undertaking. The third section of their charter is as follows :—

"The said corporation shall have power to cause experiments to be made in electro magnetism, magnetism and galvanism, with a view of the development of said sciences, as a motive power for machinery or other useful purposes; also, to manufacture the necessary machinery and other apparatus therefor; to build and construct boats, vessels, railroad cars and engines to be moved by electro magnetism, magnetism of galvanism." Has any one to-day a broader view of the possibilities of electric power than this?

In selecting Providence for the meeting place of your Thirteenth Convention you builded better than you knew. You not only at this time celebrate the first decade of electric lighting, but you celebrate it in the birthplace of far-reaching appreciation of electric power.

In the year 91 A. F., Morse constructed the first practical telegraph line. He connected Washington with Baltimore by telegraph in 1844. Seven years before that he exhibited his telegraph in the University of New York. Between invention and success there was seven years of working and waiting.

In the year 113 A. F., Field laid the first successful ocean cable in 1866. Eight years before a cable was laid which operated but a few weeks. Before success, there were eight years of patient, courageous work, such as man has seldom had the power to endure.

In the year 122 A. F., Bell gave the telephone to society in 1875, and made all the people of the town neighbors. His years of faithful work preceding crowning success are well remembered.

In the year 125 A. F., Brush exhibited a light that caused people to think the sun had forgotten to set at the ordained hour. The first time the public ever saw a lamp burning in series was at the exhibition of the American Institute, held at New York, September 11th to November 23d, 1878.

Two isolated plants were then sold, consisting of a six-light Brush dynamo and six series lamps. One went to Messrs. Losier & Co., dry goods merchants, of Brooklyn, N. Y.; the other went to Messrs. Freeland, Loomis & Co., Continental Clothing House, in Boston, Mass.

The first arc light Central Station was installed by the California Electric Light Co., of San Francisco, in 1879.

In the year 127 A. F., Edison divided the electric current and produced miniature suns that might be placed wherever more light was desired for use or pleasure.

The first Edison isolated plant was installed in 1880, in the printing establishment of the Hinds & Ketchum Co., Brooklyn, N. Y. A paragraph in a circular issued by this company, under date of February 1st, 1881, is as follows :—

"Our building is 40x160, four floors, lighted on all sides and fitted throughout with Edison incandescent lights, operated by a special dynamo electric machine, operated on the premises. We are the first manufacturers in the world to put into practical operation this great triumph of American genius, which is a true substitute for daylight, showing all colors in their natural hues, and our friends are invited to call and see the operation of Professor Edison's wonderful subdivision of the electric current and vacuum lamp." Mr. Hinds writes :—"I think the proudest moment of my life was when I turned on the switch for the first time and saw the room lighted up by what seemed to be the greatest wonder of the world—the incandscent lamp."

The first steamship electric plant was one of Edison's, installed with 120 lamps, in the steamship "Columbia," of the Oregon Railroad and Navigation Co., Jan. 10th, 1881.

The first Edison central station was installed with 4,000 lamps, in Pearl street, New York city, September 4th, 1882. To start this plant Edison had to overcome more than electrical, mechanical and financial difficulties. He had New York Aldermen to deal with. The following occurs in an interview with Edison, published in the New York *Herald*, January 20th, 1881 :—

"When will you be ready to light New York?" Edison replies :—"I am ready now, but we have no permit. I find it hard to get the requisite Aldermanic condition. The company laid an application before the Board, the application was referred to the laws committee, and was reported back saddled with conditions which savor of a body of gas men rather than public servants. They wanted, in the first place, the company to pay ten cents per lineal foot for all wire laid down. That would be twenty cents for every foot of street, for we would run wires on both sides. That is over $1,000 a mile. This, too, when gas companies pay not a cent. The second clause was that we should light the streets at 10 per cent. above actual cost. The third clause was that after five years three per cent. of gross receipts shall go to the city."

This is an example of encouragement given by the first city in America to American genius, skill and enterprise.

Ten years ago the only electric currents in use were the feeble currents of the telegraph and telephone. There was then not a lineman nor a workman of any kind who had ever heard of the high tension currents we are using to-day for the services of light and power. No man had ever handled conductors carrying such currents, nor manufactured apparatus for operating them excepting in an experimental way. There was not an educational institution giving a course of technical training in electrical engineering. Consider this, then behold what has been accomplished in the first decade of electric lighting. A period of time no longer than Morse, Field and Bell were compelled to wait and work to span the chasm lying between invention and practical success.

Confine your observation exclusively to the United States, and you will find the electric light in use by six thousand isolated plants. Seven hundred steamboats of American register, 350 gas companies furnishing electric light and power, 200 street railroads operated by electric power, 1,500 electric lighting and power stations. Facts like these need no embellishment to make them eloquent.

Now look beyond the limits of this country and see the development of electrical industry throughout the world during this first decade. Never before has such a transformation taken place. And this is not the end—it is but the beginning of things that are to be.

American genius, skill and pluck has, in all departments of industry, secured within this century benefits of high value for all mankind. That this truth may be known for all time, it is our duty to preserve in the most enduring and instructive form proper records of the achievements of all American industrial pioneers. Soon a fitting opportunity will present itself for the celebration of the first one hundred years, by duly honoring the beginning of the second century of the American patent system. In that grand marshalling of those who made prophecies and who fulfilled them, who had the genius to see, and the skill, courage and patience to execute, we must see to it that electrical workers occupy their rightful place of honor. The interest begun here should reach full tide then and should culminate in placing in the National Museum at Washington a collection of drawings, models, relics, etc., illustrating the birth and development of electrical industries in America. Such a collection should give at a glance to the unskilled workman or the general public an intelligent idea of successive steps of progress and invention and construction that have led from the beginning of the telegraph and telephone to those systems of communication as at present perfected, from the first production of an electric spark to the light we now have; from the first lifting of a weight by an electric magnet to the present marvelous manifestations of electric power. It is of the highest importance that such a collection be made and preserved, not alone for the instruction of the people of our own time, but as a history for all, written in the forms of the things we use, thus enabling future investigators to determine the relative influence of the electrical industries in forming the character of our civilization, and in enhancing the degree of our prosperity.

One point is worthy of emphasis while engaged in this review, his is the year 138 after Franklin. Would society consent to be placed back to the conditions it was in when Franklin made his kite experiment, if it could thereby recover from the pioneers in electrical work all that they have personally retained from the wealth that has been created by developments from their initial undertakings? No, not for a single day. They have given to society benefits a thousand times more valuable than all they have have received or that it is possible to confer upon them. Their services are of that divine order in the measuring of which money values are impotent. Limits of time and space are unknown to them. They are with us, and others, but they take cognizance of no country, no race or generation. Their field is the universe. The benefits of their service are for all men. They receive tribute of grateful honor from all intelligence. Their work is of the past. Our work is from the future. What report shall be made at the celebration of the close of the second decade of electric lighting and power? The first Edison station has increased its capacity from 4,000 to 15,000 lamps in eight years. At this rate of increase, this plant will be supplying 60,000 lamps ten years hence. We cannot measure the limits of future developments. We have done much, but we have produced only a sample of what is to be. An observer states that there is not a plant in existence having a sufficient capacity to supply one-twentieth of the demand for light and power that now exists within practical working limits of its area of distribution. If this be true, then within ten years, if each station is to fully occupy its territory, and keep pace with the growth of population, its capacity must be increased many times.

The central station men of this country do not realize the possibilities of development that lie before them. They do not see many sources of income that are as yet untouched. The accelerated pace at which progress is now moving, will render the work of the next ten years enormously greater than all that was accomplished during 138 years after Franklin. The car of progress will not stop for us any more than it did for those who were before us. We have given it momentum, but we cannot hinder it. Let it be our ambition, then, as it is our duty, to supply every demand for every kind of light and power service within reach of our stations. Those of you who do not do this will induce competitors to come within your limits, to divide your business and erect an obstacle in the way of your growth that can be overcome only by buying out, or selling to, the intruder. To-day the whole territory is yours to hold, to occupy, to serve. Be the equal of your opportunity, and at the second decennial celebration of electric light and power, the capacity of your plant may be many times what it is to-day.

The records of the beginning of the electrical industries are being written for the imperishable pages of history. We have gained the strength of the difficulties that have been overcome, like the armies of volunteers that made ours a free nation. The forces now engaged in electrical war were recruited from every vocation. To-day over thirty educational institutions of high grade are preparing the best brains among young men to do scientific and technical work. The practical American workman who has proven by what he has done that his rank is second to none, the peer or skilled workmen of the world, is educating his helpers and associates in the practical school of daily occupation.

Enterprise is ever young; we are incidents; while an industry, like human energy and force, will go on forever; when we tire and seek our rest, younger men will be eager to fill our places. Let us, then, begin where we may. Let us honor ourselves by fulfilling our double duty, which is, to duly honor those who have placed us under obligation for the work they have done in the past, and so to do our work that our successors shall have equal cause for honoring us.

The President then declared the Convention to be opened for the transaction of business.

The Secretary then read invitations extended to the Association from the following:

The Providence Telephone Co.; The Union Club, of Providence, The Providence Board of Trade, The Corliss Steam Engine Co., the Rhode Island Tool Co., the Nicholson File Co., the American Electrical Works, and the American Institute of Electrical Engineers.

Mr. C. A. Brown, chairman of the committee on Copper Tariff, reported that the reduction of the duty on copper was embodied in the McKinley bill, which became a law, and that there was now a very low rate of duty—something like 20 per cent. of the former rate of duty on copper—in its various forms. This bill having become law and this being now the duty on copper, and no further action being required at the hands of his committee, he moved its discharge. Carried.

Mr. Brown then read a telegram from Mr. J. P. Barrett, Chairman of the Bureau of Electricity of the World's Columbian Exhibition, expressing his sincere regret that he was unable to be present at the meeting of the Association.

Mr. W. H. Markland then read a paper on ELECTRIC LIGHTING AS APPLIED TO STEAM RAILROADS.[1]

Mr. De Camp inquired as to the precise conclusions reached by the Pennsylvania Railroad Company, relative to the merits of electric lighting as compared with any other form of illumination on their cars.

Mr. Markland in reply stated that the battery system which had been tried some years ago had not proved a financial success and had been abandoned except on the Pullman Chicago Limited Express, and that was lighted by batteries in connection with a dynamo in the baggage car.

Mr. J. Burleigh drew attention to the fact that in his section the Pennsylvania Railroad Co. rented their lights from his company instead of running their own plant.

Mr. M. J. Francisco stated that he had been furnishing light to the Central Vermont Railroad Company for the last two years, lighting the railroad yard, the station and the round house. Mr. Markland's theory of the best plans was the same that he had adopted in Rutland, *i. e.*, placing lights upon the tops of poles, fifty feet above the ground, with lamps on top of them. In the old style of round house in use very serious trouble was met by the soot and oil accumulating on the lamp, reducing the insulation and permeating the working parts.

Mr. R. W. Pope drew attention to the fact that one strong recommendation for the electric light on board trains was its safety, and he drew attention to the accidents liable to occur with the use of gas and oil.

Mr. A. J. De Camp stated that his experience had been, that the time spent in trying to convince the public that electricity does cost money to make it, is wasted. But when corporations like the railroad companies, who are working for their own interests and are not trying to make money outside, put themselves on record that they cannot afford to use the electric lights, solely on the ground that it is expensive, he thought it would make more impression on the community as to the real cost of the article with which the members were dealing, than anything that might be said in the matter.

The President then extended to all members of the Association a hearty welcome to the Narragansett Electric Light Company's station, and announced that on account of the large number of important papers and reports to be presented, and also on account of the memorial session, the executive committee had decided to extend the meeting so as to include two sessions on Friday, making a four day's meeting. He also announced the formal opening of the Electrical Exhibition at 8 P. M.

The Convention then adjourned until 3 P. M.

TUESDAY AFTERNOON SESSION.

The President opened the meeting by reading the Report of the Committee on Underground Conduits and Conductors.[1]

The report was accepted and the Committee discharged.

Mr. E. R. Weeks then read the Report of the Committee on Relation between Manufacturing Companies and Central Stations.[2]

Mr. A. J. De Camp in referring to the report, said: "That is all right so far as it goes, but it seems to be a sort of stereotype action on the part of the Association, and as the Chairman has stated, it is an exceedingly difficult thing to get at, even when you have a case in point to base your actions upon. I have no suggestions to make as to a line of action to be taken either in a case stated or in any other case. But the same thing has gone on, right straight along, all the time, and the manufacturing companies, with a great deal of affability find a way of avoiding it. I have had occasion, within the last year, of seeing the operations of just those movements on the part of the parent companies. The case that I have in my mind is the case in which the Thomson-Houston people are the parties who are really the aggressors in the matter. They say, "Well, of course, the Thomson-Houston people have nothing at all to do with the Fort Wayne." We of course understand that the same people are interested in it. Now they have a territory where they observe strictly their agreements with the parties who have bought the rights to their apparatus, and do nothing. They sit passively by, but they are hissing on the other fellows with all their might and main. That case was stated—the case of Campbell, which I was talking about last year. The same thing has happened in Philadelphia in the last six months. Now there is one thing that has come to my knowledge of late which I am not prepared to say anything definite about, because I have not an answer to a letter I wrote on the subject, in the case of the parent Brush Company who originally sold their franchises to several companies in the East and West under a guarantee to protect them in their patents; that is they were only able to make those deals by stating that they had fundamental patents which would protect the company paying them their royalty, or whatever you may call it, in the use of the property. It has never been worth one farthing to the company that has paid for it. A notable case of the evil effects of that has been in New Orleans, where the original company that bought its right from the parent company in Cleveland has been absolutely wiped out, and they have been wiped out because of the competition that has come in there, encouraged by the very people that started them, and they have brought suit—all of which has been noticed by you gentlemen perhaps—in a very large amount, and as far as I understand, their contract with the parent company is precisely the same as the Philadelphia contract. You can just imagine how vigorously the Brush Company in Cleveland is going to prosecute those suits against that particular lamp because it is owned by the Thomson-Houston people. I do not imagine that they are going to push that thing very hard. I do not know what reply I will get from the attorneys in New Orleans to my letter, but my idea now is this: That if the claims of that company and others who are alike situated are not recognized by the Cleveland Company and they will not prosecute those suits in the spirit in which their contract was made, it will be a very good thing for the people who are now affected and who are likely to be affected to join in that suit with the New Orleans people and make a very vigorous fight on it. And, further, that if we cannot gain a point in that way, why, take it as they have put it. They have laid claim, I think, for $300,000 damages. Now, I think some movement of that kind by the members of the Association would have a very good effect, much better than going direct to these companies; I have never got any satisfaction out of that."

---

[1] See page 233.

[1] See page 239.

[2] See page 236.

The recommendation of the Committee was adopted and the report received and placed on file.

In the absence of the author, **Judge Armstrong** read the paper by F. H. **Prentiss**, on "Distribution of Steam from a Central Station."[1]

Dr. Bishop, in opening the discussion on Mr. Prentiss' paper, drew attention to the fact that distribution of steam on this plan had been successfully accomplished for more than twelve years, and that it was now employed in more than thirty different cities, besides the expensive plant in New York with which Mr. Prentiss was connected, which showed that it was a developed industry. He referred to the American District Steam Company, who constructed a short line of street mains in the Fall of 1889 for the Edison Electric Light Company in Kansas City. In the Fall of the same year the Ottumwa, Iowa, Railway, Electric and Steam Company, in addition to extensive street railway and electric lighting plants, had over two miles of street mains constructed to work in connection with their other interests. The exhaust from the engine connects directly to the street mains, which are also connected with the steam drums over the boilers. By means of reducing valves the pressure is under the control of the manager in charge, who can add live steam in any proportion required to the supply from the exhaust. They have two engines, one in connection with the street railway which runs from 6 A. M. to 11 P. M.; they run the electric light engine and dynamos during the hours required. They now have sixty-nine buildings taking steam at various points along the line, some quite large, such as the post-office, opera house, school buildings, churches, business blocks, residences, etc. The exhaust steam from the railroad engines supplies nearly all the steam required to maintain pressure in the two miles of mains to supply heat to the sixty-nine buildings. Part of the time a small amount of live steam is added. When the light engine is in use also, the present consumption does not use all of the exhaust. The pressure at the boiler house, in the street mains, is twelve to fifteen pounds. The pressure indicated one thousand feet therefrom is one to two pounds less; the pressure indicated 4,300 feet therefrom is three to six pounds less than at the boiler. These figures were taken when all buildings were taking their quota of steam, and still there was a large margin above what was required for the present consumption. At this date they had about fifteen per cent. of the probable future consumption. Another equal amount was in sight now for the coming year. Application had been made already for that increased consumption. The present earnings were, net, about thirteen per cent. upon the cost of this feature of their enterprise, with another equal amount in sight, as before stated, in the coming year which will involve no increase of expense excepting for fuel.

The apparent effect on the engines and boilers was nothing, except that twelve to fifteen pounds of extra pressure had to be carried. He also instanced the adoption of a similar steam distribution plant by the Springfield, Ill., Electric Company, and others, at Duluth, Minn., and Chester, Pa.

As to the value of the exhaust steam, he stated that each hundred horse power of boilers steaming at twenty to twenty-five pounds pressure has a capacity for heating 1,500,000 cubic feet of space, maximum. The minimum figure, allowing for all absorption of heat by engines, is 1,000,000 million cubic feet for each one hundred horse power.

Mr. A. L. Ide, of Springfield, Ill., stated that his company had made a contract with seven store buildings to heat them for five years with exhaust steam at a price averaging about $200 a year. The buildings contain about 100,000 cubic feet of space each. They did not contract for any more when they started last fall, because they wanted to be sure to have sufficient exhaust steam to supply them. They had now given about four months service which had been very satisfactory in every respect, warming the buildings satisfactorily in the coldest weather. They never have exceeded four pounds back pressure, ordinarily carrying two pounds only, and the gauge shows a reduction of about one pound at the extreme end of the mains. They estimated that the expense of furnishing this exhaust steam was trifling, and did not notice any difference in the consumption of coal required; they now found that with the surface exhaust steam they did not utilize over half. Next summer they expect to add about a thousand feet more of mains. He estimated that the receipts from steam are about one-half profit. It required no additional attendance, and it involved simply the interest on the investment on the plant and the slight additional fuel it requires.

In reply to a question of **Mr. J. A. Seely**, **Dr. Bishop** said that connection was made direct with the exhaust pipe, no drum being employed, simply a continuation of the street main. The exhaust pipe goes direct into the main. A very elaborate system of covering, of protection against condensation, was employed and a provision made for expansion and contraction of pipes. The system was known as the Holley system. The pipes could be laid at any depth in the ground; or run overhead, when necessary

Mr. Weeks said that his company had such a plant in operation now for about fifteen or sixteen months and had been very much pleased with its operation so far. They had cleared about fifty per cent. of the cost of the plant during the first year and he thought that they could considerably increase that net result by adding additional customers.

The Committee on National Insurance Rules had no report to make and was discharged.

The President recommended that a standing committee be appointed to formulate, and, from time to time, revise a code of instruction to be known and published as "Instructions of the National Electric Light Association for the Safe and Economical Wiring of Streets and Buildings for the Service of Electric Light and Power, and for the Proper Inspection and Maintenance of the Same."

This was adopted.

The Convention then adjourned until Wednesday, February 18th, 1891, at 10 A. M.

THIRD SESSION, WEDNESDAY, FEB. 18.—(MEMORIAL DAY.)

The Convention was called to order at 11:10 A. M., by the President, who drew attention to the triumphs achieved in electricity—and especially in the past decade, and which called for a fitting celebration at this time by the National Electric Light Association.

Letters of regret were read from Cyrus W. Field, Norvin Green, G. G. Ward, Alexander Graham Bell and Francis A. Walker.

The President then introduced one of the veterans of electrical service, **Mr. Thomas D. Lockwood**, of the American Bell Telephone Company, who responded for the Telegraph and the Telephone.

Mr. Lockwood remarked that while the telegraph of to-day was about fifty-five years old, nevertheless prior to that there had been numerous conceptions, but nothing practical—one of these appearing in a Latin book written by a Monk in the middle ages, and the conception, briefly stated, was that of two needles poised upon pivots and pointing to the periphery of a circle around which there were depicted the letters of the alphabet, and which would act as a dial telegraph when separated for a distance.

Mr. Lockwood then showed how the discovery, by Volta, of the galvanic pile, and that of Oersted, of the action of the current on the needle, made the telegraph of to-day a possibility.

He then passed to the early work of Morse and traced its development until success was obtained in the building of the line from Washington to Baltimore in 1844.

In this connection Mr. Lockwood drew attention to the regretable absence of Mr. James D. Reid, the veteran telegraph superintendent, who if present would have been able to relate many interesting stories of the pioneer days.

Mr. Lockwood then traced the history of the improvements upon the original Morse, and the work done on the duplex by Gintl and Stearns, the quadruplex by Edison, and on the synchronous multiplex by Delany.

Mr. Lockwood continued: "I am quite certain that I have not failed in holding out to my first view as to my ability to fill the shoes of Dr. Norvin Green. I do not feel that I have done justice to the telegraph. I am, however, a little more at home upon the next branch of my subject—the telephone. Sir David Brewster, one of the greatest scientific men of a scientific age, and who died about 24 years ago, was a Scotchman who for many years was at the head of scientific circles in England. More than once he was president of the British Association." Speaking on the telephone, Mr. Lockwood stated that some time between 1830 and 1840, Sir David Brewster had in his letters on "Natural Magic," closed a chapter devoted to automatic talking machines by saying "we have no doubt that before another century is completed a talking and a singing machine will be numbered among the conquests of science," thus showing the faith of the highest scientists in the ultimate accomplishment of what was now a complete scientific and commercial success.

Prof. Bell had realized this prophecy in the telephone which solved a double problem, namely, (1) How to make a metal plate copy the motions of all complex organs of speech ; and (2) How to make that one plate talk by electricity when that electricity was applied at a distance. He showed also how Prof. Bell was by training and education peculiarly fitted to solve this problem, which, as Sir Wm. Thomson puts it, realizes "the mathematical conception that if electricity is to convey all the delicacies of quality which distinguished articulate speech, the strength of its current must vary continuously, and as nearly as may be in simple proportion to the velocity of a particle of air engaged in constituting the sounds."

---

[1] See page 231.

Prior to 1876, said Mr. Lockwood, were not many industrial applications of electricity. Probably eighty per cent. of the persons interested in it were engaged in telegraphy, and the remaining twenty per cent. was divided between instructors of youth and persons engaged in electrotyping and electro-plating. He thought we should do all honor to the latter who, largely by rule of thumb, it is true, carried on some of the grandest uses of electricity from almost the invention of the voltaic pile in 1800 until the present time without knowing much about it, without any literature on the subject, with only five text books up to the present time which touch upon it at all, and yet who made that business a success. But all that was now changed. The civilized world glows with the illumination of electricity, the electro-motor is abroad doing our work, and the long suffering car horse and mule, are at last encouraged by the application of power to street railroads to believe that the day of spring has visited them ; while five hundred thousand telephones in the United States, and as many more in other countries attest the fact that people will, and must talk.

Mr. Lockwood emphasized the value of experiments which alone are the test of theory and speculation, and to which all the great improvements in the modern arts are due. (Applause.)

THE PRESIDENT then introduced Prof. Elihu Thomson, who responded for "Electric Lighting."

PROFESSOR THOMSON, in contemplating the work of the past few years, said that we must not fail to pay honor and tribute to Sir Humphrey Davy, the discoverer of the electric arc, and to Faraday, the discoverer of magneto-electric induction, the two phenomena which are now the bases of so many forms of apparatus. He described a visit to the Royal Institution and the difference he had noted between Davy's style of recording his experiments and Faraday's, and there was that contrast even to be seen in their work. Davy was, as it were, brilliant, jumping from one thing to another in great leaps ; while Faraday's was the painstaking work of the scientific investigator, who thought out carefully what he was about and when he had concluded his experiments wrote out just as carefully what he had obtained. The records of Faraday's were models of neatness, and precision in every way.

Prof. Thomson then traced the history of magneto and dynamo electric machines to the discovery of the invention of the Gramme dynamo, and the work of Wallace and Farmer, in this country.

Speaking of his own work in this field, Prof. Thomson remarked that he had taken up the investigation of dynamo machines about the year 1874, and had begun the construction of small models.

In 1876 he had built a small dynamo, which would run an arc light. It was his first attempt at a machine of that size, and, being successful, it led to the construction of other dynamos. When the construction of larger machines was undertaken there were difficulties to overcome, and not the least of those was the getting of steady power to run the machine. The first machine that was intended to be a commercial machine, and, in fact, the first machine which embodies the principle used in the Thomson-Houston arc apparatus—the three coil armature—was a machine capable of running four to eight lights in series. Prof. Thomson also spoke of the belief expressed by many who saw the machine, that it would require very little power to drive it, as the principle of the machine was then so little understood. This first machine was operated in a bakery, where the temperature reached 140°.

At last a company was organized which is now the Thomson-Houston Electric Company. It was organized in a modest way in the little town of New Britain, Connecticut, whither Prof. Thomson had removed. He had previously been teaching in the Central High School Philadelphia, and became electrician of this small company. Before it was organized an exhibit of apparatus was made at New Britain, in the "basket shop," as it was called, and Prof. Thomson related several amusing incidents of the troubles there experienced with the steam power. Soon another shop was obtained at New Britain and the making of apparatus for commercial use begun.

When the reverses due to the introduction of new apparatus had been overcome, the company was met by other reverses. The Brush Company saw their beginnings of success ; they were then the chief parties in the field of arc lighting. They bought up the majority interests in the little company in New Britain, apparently for the purpose of swallowing them and "laying them on the shelf." Subsequently, however, in the same year certain parties in Lynn, purchased the majority interest in the stock of what was then the American Electric Company, of New Britain, and started operations in Lynn, Mass. The Brush Company, remarked Prof. Thomson, had now been swallowed up by this infant that they tried to swallow. Such was fate. (Laughter.)

Prof. Thomson acknowledged his obligations to the members of the National Electric Light Association, in the great work which had been accomplished in so short a time, and referred to the ever-increasing business and the call for larger machines. They now had calls for dynamos up to 500 to 1,000 horse power, where, a few years ago, it was thought an unusual thing to hear a 150 or a 200 horse power machine spoken of ; and it looked very much as though in the near future machines of much larger capacity would be demanded for electric installations.

Referring to electric welding Prof. Thomson said that he did not know exactly when that art was discovered and that he believed that the formation of the National Electric Light Association was one of the steps in the process, figuratively speaking. (Applause). He referred briefly to his work in this department, which he had latterly, however, somewhat neglected for more pressing work in electric lighting.

With regard to the heating of our houses by electricity, Prof. Thomson thought it not at all likely that we will ever heat extensively by electricity, unless we can find some way of converting the energy of coal into electricity far more directly and less wastefully than is done in steam engines of the present day.

Referring to the previous day's discussion on the utilization of the waste steam from electric light plants for heating purposes, that seemed to be a direction in which much valuable work could be done.

In regard to the electric railway, Prof. Thomson hoped to live to see the time when some of our larger roads will be in operation as they should be, and can be, by electricity. He hoped also that the time might come when we shall have at our command an easy, direct method of obtaining electricity from fuel.

The President then introduced Mr. F. H. MONKS, General Manager of the West End Railway, of Boston, who spoke on "Electric Railways."

MR. MONKS briefly reviewed the early railway experiments of Davenport and Hall, and rapid strides that had been made during the last few years. Mr. Monks first saw the electric railway at Richmond, where he became thoroughly convinced when he saw what was being done there by Mr. Sprague and his fellow workers. He also related several curious experiences of the early days of electric railroading.

On the first day of January, 1889, after several months of preparation, the first electric car was started under the Sprague system, in Boston, and later the Thomson-Houston system was put in operation by the West End Company, in Cambridge. Since that time there had been no backward step and there had been continued and renewed expressions of opinion both by the officials of the company and by the public generally, of confidence in the system of propulsion of street cars by electricity. Mr. Monks expressed his doubts as to practicability of storage traction.

They had difficulties in Boston, of course, but they had also a glorious history to record in what had been accomplished. Last summer, during the visit of the Grand Army to Boston, they carried on their entire system, 3,000,000 passengers in one week, and of these more than one million were carried on the electric cars, without the slightest hitch of any kind, without any trip being missed and without any person being injured in any degree. (Applause.) At present they have sixty miles of electric track and are operating over three hundred cars. They are running about 18,000 car miles a day electrically or about three-quarters of the distance around the globe and carrying from 100,000 to 125,000 passengers daily by electricity. The experiment, if such it may be called at this late date, in Boston, had passed to a stage where the public not only consented to its extension, but actually demanded it. From all quarters of the very large area covered by the road with its two hundred and sixty miles of track, they had constant demands for the immediate introduction of the electric system ; so that where it had been a matter of grave difficulty heretofore to pacify the public mind respecting the matter of the introduction of electric roads, with them in Boston, it became now simply a question of not getting in too quickly.

Mr. Monks considered it advisable to go somewhat slow in the extension of electricity on his road, in view of the fact that electric railroading is still undergoing rapid changes in details of mechanism.

Mr. Monks, after careful consideration, was very strongly of the opinion that the future electric street railroads will not have their motors under the car. He did not believe it is possible for a motor to be built to be used under the car which would give that degree of life and durability which the rough usage of a street railroad is bound to impose on it. He thought, on the other hand, that the electric locomotive or motor car would be the solution of the problem. For many reasons the electric locomotive was decidedly preferable to the use of motors under a car. The first one, and perhaps, the most important was the fact that in Boston, Providence, Worcester, in fact, all the large New England cities, a double equipment of winter and summer cars was necessary. He doubted whether any street railroad could afford to buy electric motors with all the electric machinery incident thereto for two equipments, one for the box cars and one for the open cars. When electric railway engineers would come forward with practical scheme whereby the double motor equipment could be a avoided and something that could be depended on to work every day through 365 days in the year, they would be met with open arms

THE PRESIDENT then introduced Professor J. Elfreth Watkins, curator of the Smithsonian Institution in Washington, who read a paper on the "Place of Electrical Invention and Development in History." It was an able summary of facts familiar to electricians.

MR. R. W. POPE then offered the following resolution :—

Resolved, That the National Electric Light Association, assembled to celebrate the decennial anniversary of the establishment of the electric lighting industry in the United States, fully appreciating the value of the discoveries and inventions of Joseph Henry, heartily approves of the proposition now before Congress to bestow substantial recompense upon the daughter of the great discoverer who, during a life time devoted to science, received no financial compensation for the benefit he conferred upon mankind.

Resolved, That a copy of these resolutions be forwarded to both Houses of Congress.

The resolutions were unanimously adopted by a standing vote.

MR. E. R. WEEKS drew attention to the fact that in Kansas City where the oldest Thomson-Houston central station is located, they were still operating some of the original ten-light machines built by the original American Electric Company in the old factory in New Britain, mentioned by Professor Thomson.

THE PRESIDENT then introduced Mr. J. H. Herrick, first vice-president of the Edison General Electric Company, who, in the absence of Mr. Edison, spoke on "Incandescent Lighting."

MR. HERRICK expressed his inability to fitly represent Mr. Edison, and briefly reviewed the history of incandescent lighting, and showed how the substitution of the high resistance filament for the low resistance, previously worked upon by many, had made incandescent lighting possible. Mr. Herrick emphasized the fact that no man was fit to belong to the electrical fraternity who did not believe in the scientist's dreams. (Applause.) What we had achieved in the past was largely owing to the dream put into reality, of our scientists. What we may expect in the future will depend upon by how much faith, by how much energy, by how much genius, we endeavor to realize the dreams of the scientists.

MR. E. W. RICE, JR., supplemented the remarks of Prof. Thomson, by some interesting reminiscences of Prof. Thomson's early work. He related how, when he visited the Central High School, at Philadelphia, one afternoon after school to examine some of Prof. Thomson's old works, he saw there a dynamo which the Professor assured him was the first one that he had ever built. This dynamo, curious to relate, was so wound and connected by Prof. Thomson on different occasions that it involved many of the principles which have since become well known, but which at that time were unknown. He had the winding so arranged that the machine could be used in shunt, in series, and in series-shunt, which was practically known to-day as the compound winding, and which was now used so extensively. Prof. Thomson did not publish it at that time, for the reason that he did not consider it to be a particularly important piece of work. Prof. Thomson had done a great many things of this kind that were equally great but which seemed to him so ordinary, and such matters of course, that he neglected to say or do anything about it.

Mr. Rice related his early experience in the service of the Thomson-Houston Company from its inception, and the easy times then had, as compared with the ceaseless work now demanded by the business.

MR. GEORGE M. PHELPS then presented the following resolution

Whereas, The members of the National Electric Light Association assembled in its Thirteenth Convention have learned of the serious illness of Mr. George Worthington whose genial presence is missed by all, and whose conspicuous services to electrical industries in promoting the organization of the Association is recalled by all, it is

Resolved, That the Association hereby express its cordial esteem for Mr. Worthington, its appreciation of his many services and its heartfelt wishes for his early recovery of health and strength, and that the Secretary be requested to forward a copy of the resolution to Mr. Worthington.

The resolution was carried unanimously.

THE PRESIDENT then introduced Mr. FRANK J. SPRAGUE, who responded for "The Utilization of Electric Energy for Power Purposes."

As personal reminiscences were in order, Mr. SPRAGUE recalled to mind the fact that in 1879 he was on duty on board of a naval vessel of the United States on the coast of Japan. He had before that time been at the Naval Academy, graduating there in 1878, and just at that time Edison, Bell, and other electricians were prominent in the field, and there grew up in his mind a love for electrical matters and the desire to be associated some way with electrical developments. The United States Navy department at that time was not very encouraging to any such ambition. He went the way of all other midshipmen and drifted out to Asia, but the stories came of the discoveries being made in electric lighting by Thomson and Brush, and he became very nervous. Even at that time he was trying to invent an electric motor, and finally obtained permission to return to the United States in a sailing vessel. Arrived here, he went to Ansonia, Conn., and saw an experiment in the transmision of power which greatly impressed him. Mr. Sprague pointed out that Mr. Wallace, of Wallace & Sons, of Ansonia, was a man whose position in the history of this enterprise had never been fully appreciated. Mr. Wallace had one of the old four-pole armature machines, connected with a dynamo. He turned on the current and soon the machine was running two or three thousand revolutions a minute, and then deplored the fact that it was of little or no value as it slowed down and stopped when a brake was applied. He had overlooked the most important fact that he had to deal with, viz., that the energy developed was made up of two factors, namely, the torsional effort and the speed at which the armature revolved. Later on Mr. Sprague experimented with a Wallace-Farmer machine at the Brooklyn Navy Yard, but his duties soon called him out of the United States, and it was not until 1882, at the Electrical Exposition at London, that he was brought to a consideration of the tremendous advance that electricity was making.

Speaking of his early electrical railway work, Mr. Sprague said that few were familiar, perhaps, with the inside difficulties with which he had to deal. The contract for the road in Richmond was taken in 1887. He had never seen the road, and remembered to this day, the impression that came over him. He had been talking with John Stephenson, the pioneer car builder of the United States, and who said, "I do not believe that any self-propelling car can operate under street car conditions. I am acquainted with fourteen of them in the city of Paris." Mr. Sprague's answer to this was that there had been one difficulty with those, namely, that not one of them utilized the weight of the car for the purpose of traction. The first tractors that were built by Mr. Sprague were built for storage battery experiments on the West End railway, in Boston. Subsequently when he went to Richmond he saw a grade of 10 per cent. This, everyone predicted, could not be successfully mounted by an electric car, but after almost insuperable difficulties, and not a few amusing incidents, complete success was finally achieved, and the practicability of electric railroading, on a commercial scale, completely demonstrated. Mr. Sprague here paid a glowing tribute to the industries of the city of Providence, and referred to the fact that the success finally attained in Richmond was largely due to materials and work furnished by Messrs. Brown & Sharpe, the Armington & Sims Engine Co., the American Electrical Works, and the Bridgeport Brass Co., of Bridgeport, Conn.

As to the future of the electric railway, Mr. Sprague had heard with some interest what Mr. Monks had stated. The latter's objections to the double equipment had been based somewhat upon the cost. Mr. Sprague referred to the changes that the electric lighting apparatus had passed through, and none could doubt from the changes that electric railway apparatus had gone through, that it was going to be made more simple, lighter, stronger, more reliable and at much less expense; so that the objection which Mr. Monks raised was not an entirely sound one. It was based upon past results not upon future promises. The gearing of the present motor, Mr. Sprague said, would disappear from the electric motor of the future, and it was a very near future. It would also be an electric motor driving direct without any reduction whatever. Its revolutions would be coincident with the revolutions of the wheel. The day of the gearing was fast disappearing, and those who had had experience with gears on electric motors could surely feel encouraged by that fact.

Of late Mr. Sprague had been in exactly the position of Prof. Thomson, in which the infant swallowed up the larger specimen, and he had always been very much in the position in which the infant got very thoroughly swallowed up. Regarding the electric railway problem in New York city, the question of rapid transit is coming to the front. That New York would eventually have electric railway transit no man who knew the future of this industry could doubt. Exactly what form it would take no man could tell. While he was an advocate of one wire, if necessary, overhead, Mr. Sprague said he was an advocate of everything being put underground as far as possible. He did not believe in the theory of God's free air in New York city, where the air is monopolized by three things—buildings from 10 to 14 stories high, the elevated railroads, and the Bell Telephone Company. But he believed in God's free earth, where one could go independent of grades and independent of weather conditions. There was a most remarkable example of the perfection of that method of operation in London, and his prediction of its complete success, based on a visit some time before the starting of the City and South London railway, had been fully justified by the results now obtained.

MR. F. S. TERRY, of Chicago, then gave some reminiscences of the organization of the Association at Chicago in 1885.

The meeting then adjourned.

AFTERNOON SESSION, WEDNESDAY, FEB. 18.

Invitations to inspect plant and buildings were received from the Providence Steam Engine Co. and the Young Men's Christian Association.

THE PRESIDENT: The first item on our programme this afternoon is a paper by Prof. Elihu Thomson on the Electrical Arc and its Use in Lighting.[1]

---

[1] See page 225.

Prof. Thomson then read his paper. He was followed by Dr Louis Bell, who reported from the Committee on the Proper Rating of Incandescent Lamps.

The President: Are there any remarks on this subject? As there does not seem to be any, the next business will be a report from the Committee on Legislation, and Judge Armstrong will make the report.[1]

REPORT OF COMMITTEE ON LEGISLATION.

Judge Armstrong: In making the report of this committee, I will state that it was the idea at the outset to have a representative on the committee from each State in the Union, to receive, at the headquarters of the Convention, the secretary's office, a report of all matters of legislation, pending in the various State legislatures. Very few, if any, of these reports, have been received. So that I presume it is safe to apprehend that very little legislation outside of the ordinary course has been, or is being, attempted. The most of the State legislatures being now in session, of course the report cannot be and is not as full as we would be able to have it at a summer convention. In our own State, New Jersey, the regular line of bills to bury all wires underground, to put them 100 feet above the ground, and to carry them along in various ways, are always there. (Laughter.) They have a peculiar name, not entirely complimentary or polite to the legislatures to call it, and so in my report I will say nothing about what we usually know them as. (Laughter.)

In making this report I presume we all, as representatives of companies, must remember that we have more than a commercial duty to perform. No electric light company, supplying light, can claim to be entirely or solely an independent business corporation. Every one of us has assumed for his company certain public duties and responsibilities. When my company engages to light a city it has engaged in a very serious responsibility. We, therefore, are more or less reasonably subject to legislation and legislative enactments, from municipalities, as well as from States and State legislatures. Being so, there is grave danger, however, that that same license, same power, properly given, may be carried to dangerous and injurious accessions from mistaken zeal, or other reasons.

I have a report here from Mr. George C. Maynard, from the District of Columbia, in which he says:

REPORT OF THE NATIONAL COMMITTEE ON LEGISLATION. SECTION FOR THE DISTRICT OF COLUMBIA. BY GEORGE C. MAYNARD, MEMBER OF COMMITTEE.

It has been my special duty to look after Senate bill, No. 4329, introduced by Senator Hale on the 15th of August, 1890, and referred to the committee on census.

A copy of memorials adopted at the Twelfth Convention, was mailed to all members of the Association and to boards of trade and commercial bodies, from the office of the secretary, in New York. In addition to these, 500 copies were mailed from Washington to various other persons and corporations.

Resolutions, strongly urging the passage of the bill, adopted by the following named organizations, have been presented to the Senate and referred to the census committee: National Board of Trade and Transportation, N. Y. City.; Indianapolis Board of Trade, Indianapolis, Ind.; Master Builders' Exchange, Philadelphia, Pa.; Chamber of Commerce, New Haven, Conn.; Merchants' Exchange, St. Louis, Mo.; Retail Grocers' Association, Lincoln, Neb.; Commercial Club, Kansas City, Mo.; Association of Edison Illuminating Companies; Norwich Board of Trade, Omaha, Neb.; Wilkes Barre Board of Trade, Wilkes Barre, Pa.

In response to the memorials sent from Washington, I received from a considerable number of prominent companies and individuals communications stating that special personal appeals had been made to Senators and Representatives, asking their support of the bill.

Accompanying these replies were copies of letters from many Senators promising their cordial support of the measure whenever it should come up.

These communications were from: The Standard Underground Cable Co., Pittsburgh, Pa.; The Utica Electric Co., Utica, N. Y.; Citizens' Illuminating Co., Brooklyn, N. Y.; Wheeling Electrical Co., Wheeling, W, Va.; The Simplex Electrical Co., Boston, Mass.; J. J. Burleigh, Camden, N. J.; Wm. B. Wilson, Philadelphia, Pa.; F. B. Knight, Austin, Texas; Geo. N. Stone, Cincinnati, Ohio; M. B. Leonard, Richmond, Va.; H. B. Chamberlain, Denver, Col.; George M. Dugan, Jackson, Tenn.; Noah H. Cheever, Ann Arbor, Mich.

In addition to this work, which is of record, a great deal has been done by members of the Association and others, by private letters to, or personal interviews with, Senators or Representatives. So far as learned, not a single Congressman has made any objection to it and nothing but the extraordinary pressure of important business has prevented its passage. It may reasonably be expected that the bill will pass at this or the next Congress.

The Illinois Electric Lighting Association has sent out to its various companies a circular referring to matters of legislation in the State Legislature of that State, which is now engaging their attention as follows:

Illinois Electric Lighting Association.
53 Dearborn street, Chicago, Jan. 17, 1891.

Gentlemen: An effort will be made at the present session of the State Legislature to pass a bill authorizing cities and towns in Illinois to operate electric lighting and power plants for the purpose of commercial, as well as municipal lighting.

The injury to our mutual interests which would result from any such legislation is too apparent to call for special comment. One and all of us who have investments in electrical central stations are deeply concerned in the defeat of any measure which so palpably aims at our very existence. The urgency of the situation demands immediate and united action on the part of all concerned in electrical distribution. The passage of such a bill means the practical destruction of our capital, and if any efforts on our part can avail to thwart this movement, now is the time to put them forth for the sake of preservation.

If each one of us will use the influence he may be possessed of with the local representative to the Legislature, and if each company will lay the facts before the Board of Directors and induce them to bring the weight of their arguments to bear upon our Legislators, it is possible that the designs of the demagogues may be frustrated.

The Illinois Electric Lighting Association was organized with a view to just such an emergency as this. The responses to the calls which were sent out at its inception were very few in number, probably because at that time the central stations throughout the state did not appreciate how soon they might be called upon to act in concert. Small as the Association is, however, it proposes to do all that it can, but it is evident that its work would be much more effective if it were more representative of all the central stations in the state, and it is suggested for your consideration that you take the matter of joining the Association once more under advisement. In the meanwhile it is imperative that the personal efforts of everybody interested be exerted toward the defeat of the proposed action of the Legislature.

The acknowledgment of this letter and a statement of just what you can and will do to this end will be appreciated and will probably greatly aid in accomplishing the work we have before us.

Yours truly,
C. H. Wilmerding, President.

May I urge upon the representative of the companies here, particularly those who may be upon this committee, that they will take pains to send any information concerning the matters of legislation. In the report of our proceedings the secretary has compiled here all matters that he may get hold of relating to legislation before our various State Legislatures and what was done with various projects. There were some mighty novel projects introduced, and this will show what has been done. There are some interesting matters which have been, and are being, considered by the New York State Legislature, and also by the legislature at the present time in the State of Massachusetts. There will be found some very interesting reading in this book for those who are concerned, as we all are, in these matters, and who may all be concerned in these various items of legislation.

I suppose that Massachusetts has had the most uncomfortable experience lately of any of the states. Mr. Everett W. Burdett, who is the attorney of the Massachusetts Electrical Association, of Boston, is here to-day, and he will make a report upon matters in the Massachusetts Legislature. Mr. M. J. Francisco, from Rutland, will, I believe, make a report of what has been done in Vermont. Now, if we can get to the secretary all of the bills and measures that are pending before the various State Legislatures, and a statement of what has been done concerning each of these things, it will make in time a very valuable library upon this one point.

Mr. Edward W. Burdett, of Boston: I may premise the short report which I shall read with a statement, which I dare say will be disputed by nobody, and that is that in Massachusetts we have now, and have had in the past, more attempted legislation to the square inch than any other community, large or small, within the boundaries of the United States. Our experience has not been as yet painful, because nothing has been accomplished of any account upon the other side, but it has certainly been interesting, and I think it will be instructive to those representing this interest in other states. Referring for a moment to what has been said by the chairman of your committee—and I appear here in the place of Mr. Gilbert, who is a member from Massachusetts, and at his request—I may say that last year, and this, we have had printed a copy of every order or suggested law which is pending, or has been pending, before our Legislature, and that has been sent to about five hundred persons in the State directly interested in the industry, and in that way we have spread throughout the length and breadth of Massachusetts accurate information as to what was on foot, and followed it up, as I did yesterday, for the year 1891, with brief statements of reasons which should be given adverse to the proposed legislation. I think the list of subjects which were before the Legislature of 1890 are printed in the volume of the Association's last Convention, although I have not had an opportunity to examine it, and the same matter has been printed for the year 1891, within a day or two, and is to be distributed forthwith.

---

[1] See page 246.

The matters affecting electric lighting interests which were before the Massachusetts Legislature of 1890, are reported in the proceedings of the last Convention of this Association. They consisted of sixteen orders and numerous petitions, upon all of which action was had by committees of the Legislature. The only law which resulted from this agitation, was Chapter 404 of the Acts of 1890, relating to the regulation and supervision of wires over streets or buildings in cities. This act requires the suitable insulation of all wires at points of attachment, strong and suitable supports, the removal of all abandoned wires, appliances calculated to prevent currents of electicity capable of injuring electrical instruments or causing fire from entering buildings, and the tagging or marking of each wire or cable so as to designate the owner or user thereof. It further provides for the appointment of an officer to supervise all wires in cities, to remove abandoned wires, and generally to have the supervision of the use of wires.

There is pending before the present legislature a proposition to extend this act to the towns as well as the cities of the commonwealth, and to enlarge its provisions in its application to the city of Boston.

The agitation in favor of the enactment of a law to permit municipalities to own and operate gas and electric light plants resulted in a bill which was passed to be engrossed by the House, but it was referred by the Senate to the Legislature of 1891. This bill is now pending before the present joint committee on manufactures. While this bill was pending in 1890 the House of Representatives required the opinion of the justices of the Supreme Judicial Court upon the questions whether it was within the constitutional power of the Legislature to enact a law conferring upon cities and towns the power to manufacture electric light for use in the public streets and buildings of such cities and towns, and for the purpose of selling the same to their citizens. Both questions were anwered in the affirmative. The decision mainly turned upon the question whether the manufacture and distribution of gas and electricity by cities and towns for illuminating purposes is a public service within the meaning of the Constitution (part II, chap. 1, sec. 4). The Court held that the maintenance of public streets and buildings is a public service; that they may be lighted at the public's expense; that the means of lighting are a matter of expedience; and that the legislature may authorize this to be done by any appropriate means which it may think expedient. As a question of constitutional power, the right to authorize cities and towns to buy gas and electricity for their use, cannot in the opinion of the Court be distinguished from the right to authorize the manufacture of it for their use. The first question was therefore answered in the affirmative.

The second question was one of more difficulty, owing to the difficulty of defining with entire accuracy all the characteristics which distinguish a public service and a public use from service and uses which are private. But the same conclusion was reached. The Court did not consider whether the furnishing of gas and electricity for supplying heat and power can be regarded as a public service, and expressly they did not pass upon that question.

This opinion of the justices having been received, the bill was taken up by the House and passed, though in a somewhat different form from that submitted to the Court. It permits any of the cities or towns of Massachusetts, not only to establish plants by purchase or otherwise, for municipal purposes, but to supply light, heat and power by means of gas or electricity to any of their inhabitants. It also permits any city or town thus establishing a plant to supply gas or electricity, for any or all of the purposes named, to adjoining cities and towns and to the inhabitants there. It contains no provision requiring the purchase by cities or towns establishing municipal plants, of plants already existing in such places, and permits the purchase of only that portion of existing plants that consist of "real estate or is attached to real estate so that it cannot be removed and rendered available elsewhere without material loss, injury or expense." In case of companies supplying both gas and electricity, the bill permits the purchase of one or the other branch of the business as the town or cities may elect. Notwithstanding the failure of this bill to become a law, the town of Peabody voted to establish a town plant for lighting its public street and incidentally to utilize its surplus power and apparatus in supplying private consumers. A bill in equity was brought to restrain the town from carrying this vote into effect. The case has been decided by the full bench of the Supreme Judicial Court, and will be recorded under the name of Spaulding vs. Peabody in vol. 151 Mass. Reports.

In deciding this case, the Court said "that the authority claimed for the town is not within any of the customary powers which towns from very early times have exercised, and must be derived, if it exists, from the statutes relating to towns." The authority was claimed under the provisions of a statute which employs language first used in an act of 1892—that a town may grant "money for all other necessary charges, arising in such town," and from the authority of towns to erect and maintain street lamps. But the Court pointed out that the phrase "all other necessary charges," has always been given a very limited scope, and that special enabling provisions have been deemed necessary whenever extensions of the courtesies of town expenditures have been sought. As to the claim that the power was incident to that of erecting and maintaining street lamps, the Court said: "The subject of construction and maintaining gas or electric works for the manufacture of gas or electricity, and the distribution of them through the streets of towns and cities, for the purpose of furnishing light, is one of too much importance to be attached as a mere incident to the power given to erect and maintain street lamps, and we think that if the legislature had intended that towns generally should have authority to erect and maintain such works, the authority would have been plainly expressed in statutes, with such limitations and accompanied by such restrictions as the legislature might think it prudent to establish. We see no indication in the existing statutes that the legislature intended to make provision for the exercise of such authority by the towns of the commonwealth." In order to leave no doubt upon the question whether towns and cities can, under existing laws, establish and maintain plants for municipal purposes only, some of the opinions concluded as follows: "If we assume that the only action now contemplated by the town of Peabody is the erection and maintenance of electrical works for the purpose of lighting its streets, still we are of opinion that the vote is beyond the legal rights and power of the town. P. S. Ch. 28 Sec. 129."

This decision upon the existing state of the law in Massachusetts as well as the opinion of the justices upon the constitutional questions involved, are herein stated with some particularity-owing to the importance of the questions and the eminent authority of the Court which has passed upon them. While both opinions rest largely upon the particular language employed, in the one case in our Constitution, and in the other case, in our laws governing towns, they involve the consideration of such important general principles that they are worthy of study in any jurisdiction.

In connection with the bill for municipal ownership, the committee on manufacture has before it the recommendation of the Governor, that the powers of municipal corporations be enlarged by general laws in the matter of "municipal control of municipal work and ownership of the instrumentalities for its performance,"—which it will be observed does not go to the extent of recommending the enlargement of the powers of towns and cities so as to enable them to manufacture and supply gas or electricity for commercial purposes. The Governor is on record against an extension of the law in the latter directions. In addition to the bill above referred to and the recommendation of the Governor, there are orders covering the same subject matter and numerous petitions in aid thereof; including a petition to the common council of the city of Boston. The extent to which some of the petitions go, is shown by the fact that in one case the passage of a law is prayed for, to enable cities and towns to engage in all lawful business that the citizens of such cities and towns may desire to enter into. Another one prays for a state loan of $3,000,000 to cities and towns, to enable them to build for the people, similar to state loans to railroad corporations. Separate petitions have been filed by the towns of Danvers, Peabody and Hudson, and the towns of Brookline and Melrose have voted to appear in favor of the general legislation.

Mr. Burdett then enumerated a number of measures now in committee, proposing to touch electrical interests in various ways. He then said:

"The foregoing statement includes, in outline, all matter of legislation and adjudication, with one exception, touching electric lighting interests which have arisen in Massachusetts since the last report. The exception referred to is the decision of the Supreme Court in the case of Suburban Light and Power Company vs. The Aldermen of the City of Boston, reported in Vol. 150 Mass., Reps. In this case it is decided that the granting of pole locations to electric light companies is not mandatory under our statutes (P. S. Ch. 109 Sections 2 and 3) upon aldermen or selectmen, but rests entirely within the discretion of those officials."

MR. FRANCISCO:—Speaking for the State of Vermont, I would say that we have not had very much trouble. The only case we have in my own town, Rutland, was about a year ago, in regard to municipal ownership. The aldermen conceived the idea that they could furnish electric lights without any expense to the citizens. They became convinced that that could be carried out through the influence of outside parties, and the wonderful stories told by different people; but by concerted action we had the matter referred to the popular vote, letting the masses vote upon the subject, as they did in the regular election, and the result was that the vote cast was 10 to 1 in opposition to municipal ownership, which eventually ended all strife on that question in that town for all time to come, I think. In the Legislature we had a bill introduced allowing one company to occupy the poles of another company, and that bill was killed in the committee room. We also had a bill introduced, which became a law, compelling all companies to remove all crooked poles, or poles that were not first-class in every respect, and replace them with new straight and perfect poles, and paint all poles within the city limit. We had a bill introduced at the last session requiring all electric light companies in running their lines to run the lines entirely distinct and in such a manner as not to interfere with the business or the wires or occupation of the telephone companies. That bill died a natural death in the committee room. There was also a bill introduced at the same time requiring telephone companies to comply with the same law and not run anything but metallic circuits with proper insulation. When that came up the telephone companies where anxious to have it die, and that died also in committee room.

Mr. George R. Stetzel, of New Bedford.—I should like to inquire if there has ever been a case where an electric light company had asserted any right to any property in the street in the use and transaction of their business? I represent a company in the State of Massachusetts, and, as I understand it, and as we act, we are very much in the position of the popular interpretation of the Dred-Scott decision. We have no rights that the white man is bound to respect; the city does as it sees fit in every instance, and we don't know of any method of redress. Out of perhaps eight hundred poles there are from eighty to one hundred that are used for any purpose that the municipality may see fit to put them to. Within the past three months the city has been establishing a police signal system; they have put their boxes on our poles, sawing some of the poles two inches needlessly, and it looks to me maliciously, that they may have a base for the box to rest on the pole. They have not only done that, but they have taken the wires from the top of the poles down through the boxes through an iron gas pipe, and from that box they go directly into the ground. My linemen say it will be a difficult thing to sit on the top of that pole in damp weather when, if any trouble should arise, I might order them to go to the top of the pole to rectify it. While I have filed a protest with the City Government and a notice that I shall hold them responsible for any damage to my workmen or to citizens, there has been no action taken as regards remedying their gross imposition on our rights, if we have got any. It seems to me that we should not only act a little on the defensive, but that in this matter if we have any rights we should assert them. I do not know that we have any rights, but it certainly is very disagreeable to a manager to have the best property which he has, confiscated in this way without any knowledge or consent of it on his part. The first I knew of the establishment of this police signal business by the city was that they were established and they were there.

Mr. Burdett:—And I wish to correct some of the ideas which Mr. Stetzel erroneously holds. If he has been advised that he has no right to the exclusive use of his poles, he has been incorrectly advised. There is a very great doubt as to the right of the city to interfere with a pole which has once been set, except to change its location. Now, as to the aggressive attitude which he speaks about, I would say that the difficulty with the gentleman is that he has not attended to these things at the State House in Boston. I never saw his face until this afternoon.

Mr. Stetzel:—I am new in the business.

Mr. Burdett:—Your company, according to my recollection, is not a member of our organization, who are fighting these things. If it had been you would have been kept informed of what was going on. However, sir, I shall be very glad to see you in Boston at our meeting to-morrow when we shall attempt to inaugurate something in the way of aggressive action. As a matter of fact, the electric light association, which I have had the honor to represent, have been fighting for their lives, and not fighting for the other fellows, and that has got to go on until we have strangled this insane agitation, and then we can turn upon them with something in the nature of an aggressive warfare. The position before the committee to-morrow is to take away the rights which I say now exists. It arises out of the petition of the mayor of Salem to be permitted to have all boards of aldermen and selectmen given authority to revoke absolutely every pole location in a city or town without any reference to prior grants which have been acquired. There is only one way of fighting it, and that is for all the companies to come together. The telephone companies and the street railway companies have joined us, and have all combined, and we propose to stand up for the rights which we now have. I say this to the gentleman, that he has rights with his poles in the street, and he should join us and help to maintain them; and I shall be glad to see him in Boston. A gentleman sits here at my right who represents a company from the eastern part of the State, who can testify that his particular company was saved from competition with a company which would have run him out of the town in spite of all he could do in protection of his rights, because they proposed to use a water power which up to that time had not been used. (Applause.)

Mr. De Camp. (In the chair.)—I would say that in the State of Pennsylvania the municipal authorities recognize the rights of the companies to their poles when they have once become established. I don't know that a company has ever been interfered with. The city of Philadelphia makes a respectful application to us for the right to use our poles as we do to them for the right to use theirs. Some five years ago when the question of removal of poles was up before the Legislature the very eminent counsel who argued the case there took the position, which did not seem to be questioned, that in case such a law was passed, which would mean the destruction of a vast amount of property for the use of which it was erected, the companies would be entitled to compensation. That, of course, has never come to an issue, but there seemed to be no two opinions about it.

On motion, the Convention then adjourned until Thursday, February 19th, at 10 a.m.

FIFTH SESSION, THURSDAY MORNING, FEBRUARY 19.

The session was opened by the reading of a paper on "The Ferranti System," by **Mr. C. D. Haskins**.[1]

In reply to a question by **Mr. M. D. Law**, as to the method employed by Mr. Ferranti, in making connection with the primaries of his transformer, Mr. Haskins said that four or five methods were in use for connecting on to the concentric mains. The commonest one was a good deal like the branch that a plumber would put into a pipe. The inner tube is brought through a sort of T-joint and carried a good distance before the insulation is removed from it. That gives one leg of the circuit. The other is taken off by an outside ring which is soldered on to the other conductor and goes in the other direction for a safe distance, covered by insulation.

Mr. Ferranti as a rule made his connections with current cut off the circuit, and did not attempt to handle the 2,500 volt wires when they are alive. Where it is found necessary to connect on when the circuit is alive, the double plug fuse is taken out on the primary, as this fuse can be put in with safety when the current is alive.

Mr. J. A. Seely described the method of connection employed by the Manhattan Electric Light Company, of New York City,[2] where they place the primaries in front of their houses and lead to insulated binding posts. In case a subscriber is put in they put in what they call a primary switch, and after the insulation is made and the lamps installed all that is necessary is to close a switch. They also interposed those switches into all their lines now, as the fire underwriters had requested it.

Mr. R. W. Pope then moved the adoption of the following resolutions:

> *Resolved*, That the sincere thanks of the National Electric Light Association be, and the same are hereby tendered, to the publishers and staff of the Providence *Journal*, the Providence *Bulletin* and the Providence *Evening Telegram*, for their very complete and accurate reports of the proceedings of this Convention which have appeared during our sessions in this city.

(Applause).

The resolutions were seconded and unanimously adopted.

Mr. F. A. C. Perrine refering to the rope gearing used by Mr. Ferranti mentioned that there was a very excellent system of rope gearing in use in the Providence Cable Railway power house, manilla rope being used.

Mr. T. Carpenter Smith then read a paper on "The Distribution and Care of Alternating Currents.[3]

In the discussion of Mr. Smith's paper, **Mr. M. D. Law** said that one of the principal causes of bad service, specially in the use of alternating currents, was in poor line construction. Another mistake was made in running lines where other wires are used than those of alterating currents, and in placing the alternating wire on the top; these should be kept down low, as there was not the danger to dynamos from the crossing of wires, as a cross on a direct current wire does not, as a rule, mean any damage to the apparatus. But in the case of a cross on alternating wires it means a burned out armature, unless insulations are especially good, and the circuit is fused very close to its maximum load. He finds this a very important point to look after. He advised the examination of all fuses carefully every day, and never to have the circuits fused to more than ten amperes above record of the daily run.

Mr. Smith had spoken of the necessity of carefully fusing the primaries of the converters. When Mr. Law took hold of the Denver Company he found that in a large proportion of their converters the primary fuses had been taken out, and No. 14 copper wire substituted. In the case of a burn-out in the converter, it would under these conditions mean a burned-out armature. If one had any number of dynamos the ampere load of each circuit should be kept within the smallest unit of the machines. This means the ability to make rapid changes in times of trouble without danger of overloading them.

A great mistake was made in putting the switch-board too close to the wall; especially when the fuses were put on the back of the board, and the board should be so arranged that a man can get out at any time, as it is sometimes rather a hot place, and not a good location to get penned up in. Each and every circuit should be provided with both volt and ammeters as Mr. Smith had stated. And in addition to this it was a good thing to arrange a many-point switch that could, at will, connect a standard Cardew or other voltmeter to any circuit; in fact, this could be done several times a day as the voltmeters in constant use were liable to get out of calibration. This was especially useful if one was placed in the position in which Mr. Law was, where the directors refused to get the copper, which was necessary to even up the loss on lines, and with thirty per cent. loss on one line and only two per cent. on another. In this case the extra voltmeter was absolutely required.

---

[1] See page 237.

[2] For a full, illustrated description see The Electrical Engineer, July 2d, 1890.

[3] See page 211.

Great care should be taken that the exciter wires when they lead from bus bars are amply large, so that there may be no loss between exciter and alternator, or it may require such a high voltage in the exciter circuit that it may be dangerous to the dynamos where such wires are carried under the floor and the floor or the ground do not allow the use of an ordinary wire covered with soft rubber tubing; it is very dangerous from the fact that the oil which gets on them softens the rubber. A better plan is to make a small conduit or trough and thoroughly bed and cover the wires in plaster of paris; this is a good insulator and will prevent the entrance of oil or allow fire to follow the wire. Another important point in the construction of lines is where the primary loops are led off from the main feeder; as a rule, these wires are half spliced on to the main feeder and carried directly to the converter. This should always be done at the pole and such wires so arranged that it is impossible for a cross to occur where the primary wire crosses that of the main feeder; this Mr. Law finds to be a common fault, and in several instances, to his knowledge, has resulted in a No. 6 wire burning entirely through a number 0 wire and dropping the live wire in the street. Great care should be taken that this wire is carefully fastened at the pole in such a position that it will be impossible for a cross to occur.

Mr. A. F. Mason referred to the practice in Great Britain, where converters, contrary to the practice here, were not permitted to be placed outside of buildings. The one exception was the city of Philadelphia, where converters were permitted inside.

Mr. Haskins stated that no trouble whatever had been experienced in England with converters on the inside of buildings.

The President quoted Capt. Wm. Brophy as saying that there was no reason why the converter should not be put in buildings and yet he forbade it in Providence, and his only reason was that with the converter working warm, some of the insulation might smoke a little bit, and some one might cry fire, pull the fire alarm, and call out the department. His company had lost one converter only in the hundreds in operation in Providence, and that one was mechanically defective.

Mr. Smith, in answer to a query of Mr. Mason, said he had been accustomed for some years to regard slate as the best material as a backing for switch-boards, but within a short time he had had an annoying accident happen from the use of slate, owing to the presence of mineral in the slate itself. He had come across a statement that marble should not be used on account of the presence in it of so many veins of mineral, and that slate was the only good material, but he found that the pure white Italian marble could be had in blocks without any mineral in it whatever, and it seemed to him as though that would be the only substance that could be thoroughly depended on, though, of course, quite expensive. For that reason he somewhat favored putting all switches and cut-outs and work of that kind on marble or porcelain bases, but making the switch-board itself of wood, and allowing no wires to be clamped directly to it, and keeping everything off the switch-board two or three inches. An air space of three or four inches protects the board pretty thoroughly against fire. With a board of that kind, if there were danger of catching fire, he would not hesitate to turn the hose on it.

Mr. Smith also advocated an insulation which would not carry fire even though it were not absolutely waterproof, since the switch-board is generally in the driest part of the station.

Mr. Mason drew attention to the fact that any kind of cotton covering when soaked in a solution of tungstate of soda is rendered absolutely incombustible, and he suggested its use in central station work.

Messrs. De Camp, Armstrong and Francisco spoke in terms of high praise of Mr. Smith's excellent paper, and, on motion of Mr. De Camp, the paper was ordered to be printed separately for distribution among the members, and its full discussion postponed until the next meeting. It was also decided to print the discussion of the paper prepared by Mr. M. D. Law at the same time.

Mr. M. J. Francisco paid a high compliment to President Perry on his administration of the Narragansett Electric Light Co., of Providence, which had given that city a central station and a system of electric circuits which were models of their kind.

Mr. S. E. Barton, being called on by the President to state the objection of the underwriters to placing the converters inside of public buildings, said that there was no particular objection. The objection that took in the beginning in New England was perhaps primarily because it was a new thing, and because it was perhaps considered on the safe side to have converters on the outside; they never thought there was any danger from fire in putting converters on the inside of a building. He agreed that the construction of converters to-day was very much superior to what it was in the beginning, and he thought the time had come, perhaps, when it would be better, for many reasons, to put converters in a good, suitable location inside of buildings, and not outside. But he believed it was a wise decision that was made in the beginning, to exclude them from the inside of buildings.

Mr. T. C. Smith drew attention to the fact that much damage had been done to electric lighting interests in this country by the bad construction work existing in New York, and the accidents which had resulted therefrom, and instanced a case in point.

Mr. F. A. C. Perrine then read a paper on "Mutual Insurance of Accounts."[1]

In the discussion which followed the reading of Mr. Perrine's paper, Mr. De Camp said he was very much struck by the suggestions made; they were entirely new, and he felt safe in assuming that the author never had to manipulate the finances of an electric light station. It seemed to him that the arguments did not apply directly to the stations. He did not take it to be the province of the Association to insure against an insufficiency of capital in any business, which was one of the main causes of failure. The second cause of failure of the lighting companies had been due to their income not being sufficient to meet their expenses. That he did not think any Association wanted to put itself in a position to insure.

The competition among the manufacturers of material, had led them to go beyond the bounds of good judgment in extending their credits. In other words, the time came when there was a settling day and settlements had not been had, certainly, in a satisfactory way. There was no mode of insurance that could protect any community against such business methods. (Applause.)

Mr. Perrine referred to the fact that his firm, Messrs. Roebling's Sons' Co., had lost only $1,200 during the past year in a business amounting to over $1,000,000. That proved to him very clearly that the electric light companies were on a firm basis and that they are not companies that, as a rule, one would risk much in trusting. But he had seen cases—more when he was with an electric light company than now—when some of the best business of the company had to be lost; when it was necessary to allow ruinous competition to come into a town, because the stockholders, in spite of the payment of good dividends, and the extensions made out of the earnings, refused to allow any more money to make any more extensions, whereas the business was well worth borrowing the money on to make these extensions. That was practically the idea that Mr. Perrine had; a mutual insurance company of this kind was practically a mutual bank where one would have, not six per cent. for one's money, as fixed by law, but the actual cost of furnishing what was wanted, which is very much below that figure.

Mr. A. J. DeCamp then read the Report of the Committee on Data [2]

The President, as chairman of the Committee on the World's Columbian Exposition, reported that he had notified Director General Davis, of Chicago, of the appointment of the Committee, and of its willingness to co-operate with him in a way to secure the success of the exhibits. He had received a reply that the invitation had been received and placed on file, and at the proper time would be answered by the proper person. The Committee was continued.

The Convention then adjourned until 4 P. M.

AFTERNOON SESSION.

The Convention was called to order and immediately went into Committee of the Whole. On rising, the following officers were elected for the ensuing term:

President: C. R. Huntley, Buffalo, N. Y.; *First Vice-President:* James I. Ayer, St. Louis, Mo.; *Second Vice-President:* M. J. Francisco, Rutland, Vt.

EXECUTIVE COMMITTEE:

Class 1.—E. F. Peck, Brooklyn, N. Y.; John A. Seely, N. Y. City; R. Faben, Jr., Toledo.

Class 2.—Albert J. Corriveau, Montreal; H. H. Fairbanks, Worcester, Mass.; A. J. DeCamp, Philadelphia.

Class 3.—J. J. Burleigh, Camden; A. N. Robinson, Minneapolis; E. W. Rollins, Denver.

The recommendation of the Committee of the Whole that the next meeting be held in Montreal, in the month of August, was adopted, the Executive Committee to arrange the date.

The following resolution, offered by Mr. Shaw, was adopted:
